

## Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

## Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. ### DISEASES OF THE HEART IN CHILDREN.

By W. H. DAY, M.D., M.R.C.P. Lond.;  
Physician to the Samaritan Hospital for Women and Children.

(Continued from page 519 last vol.)

**Diagnosis and Prognosis.**—The diagnosis is easy enough if the case is well marked, and the effusion is serous and moderate in quantity. In such cases as these the patient may make a complete recovery, and be none the worse for the seizure. If the effusion is thick and fibrinous, as we have seen, it may cause roughening, or adhesion of the surfaces. Delirium is an important diagnostic symptom, and when it occurs early in the disease it may lead to the impression that the brain is the seat of mischief. When delirium supervenes in the course of rheumatic fever, it would be a culpable error not to investigate the condition of the heart at every visit—exposing the patient, however, as little as possible. Orthopnoea is also an important diagnostic sign. The disease is very fatal in weak and strumous children.

**Morbid Anatomy.**—There is effusion of serum, sometimes of a transparent lemon colour, or of a reddish tinge, or there is pus in the pericardium with coagulable lymph, and adhesion between the two membranes. The two surfaces when torn asunder at this stage present a honeycombed, or tripe-like appearance. The white spots so commonly found on the surface of the heart after death have been shown by Sir James Paget to arise from previous inflammation.

**Causes.**—As in the idiopathic affection, acute pericarditis is extremely rare, yet it does now and then occur, and may escape detection in the absence of pain about the heart; as an accompaniment of acute rheumatism it is very common. "In 5 cases of pericarditis, in 2 of acute, and in 4 of chronic endocarditis, and in 2 more in which both the pericardium and the endocardium were involved, making a total of 13 out of 39 cases, or exactly 1 in 3, rheumatism was certainly known, or alleged on good

grounds to have been the starting point of the mischief." (a) "Of pericarditis not in alliance with rheumatism, Crovisart gives five cases, and it was complicated with inflammation of other parts in all of them except one, and in this it was caused by a severe blow upon the region of the heart." (b) It may arise from the extension of pleurisy or pneumonia, or be associated with renal disease, chorea, measles, or scarlatina. (c) Andral has met with it as a complication of small-pox, and in the last stages of tubercular disease of the lungs with vomicae, and with chronic asthma and bronchial congestion. A case in which the pericardium was greatly inflamed, and contained an abundance of turbid yellow serum and lymph, is recorded by Dr. Dyce Duckworth. The child was only eight months old, and the disease appeared to follow on enlargement of the bronchial and mesenteric glands. After death, no tubercle was found in the pericardium or brain, but it was general in the pleurae, lungs, liver, and spleen. (d)

**Treatment.**—The objects to be aimed at are to reduce the inflammation, and to favour the absorption of the effused fluid. Leeches may be applied to the cardiac region in strong subjects, and there can be no question of their service where the pain is very acute, and the pulse is frequent and hard, but venesection is never necessary

(a) West "On the Diseases of Infancy and Childhood," 1859 p. 481.

"In 2 cases of pericarditis, in 3 of acute, and 1 of chronic endocarditis, or in 6 out of 39 instances, the disease of the heart was traced to an attack of scarlet fever. The cardiac symptoms did not manifest themselves in the acute stage of the affection, but during the process of desquamation. They were accompanied by fever and anasarca, which, however, did not exceed mere puffiness of the face and extremities, until, in the two instances of pericarditis, both of which ran a chronic course, dropsy came on as the consequence of the heart disease."—*Ibid.*

(b) Dr. P. M. Latham, "On Diseases of the Heart," New Syd. Society, 1876, vol. i., p. 219.

(c) "Pericarditis is not frequent in cases of acute Bright's disease from scarlet fever in the young, since it only occurred in 1 in 14, or 7 per cent. of the patients under 16 years of age."—Sibson, "On Pericarditis, Reynold's System of Medicine," vol. iv., p. 408.

(d) "Path. Transactions," 1875, vol. xxvi., p. 246.

in children, however robust they may be, because reduction of the strength has to be feared, especially as the complaint frequently follows rheumatism, when the constitution, already low, will not bear further depression, and the blood, in many instances, is poor and aqueous. A strong mustard poultice is about the best application; its action is quick, it can be obtained at a moment's notice, and when the child complains of the smarting it may occasion it can be removed at once. In two cases of acute pericarditis accompanying rheumatic fever in children, aged respectively eleven and thirteen years, I found these poultices act most beneficially, quickly relieving the præcordial distress and uneasiness, and I believe controlling the effusion. The chest should be covered with cotton wool immediately the poultice is removed.

The next remedy of service is counter-irritation. I should not hesitate to employ a blister whilst the skin is reddened from the rubefacient effects of the mustard; indeed, I think this is the time to apply it. The surface should be painted over with strong blistering fluid, and the chest protected afterwards with cotton wool. I have never known it do any harm, but the late Dr. Sibson was opposed to blistering, on the ground that it inflicted local injury, tainted the blood by increasing its fibrin, and prolonged the inflammation. He strongly advocated "the application of chloroform over the seat of suffering, combined with belladonna liniment, sprinkled on cotton wool, and covered with oiled silk."—(Op. cit., p. 433.) After the action of the blister, an ointment composed of equal parts of savin and mercurial ointment should be spread on lint, and applied to the præcordial region. Another excellent application, after the blister has risen, is a combination of mercurial ointment and powdered opium (ʒj. ad ʒj.) recommended many years ago by Dr. Beale.

Hot fomentations are unsatisfactory, because they necessitate exposure of the patient's chest during their employment, and it is doubtful whether they can be borne hot enough to be of any benefit. Then there is the danger of getting a cold or chill, which ought to be guarded against, and so likely is this to happen that, if the case goes on satisfactorily, it is a great mistake to institute frequent stethoscopic examinations of the chest.

Mercury may be given as an aperient, but not with the view of fulfilling any special indications, and in rheumatic cases it requires great caution. If inflammatory fever runs high, and there is thirst, elevation of temperature, and scanty turbid urine, then a general antiphlogistic treatment may be carried out, and aperients, diuretics, nitrate, and bicarbonate of potash will be required. Even aconite is sometimes useful if the skin lacks moisture, and quinine may be given advantageously in small doses, if the temperature is disposed to run high, and there are indications of exhaustion.

Opium should be employed if there is much pain, as the continuance of it further reduces the strength of the patient, it diminishes the cardiac contractions, and controls the hurried circulation; but if the heart gets feeble, the respiration hurried, and the countenance at all livid, then stimulants, in the form of wine or brandy, ammonia, and ether, will be required.

*Chronic pericarditis* is usually a sequel of an acute attack of rheumatic fever, and is not frequent in children. The chief symptoms are pain in the region of the heart, and inability to lie on the left side, or with the shoulders low. The changes produced in the pericardium where the acute attack has not ended in resolution, are thickening or adhesion of the pericardial surface, and effusion of lymph or pus. In consequence of this change the action of the heart is embarrassed, and the muscular structure of its walls becomes hypertrophied. When adhesion takes place, the action of the heart is rolling or tumbling, and it can be observed over a large space: the apex is seen beating in the epigastrium, which is retracted. With these changes the face is often dusky and anxious, and if with the acute pericardial attack the endocardium

has been also involved, we may have evidences of valvular disease.

The *treatment* consists in meeting the symptoms that arise, by blisters to the chest, active saline aperients to relieve the oppressed circulation, and anti-rheumatic remedies, as iron, quinine, and iodide of potassium.

Pericardial effusion may be the result of acute or chronic pericarditis. The physical signs are a gradual increase in the transverse dulness just below the base of the heart, and displacement of the lungs. The dulness may extend across the thorax from the right nipple to the line of the left axilla, and as high up as the top of sternum. "And in all pericardial effusions, whether great or small, it is the upward extension of dulness which affords the means of diagnosis from enlargement of the heart.

The amount of effusion by separating the heart from the chest wall causes its impulse to be weak, and bulging of the præcordia may ensue. The liver, spleen, and diaphragm are depressed. Adherent pericardium leads to dilatation and hypertrophy of the heart.

The symptoms in the case of a lad, æt. 13, who came under my notice in 1864, were as follows:—The patient was suffering from rheumatic fever. On the fifth day of the attack, acute pericarditis came on, and four days later there were all the symptoms of extensive pericardial effusion. The patient had to be propped up in bed from the severity of the dyspnoea, and he could not lie down for a moment without threatening suffocation. The pulse, throughout small, became fluttering, and for some hours imperceptible at the wrist; the skin was bathed in sweat, low muttering delirium was frequent, and the patient's life was despaired of. The dulness extended nearly across the sternum from one nipple to the other, and as high as the second rib. The heart's action could not be detected, but there was no palpable prominence of the præcordial region. The patient recovered without any after bad effects, either local or constitutional.

The *treatment* consists in giving aperients and diuretics. Blisters and counter-irritants should be applied to the chest. When there is no chance of the effusion becoming absorbed, an aspirator should be passed through the fifth intercostal space, and some of the fluid drawn off. (a)

An interesting case of pericardial effusion is recorded by Dr. Barlow, in a boy six years of age. "Twice the pericardium was tapped by the aspirator, and twice the abdomen, with marked effect, and without any bad effects from the operation. The child was feverish throughout, and neither the fever nor the considerable ascites could be satisfactorily explained during life, but after death these were found to be due to tubercular peritonitis. (b)

The purely passive form of effusion from obstruction to the circulation presents the same symptoms, and the treatment is also similar.

#### ALCOHOL AS AN ANTISPASMODIC. (c)

By BENJAMIN WARD RICHARDSON, M.D., F.R.S.,  
President of the Medical Temperance Association.

In my essay on Intermittent Pulse, written twelve years ago, I expressed, on the subject of treatment, that alcohol was the sheet-anchor of treatment in extreme cases, and I gave a formula for its administration which has been very often used. Since I have taken up the advocacy of the principle of total abstinence from all alcoholic drinks I have been challenged in respect to the above-named passage as if there was something in it entirely contradictory to my present views.

Such contradictory method does not, however, lie for a

(c) Essay read at the First Meeting of the Session 1880-81 of the Medical Temperance Association.

moment at my door. No man can lead an active out-spoken life and at the same time a life of continued learning (in which the student's is always the first part), without finding that something he has said requires correction, or it may be retraction. Conscious of this fact I have ever aimed respectfully to follow the best examples of men who, under a like experience, have been obliged to take action on themselves, and at once to correct or to retract altogether whatever in my own mind and clear judgment I have seen occasion to recall.

In the present instance there is no necessity either for correction or for retraction. Between the general use of alcohol as a supposed food or luxury, and its use as a medicinal agent, there is the broadest distinction, a distinction as broad as that which exists between opium as a food to the opium eater and opium as a medicine for the sick, I have never given up the medicinal use of alcohol. On the contrary, it has been my steadfast duty to learn, with all possible accuracy, the therapeutical value which alcohol really possesses; to compare it, in respect to its action, with other medicinal agents with which it is therapeutically allied, and to make sure when to administer it and how to administer it with prospect of good and certain success.

In this sense I have specially devoted my attention to the study of alcohol as an antispasmodic. If alcohol have any particular medicinal virtue it must be in this direction of action,—I mean as an antispasmodic,—that it is most useful. All our physiological observation upon the effects of alcohol point in that direction. Alcohol relaxes. It relaxes the arterial vessels to their extreme subdivisions: it relaxes muscles until they fail to respond to their nervous stimulus. "Helplessly drunk" is the common phrase employed to designate the man or woman who is paralysed by alcohol.

Alcohol relaxes the organic muscular fibre so completely that the relaxation induced by it extends even after death. In performing one of my experiments for what I called in my communication to the Royal Society on resuscitation in 1865, *artificial circulation*, I found that when a rabbit was suddenly killed in the usual way by a blow on the back of the neck, such was the resistance due to the shock exerted on the blood-vessels it was easier instantly after death to rupture the aorta by the pressure of an injected fluid than to inject fluid over the arteries into the veins. I found also that the diffusion of some agents over the body immediately before or immediately after death intensified this resistance while others reduced it. Chloroform and all its allies of the chlorine group intensified it. The alcohols, methylic and ethylic, and their respective ethers, together with methylal, amyl nitrite, and some other analogous bodies, so reduced it, that the injection through the minute circulation was most easily effected.

Comparing these facts I was led almost immediately after my first experiments with amyl nitrite in 1860-2, to put alcohol and the nitrite in the same position as relaxing chemical agents on organic and voluntary muscular fibre. Thus, therapeutically, alcohol came under the old head of an antispasmodic, and it is as such that I have since more carefully studied its clinical value.

In making this explanation I do not wish to assume that alcohol is of no other medicinal use than as an antispasmodic. It is an antiseptic. It reduces the animal temperature, and in that respect may be considered a febrifuge. It coagulates blood and albuminous fluids, and in that sense may be called a styptic. Its values in all these directions are different and, perhaps in all, comparatively little when tested by the side of other agents; but I leave these considerations to keep to the great one,—its service as an antispasmodic.

In this regard ethylic alcohol holds a place peculiar to itself. It acts very much more slowly than amyl nitrite, ethylic ether, or methylic alcohol. For that same reason the relaxing action is much longer held on. Thus, in sharp spasms, such as that of angina, colic, tetanus, asthma, the action of amyl nitrite is quick, determinate, and at the same time evanescent, while the action of alcohol is too

slow to effect relief in any such space of time as would prove to be useful during emergency. What is more, the quantity of alcohol that is required to produce a relaxing effect in such cases is so great that other evils are apt to arise from the complication.

It is scarcely correct, therefore, to say that alcohol is a good antispasmodic in cases of acute, tonic, or tetanic spasm. But in such cases it becomes a convenient and compatible vehicle for the more active direct antispasmodics, and as such I frequently prescribe it. Thus, in pure spasmodic asthma, I commonly order for an adult the following mixture:—

Amyl nitrite, m. iij. ;  
Alcohol, sp. gr., '830  $\bar{3}$  ss. ;  
Distilled water,  $\bar{3}$ i. ss.

To make a draught.

This, with more water added to it, to render the dose agreeable to the taste, is very rapid in its action. I have at the present time a patient suffering from spasmodic asthma, who for two years past has always carried this compound with him. He has invariably some preliminary indications of an acute attack in the form of constriction across the chest, rapid and strong action of the heart, and coldness of the hands and feet. Before he took the remedy above named he found more relief from a sharp walk, or even a run, than from any other course of treatment, and he sometimes could stave off an attack by this plan. Now he at once takes his draught in cold water—ice-water if he can get it—drinking it slowly, and he so certainly obtains the desired relief, that for fifteen months he has not had one continued attack. In this instance the alcohol keeps up the action of the nitrite, and this mode of administration contrasts well with the mode of administration I originally suggested, by inhalation. He first was treated by inhalation of the nitrite, and so obtained relief, but it was a temporary relief only and not comparable in result to the present method. In this instances the sufferer is a total abstainer from alcoholic beverages, for which reason so small a dose of alcohol as half a fluid ounce suffices, often without repetition, to keep up the relaxation. He is, however, instructed to repeat the dose every half-hour for three times, if relief should not follow at once. A few times he has been obliged to take a second portion.

I have followed the same mode of using alcohol with the amyl as antispasmodic in cases of angina pectoris, but I cannot say with the same good result. Paroxysms of angina in those who are subject to them are so terrible that they keep the sufferer ever on the point of expectation and dread that they are about to occur. The result is that patients constantly have resort to the alcoholic remedy, a practice which in truth leads to two bad results. In the first place, a craving for alcohol is soon created. In the second place, that craving once established itself keeps up a condition of alcoholism which is most depressing; which promotes trepidation and anxiety, and which prompts the seizure. Further than this the alcohol, if long continued, keeps up a form of acid dyspepsia, during which the urine becomes charged with uric acid, the secretions of the skin are made very acid, and the whole body is thrown into a state of rheumatic or rheumatoid disorder. Lastly, the effect of the alcohol as a continued antispasmodic is soon lost, unless the dose be steadily increased, when the action of the amyl is, from the dilution, itself also reduced in efficacy.

Except, therefore, in rare instances, I have given up the employment of alcohol as a menstruum for amyl nitrite in angina, and have returned to the plan of administration by inhalation—a plan that usually leads to instant relief, does not cause dyspeptic disturbance, and does not lose signally in its effect, even after several months,—I had almost said years,—of employment. I have, in fact, a case of angina in which, after two years and eleven months, the nitrite has, on every occasion, at once subdued the spasm.

Let me, in parenthesis, dwell for a moment on the

question of loss of effect from medicinal substances. This, as I think, turns greatly on the solubility of the substance in the blood, and the fluids of the tissues. If the substance be very soluble, so that great portions may be taken before there is saturation, the effect first produced is soon liable to be lessened unless the quantities be increased, whereupon there is, in time, set up by it a series of systemic changes which are physiologically different from those which, in the first instance, were simply useful. If, on the other hand, the substance is practically insoluble in the blood and fluids of the tissues, the secondary effects due to increasing absorption are avoided, and the agent continues to exert its primary influence from much the same dose for a long, and practically an unlimited period. Alcohol and amyl nitrite are examples of this rule. Alcohol, easily absorbed and diffused, requires an increasing dose, leading to new and unnecessary phenomena. Amyl nitrite, comparatively insoluble, repeats its action again in the same manner, and with good effect. Anhydrous ether, another antispasmodic, resembles amyl nitrite in this respect, but, being more soluble, not so completely. Ether may, however, be repeated an immense number of times without losing its effect, and without exciting systemic changes or structural devastations.

The diffusibility of alcohol in the blood and through the body renders it, therefore, a bad antispasmodic where it is often required. But this very fact of diffusibility makes it as useful in other cases, when an equable diffusion through the body is the best line of practice to be pursued. In illustration I may mention examples of shock or stun, mental or physical, as cases in point. During shock, as from a blow or from fright, the pallor of the face indicates the resistance that has occurred in the terminals of the circulation, while the heart, sharing, through its vessels, in the same catastrophe, is unable to meet the strain to which it is subjected. Here alcohol acts perfectly as a restorative, when it can be administered and absorbed. Diffused through every part, it causes a relaxation, under which the heart is relieved, the circulation is set free, and the animation is restored. In short, just because a man intoxicated from alcohol bears shocks which might be fatal to a sober man, so a man under shock is relieved by alcohol. In the first instance the body was in a condition under which the organic motor fibre is enfeebled by the alcohol, and rendered irresponsive to the concussion; in the second instance the contracted organic fibre is relaxed by the alcohol.

It is no paradox to say that in this particular mode of action, in cases of stun, alcohol resembles blood-letting. The old practitioners drew blood from persons who were stunned by physical or mental shock, and if they succeeded in getting a current of blood they were accustomed to witness a quick reanimation. I have seen this phenomenon myself in the early part of my career. What occurs from this process is relief to the right side of the heart, with removal of pressure and of resistance to the heart-stroke, so that the heart is enabled to rekindle motion. The relaxing influence of alcohol is of the same character of relief.

For a similar reason alcohol is a good agent to administer just before the administration of those anæsthetics which produce contraction of arterial fibre and convulsive spasm. This action belongs to all the members of the chlorine anæsthetic family, to chloroform singularly, and is no doubt, as I have pointed out over and over again, the chief cause of danger from them. To give a dose of alcohol therefore, a dose sufficient to produce a demonstrable physiological effect, before administering chloroform, is sound physiological practice; and I attribute much of the success which attended the administration of chloroform in my hands to this detail. I noticed so often that a full dose of alcohol lessened the duration and intensity of the second or convulsive stage of chloroform, that I invariably gave a full dose before beginning to apply the inhaler. In my lectures on *Materia Medica*

to the Royal College of Physicians I made this point a matter for direct demonstration. I showed the action of chloroform alone, of ether alone, and of chloroform after a subcutaneous injection of alcohol, on the hearts of three guinea-pigs that had been let sleep to death in the vapours. In the animal that had died under chloroform alone the heart was dead and the lungs pale: in the animal treated with ether alone the heart was beating briskly on the two sides, and the lungs were filled with blood. In the animal that had been treated first with alcohol and then with chloroform the heart was beating regularly on both sides, and the lungs were filled with blood.

Again, I showed an analogous experiment in my experimental lectures on Artificial Respiration. I showed two rabbits that had been made to cease to breathe in chloroform vapour, but one of which had previously been injected with alcohol. I started the process of artificial respiration in the two at the same time, as they came out of the narcotising chamber; and demonstrated that while the one that had been charged with alcohol was restored with the utmost readiness, the other was hopelessly beyond restoration.

The antispasmodic action of alcohol is here shown at its best, and I should still, were I about to take or to administer chloroform, prescribe a preliminary dose of alcohol. For ether and nitrous oxide such a precaution would not be necessary; for methylal it would not be necessary. Those agents themselves play the same part as alcohol; they relax the arterial fibre.

(To be continued.)

#### ACUTE LARYNGITIS DURING THE CONVALESCENCE OF SMALL-POX. (a)

By KENDAL M. St. J. FRANKS, F.R.C.S.I.

Surgeon to the Adelaide Medical and Surgical Hospitals, Dublin.

LARYNGEAL complications in small-pox are not at all uncommon, the frequency with which they occur varying with the type of the epidemic. In the epidemic in Dublin in 1871, laryngitis was found in a large number of cases, and to it a great number of the fatal results were due. In the epidemic which lately visited this city, Dr. Harvey, one of the physicians of the Cork Street Fever Hospital, informs me that it occurred frequently, and was almost the rule in the confluent cases. It does not appear, however, to have been particularly severe, the fatal cases being generally complicated with some pulmonary mischief, especially with pleurisy. In every epidemic one thing is certain, that the severity of this complication, as well as the particular kind of laryngitis, depend on the period at which the complication occurs, and that the earlier it appears the milder is its course. It seems to be of three forms: firstly, a pustular form appearing about the sixth day of the disease, or a few days subsequently. In it the larynx shows signs of inflammation—not very severe—and on the mucous membrane more or less distinct pustules may be seen; sometimes confluent, sometimes discrete. It is probably an extension from the mouth and pharynx. This pustular laryngitis may come on in cases of small-pox, even when it otherwise runs a normal course, and in a few cases may prove rapidly fatal. Trousseau mentions the cases of three small-pox patients, who, on the eighth day of the disease, were suddenly seized with a fit of suffocation, which carried them off in a few seconds before there was time for any one to come to their assistance. In one of them an autopsy showed indications of inflammation of the larynx and variolous pustules below the glottis. This form, however, in the majority of cases, causes little or no inconvenience.

(a) Read before the Surgical Society of Ireland. Discussion will be found on page 10.

The second form is an acute laryngitis coming on between the ninth and twelfth days of the disease, about the period when the swelling of the face has reached its maximum. It is a complication of confluent small-pox, and is often preceded by a confluent eruption on the mucous membrane of the throat and larynx. It is characterised by extensive inflammatory exudation into the sub-mucous tissue of the larynx, causing the parts to look thickened, tumefied, and red, sometimes completely blocking up the opening. The symptoms of suffocation may be so rapidly developed that a fatal issue may ensue before relief can be obtained, or on the other hand, the laryngitis may pass into a subacute form, and be so insidious that urgent symptoms may not be developed for a considerable period. It is illustrated by the case which I bring before you to-night.

The third form is the most alarming, and was first described by Dr. Rühle, who made fifty-four post-mortems in one epidemic. He considers "the essential peculiarity of the laryngeal affection to be of a croupous or diphtheritic inflammation. Dr. Morell Mackenzie has known permanent paralysis to have followed two cases of small-pox in which the larynx was affected. In these cases, usually beginning about the tenth day of the variola, we find acute inflammation of the larynx, with infiltration of the ventricular bands and aryteno-epiglottidean folds; such that in a short time the whole opening in the larynx may be closed up, the mucous surfaces being covered with false membrane. This condition is exceedingly dangerous, and treatment is so often of no avail that Dr. Mackenzie (a) says it is almost useless. Dr. Harvey tells me that in the Cork Street Fever Hospital during the past few years, he has often known the pharynx and tonsils to be covered with diphtheritic membrane, but he had no opportunity of examining the larynx. He looked upon it as diphtheria complicating small-pox, and treated it as such, most of the cases doing well.

The case which I am about to bring before the notice of the Society forcibly illustrates the second form. I have alluded to, and is interesting as illustrating the slowness with which the laryngitis developed and threatened to destroy life, as well as from the subsequent progress and results of the case.

Mary M., *æt.* 37, married, and the mother of a large family, was admitted to the Throat Hospital on the 12th of February, 1879. Eleven weeks previously she had been admitted to Cork Street Fever Hospital with confluent small-pox. Laryngeal troubles appeared during the fever, but were not severe. As far as I could find out, they dated from the eleventh or twelfth day. When she recovered sufficiently from the variola she was moved into the convalescent ward, about seven weeks after her admission. She remained in this ward for about four weeks more, during which time, the laryngeal symptoms becoming gradually worse, leeches were applied over the thyroid cartilage, and she was ordered to keep the throat poulticed. On Saturday, February 8th, she left the hospital contrary to the advice of the medical officers. On the 10th she applied at the general dispensary of the Adelaide Hospital, where she was examined by Dr. Walter Smith. At his request I saw her at the same time. We found enormous œdema over the arytenoids, with great inflammatory swelling of the ventricular bands. There was only a very small chink for breathing. We told her that she should at once get into hospital as an operation might be required at any time, and I gave her an order for admission to the Throat Hospital in York Street. She however did not seek admission till two days later, when the dyspnoea became so urgent she thought she was choking. I saw her on Thursday morning in company with Dr. Pope. She was placed in a warm room, with steam playing about the bed, and poultices kept constantly to the neck. On examining the larynx the condition of the parts was much the same as that previously noted, only now the space through which

she breathed was scarcely larger than a crow-quill. The front of the neck was swollen and tumid; the skin brawny. It was almost impossible to make out the margin of the thyroid cartilage with the fingers. Moreover, she stated that for the last two days she had not been able to swallow, even fluids. She was accordingly fed during the day with nutrient enemata. On visiting her again at 5.30 p.m., she did not seem worse, so we determined to continue poulticing and vapour, and to postpone operative measures till they might become absolutely necessary. At 8.30 I was summoned, as she had had a bad attack of spasm, and had grown livid. Dr. Walter Smith came with me, and with his assistance and that of Dr. Pope I determined to operate at once. Chloroform was administered, but on attempting to keep up its effects with ether, spasm came on. On raising the mask the face was discovered to be quite livid, and breathing to have ceased. We thought life was extinct, as she had become pulseless. However, taking the line of incision from the centre of the chin and top of sternum, I rapidly made an incision, an inch and a-half long, down to the trachea with a Worthington's knife, and then plunging into the trachea I pushed on the director. The hæmorrhage was trifling. Instantly she drew a long breath, and when the spasmodic coughing—incident on opening the trachea—had subsided, she seemed greatly relieved. I found considerable difficulty in trying to pass a Durham's canula along the director, but this difficulty instantly disappeared when I substituted my finger for the director. I stayed with her the whole night, and kept a piece of flannel, wrung out, every ten minutes, in hot water, over the mouth of the tube. Nutrient enemata were given every two hours, with a teaspoonful of brandy in each. At 3 a.m., the pulse was 116, full and good. Respiration 26, and easy. The temperature 101°—the highest point reached. The next day I left her in charge of Mr. William F. Elsner, who paid great attention to the case. In the evening the temperature was 100·8. From this time the temperature gradually fell, and became normal the fourth day after operation. Recovery now proceeded uninterruptedly, save for diarrhoea of a very fetid character, which came on on the 15th, two days after the operation. The diarrhoea was checked with ten minims of laudanum administered in each enema, but the fecor only disappeared after a large enema of gruel had been given.

The dysphagia, from which she had suffered two days previous to admission, continued for the following seven days, during which period she was fed exclusively *per rectum*. On the 18th of February, she was able for the first time to swallow a little nutriment, and on the 22nd the enemata were discontinued, and she was fed entirely by the mouth. The dysphagia was not caused by any obstruction to the passage of the food, but to the violent fits of coughing which every attempt at swallowing induced. On March 6th she complained of pain over the thyroid cartilage, and there was a great deal of induration in this situation. The next day the swelling had increased, and the surface had become red and tense. Two days later fluctuation was distinct. I opened the abscess at once and evacuated a good deal of pus—about two ounces. The next day she declared she felt better than she had done since she came into hospital.

On the 15th of March, one month after operation, an examination of the larynx showed the following state of affairs:—The epiglottis was very pale and uninfamed, there was no œdema of it or infiltration of any kind. The mucous membrane covering the arytenoid cartilages and forming the aryteno-epiglottidean folds was of a dusky red colour, and somewhat infiltrated, though not to so great an extent as before operation. The ventricular bands, or false vocal cords, were densely infiltrated, and of a bright red colour. They met in the middle line, the right one being more swollen than the left. Posteriorly between the bands and the arytenoids there existed a small opening about the size of a crow quill. The vocal

(a) Reynold's System, Vol. 3, p. 455.

cords were completely hidden from view. The voice was quite aphonic; she complained of a good deal of cough, and the expectoration through the tube was very foetid. The tube had to be frequently removed and cleaned, as it got quickly blackened and coated inside with thick tenacious mucus.

The local treatment adopted now was in the first instance—iodoform. This was dissolved, nearly  $\mathfrak{zj}$ . in  $\mathfrak{zj}$ . of ether, and this was applied to the larynx every second day. The moment the solution reached the mucous membrane the ether evaporated, and left a fine film of iodoform all over the parts. Whenever any increase of congestion was noticed, a solution of chloride of zinc, 40 grains to the ounce, was substituted. This treatment was continued to the 2nd of April, by which time the ventricular bands had lost a great deal of their bright red colour, and were beginning to assume much the appearance and form of chronically hypertrophied tonsils. I now determined to try and burn these tumefied bands away, and I began with the terchloride of antimony. This caused some pain, which soon subsided after each application. On May 13th nitrate of silver, fused on to the bulbous end of a silver laryngeal probe, was substituted for the terchloride, and repeated in five days. The antimony was not again resorted to till June 24th, when the lunar caustic was used freely, and repeated on the 26th. Subsequent to this latter cauterisation the voice sounded for the first time. In two days it had become fairly strong, though very hoarse. Large ulcers were seen on the inner surfaces of the tumefied bands. The nitrate of silver was employed with occasional intermissions up to the end of July, when I sent her for a fortnight to the convalescent home. Once only an acute attack followed the free use of the caustic, and as this subsided the voice was found to have gained in strength. During these treatments she was taking cod liver oil persistently.

On her return from the convalescent home the larynx was examined, and a great improvement noted. The lumps had shrunk a good deal, and the opening between them and the posterior laryngeal wall had increased in size, so as to be as large as the tube in the trachea through which she breathed. During the next three months the larynx was brushed out about twice a week, either by myself or by one of my colleagues at the Throat Hospital, Dr. Pope or Dr. Peel. At the end of this time, as little progress had been made, I determined to try the local effect of tincture of iodine. The opening, though a little larger than the tracheal canula, did not allow of the cords being seen, the voice having scarcely gained anything in tone or strength since she had been at Stillorgan. On October 25th, eight months after operation, the first application was made. It caused but a short spasm, and the pain was not severe. It was used two or three times a week. At the end of a month, when she essayed to speak, and closed the canula with her finger, about the posterior third of the vocal cords came into view. On the 10th of January of this year, eleven months after operation, I fitted a cork into the canula, with directions to keep it in all day if possible, but to remove it at night. This she was able to do, and continued doing so till the 14th of February. Though, apparently, the tube might have been removed with safety during this period, I preferred to leave it in its place, firstly because I was still using the iodine, and this could be applied more freely as long as she had the tube to breathe through, and was thus protected against spasm; and secondly, she was *enervate*, and expected her confinement about the middle of February. This expectation was realised on the 16th, just a year after the tracheotomy. All passed off well. While she was confined to bed she kept the tube uncorked, but as soon as she was able to go about she kept the cork *in situ* day and night for a week. As it then broke, she removed it altogether, and presented herself at the Throat Hospital on the 13th of March last. The opening in the larynx looked much larger; the vocal cords could be seen, about half of their length moving freely. The ventricular

bands, though still tumefied anteriorly, had shrunk posteriorly so as to leave a good breathing space. There was no sign of inflammation anywhere, the larynx being, if anything, anæmic.

Accordingly, on the 20th of March, I removed the canula altogether. The external wound soon closed up. This was thirteen months and some days since the operation. Since this date I have frequently seen her, and applied tincture of iodine to the larynx. She has had no sign of a relapse. I have not now seen her for two or three months, but have heard that she is at home with her children, and suffers no inconvenience from her throat.

The case is, I think, interesting, as illustrating (1), a result not often attained in the virulent form of laryngitis following small-pox; (2), the long and tedious treatment often necessary to bring laryngeal cases to a successful issue; and (3), the value of the local use of iodine in tumefactions in the larynx, and the comparative safety with which it can be applied.

## Clinical Records.

### VICTORIA PARK HOSPITAL FOR DISEASES OF THE CHEST.

#### *A Case of Pleurisy with Endocarditis and Pericarditis—Autopsy.*

Under the care of Dr. PEACOCK.

MARY C., *æt.* 26, general servant, was admitted into Victoria Park Hospital on December 6th, with the following history:—

She had been quite strong until two months ago, when she had an attack of pleurisy on the left side, accompanied by a severe sore throat. Since that time she had had a cough with muco-purulent expectoration and streaky hæmoptysis (the blood probably proceeded from the throat); she had also suffered from pain in the back and lower part of the chest, palpitation and night sweats, and had lost flesh. There had been no diarrhœa.

On the 3rd of December she had a shivering fit and a pain over the mid-sternum. There had been occasional swelling of the feet and legs for three weeks. The patient was an only child and knew nothing about either of her parents.

On admission, she weighed 5 st. 13 lbs., height being 4 ft. 10 in. There was much emaciation. The pulse was regular, 140. The temperature in the evening was 102.4, but on the next day it fell to 99 deg., and afterwards remained normal. There was some œdema of the feet and legs, which pitted slightly on pressure. The urine contained about one-fourth albumen, and a very few granular casts were seen under the microscope; it was acid, specific gravity 1010, abundant in quantity, but not passed unusually often.

Physical examination of the chest: Heart's impulse in the fifth interspace and nipple line, somewhat diffuse. The cardiac dulness was of a triangular shape, reaching as high as the third costal cartilage, and a little to the right of the sternum. A loud presystolic murmur was heard at the apex, and a distinct to and fro rubbing sound over the fourth left costal cartilage. Apex of the left lung impaired resonance, breathing harsh; some rhonchi. Left and right axillæ a little sharp crepitation heard on drawing a deep breath; the same signs at the right base. Left base impaired from the angle of the scapula, dull from the ninth rib; vocal vibrations diminished; respiratory murmur not heard, but loud pleural creaking sounds heard on drawing a long breath.

Dec. 10th.—Considerable dyspnoea came on suddenly yesterday evening, and has persisted since with more or less abatement. The presystolic murmur no longer audible, otherwise the physical signs are unchanged. The abnormal sounds at the apex appear to vary considerably in time, being at one time systolic, at another time diastolic.

11th.—Respirations 42 per minute. The patient considerably cyanosed. Pulse very regular at the wrist, both in force and frequency, though the heart's action appears to be regular. Pulse very small, still the same quantity of albumen in the

urine, *i.e.*, one-fourth. Præ-systolic murmur heard at the apex, and variable pericardial friction sounds. Moist and dry sounds over the upper lobes of both lungs; dulness posteriorly at both bases; vocal vibrations absent, breath sounds feeble and distant, occasional sharp crepitation. Patient vomited several times yesterday and this morning.

12th.—Patient died rather suddenly this morning at 2 a.m. She did not appear to lose consciousness at any time. Autopsy made fourteen hours after death by Dr. Armitage, Senior Clinical Assistant. Both pleuræ were found to be one-third full of a yellowish serum. There was slight adhesions at both apices. The lungs contained air everywhere, but were congested and compressed, especially the lower lobes. The pericardium was everywhere adherent to the heart by a layer of recent lymph. The heart was very large, and the left ventricle much hypertrophied. The mitral valve was much thickened and contracted, only allowing the finger to pass through it. Liver large, pale, with a slightly nutmeg appearance, kidneys small, capsule thickened and adherent, and traversed in various directions by whitish bands, which extended into the subjacent tissue. Cortical substance throughout much hypertrophied. Small round pigmented scar on left side of os uteri, inguinal glands enlarged. Diagnosis: Mitral stenosis, granular kidneys, pericarditis, double pleurisy.

Remarks.—The enlarged glands and uterine scar pointed to syphilis, and the scars on the kidney, though they may have been infarcts, would also be accounted for by the supposition of syphilitic perinephritis. This hypothesis might also account for the occurrence of granular kidney in so young a person.

### EXCERPTS FROM CONTINENTAL JOURNALS.

Translated by ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

#### PRESENCE OF FOREIGN BODIES IN THE AUDITORY CANAL.

At the last meeting of the Surgical Society of Paris M. Despres read a report of a work by Dr. Roustan, Fellow of the University, Montpellier, on "The Presence of Foreign Bodies in the Auditory Canal." The author has frequently had occasion to extract foreign bodies, such as haricot beans, peas, cherry-stones, &c., which children are so prone to drop into the ear. He has found the classic treatment, injections of water, by no means satisfactory though recommended by all writers on this subject. He has, on several occasions been obliged to use instruments, forceps, curettes, &c., to extract the foreign bodies.

M. Despres considers that the observations of M. Roustan, are neither sufficiently numerous nor sufficiently conclusive to induce surgeons to abandon a treatment which has almost invariably been attended with success, and of which the utility has been proved by experience. Injections of warm water, employed at the outset, and shortly after the introduction of the foreign body, seldom fail to eject it, always excepting, however, those cases in which this body is a hygrometric substance, such as a haricot bean. This treatment has proved successful even in cases where the foreign body had been long present in the auditory canal, or when it had been forced far in by the untimely use of instruments. Injections have frequently led to extraction even when all other means had failed.

M. Gillette succeeded in extracting, by injections of water, a pea, which for seven years had lain within the ear of a little boy. Many fruitless attempts had been made to extract it by means of various instruments. Daily injections directed along the upper portion of the auditory canal forced out the pea although it had increased in volume and had sprouted. This child entirely recovered his hearing, the membrana tympani having fortunately remained intact in spite of the long presence of the foreign body.

M. Terrier remarked that it is not always possible to eject a foreign body from the auditory canal by injection, as in some cases this body, either through its size or through the inflammation determined by it in the tissues, completely obliterates the auditory canal. In the latter case it may happen that, when inflammation ceases or suppuration supervenes, it may happen, he repeats, that the foreign body, though it has till then resisted all methods of extraction, yields at once to a new style of treatment. Injections can be successfully employed only in those cases where

there is a certain amount of space between the foreign body and the inner extremity of the meatus externus as the water can thus accumulate behind the foreign body, and consequently force it out.

M. Marjolin has frequently extracted foreign bodies by means of wire bent in the form of a fish-hook. The instruments generally used for this purpose, forceps for dissecting or dressing, are defective, the foreign body slips from between the jaws of the forceps and is thus instead of being extracted driven further in. The classic treatment by injections is too often neglected. It is not, it must be admitted, invariably successful, even when employed from the outset, but it has one great advantage, namely, that it is without danger, whereas serious accidents and even death have resulted from the unskilful use of instruments.

M. Verneuil stated that when a child having a foreign body in the ear is brought to the hospital, before any attempt at extraction has been made, there is rarely any difficulty in removing the foreign body. If, however, such attempts have been made, chloroform should be employed. If the tissues have been irritated, if the membrana tympani has been torn, the application of an instrument, however gently, causes more or less severe pain and provokes movements so violent that the auditory organs are in danger of being seriously injured. Chloroform has this great advantage, that by rendering the patient insensible to pain, it prevents violent motion. M. Verneuil stated that he has seen children brought to the hospital by physicians in attendance on them who were firmly convinced of the presence of a foreign body in the meatus externus, and who, under this conviction, had introduced instruments and made many attempts at extraction, with the effect of lacerating the tissues, tearing the membrana tympani, and even laying bare the petrous bone, adducing as proof of the presence of a foreign body the sound given by the instrument on striking the bone thus uncovered. M. Verneuil succeeded with difficulty in convincing them of their error. Having administered chloroform to the unfortunate child he then demonstrated that the body sought for existed only in imagination, and that the only reality was the injury to the child. According to M. Verneuil the methods of treatment should be employed in the following order:—Firstly injections of water, suitably practised; secondly, if the foreign body resist chloroform to be administered without hesitation, as instruments may then be employed without danger to the patient, as, for instance, a forceps or scoop to seize or draw out the foreign body.

M. Farabeuf remarked that on one occasion he successfully extracted with the forceps a grain of barley from the ear of a child.

M. Despres summed up by declaring that the members of the Surgical Society who have taken part in this debate are unanimous in their opinion as to the superiority and expediency of treatment by injections of warm water to all other methods of treatment for extracting foreign bodies from the auditory canal. They consider that in all such cases, save that of the presence of a haricot bean, an essentially hygrometric body, injections of water should be employed before trying any other method of extraction, and that not to do so constitutes a serious error in surgical practice.

#### TREATMENT OF PARALYSIS OF THE ACCOMMODATING MUSCLE (VERT).

In case of paralysis of the ciliary muscle (accommodating muscle) and of the sphincter of the pupil, the author recommends repeated instillations of a collyrium of neutral sulphate of eserine and fomentations of aromatic spirits. If needed, electricity may be employed, applied locally, as may also subcutaneous injections of strychnine. If these measures fail there is no recourse left but palliative treatment, that is to say the use of convex glasses adapted to the degree of paralysis. Generally, it is only through repeated trials that the defect of refraction can be exactly corrected.

THE Army Medical Officers who have taken part in the recent Afghan war have, we understand, expressed a desire to commemorate the services of the Medical Department in the various expeditions in Afghanistan by some permanent memorial. The *Globe* says it has been decided that this is to take the shape of a piece of plate for the Officers' Mess, Army Medical Department, Aldershot.

## Special.

### INTERNATIONAL MEDICAL CONGRESS, LONDON.

THE following programme has just been decided on officially in the Section for Military Surgery and Medicine, to be held August 2nd to 9th, 1881.—President: Surgeon-General Professor Lengmore. C.B. Vice-Presidents: Sir William Muir, M.D., K.C.B., Director-General Army Medical Department; Surgeon-General Sir Joseph Fayrer, K.C.S.I., M.D., LL.D., F.R.S, India Office; Dr. J. W. Reid, Director-General Medical Department of Navy. Secretaries: Dr. W. H. Lloyd, Fleet Surgeon R.N.; Surgeon-Major Sandford Moore, Aldershot; Surgeon A. B. R. Myers, Coldstream Guards.

*Proposed List of Subjects for Discussion, subject to Revision before 31st December, 1880:—*

1. By what arrangements can the practical difficulties in the way of employing antiseptic surgery (Listerism) in the treatment of wounds inflicted in the field in time of war be most readily overcome? [The discussion to include (a) the system on which the treatment can be most efficiently carried out; and (b) the fittest material means to be employed in it, under the circumstances in which armies are placed while on active service.]

2. To what extent, and in what special directions, has conservative surgery advanced in field practice, as shown by statistical results of the treatment adopted for gunshot wounds during the wars of the last ten years? And what indications have been afforded, if any, by the experience gained during this period for making further advances in the conservative treatment of such injuries?

3. What are the most reliable and, at the same time, practicable means of immobilising the parts involved in gunshot fractures of the spine, pelvis, and femur in field practice?

4. On improvements in field hospital and transport equipment, for use with armies moving in uncivilised or partially civilised countries, suggested by the experience gained during the recent military operations by British troops in South Africa.

5. On the prevalence and prevention of typhoid fever among young soldiers in India.

The president and secretaries will feel obliged by your sending a reply, stating if it is your intention to be present at the Congress, and if you have any suggestion as to subjects for discussion.

All communications regarding Section 14 should be addressed to Surgeon A. B. R. Myers, Coldstream Guards Hospital, Vincent Square, London, S.W.

### INTERNATIONAL EXHIBITION OF HYGIENE.

On Wednesday, Dec. 29th, at a meeting of the Committee of the Parkes Museum of Hygiene, Mr. Geo. Godwin, F.R.S., in the chair, a proposal was made to hold an International Exhibition in 1881. After a long discussion, in which Dr. G. V. Poore, Prof. Corfield, Mr. E. C. Robins, Mr. Rogers Field, Dr. Gowers, and Mr. Mark H. Judge took part, the following resolution was unanimously passed:—

“That Her Majesty’s Commissioners of 1851 having expressed to the Committee of the Parkes Museum of Hygiene their willingness to provide space at South Kensington for an Exhibition of Sanitary Appliances and the Industries connected with Medicine on the occasion of the International Medical Congress in 1881, it is desirable that the Committee should organise such an Exhibition provided that a sufficient guarantee fund be obtained.”

Those desirous of assisting the Committee in the work they have thus entered upon are requested to send their names to the Treasurer of the Museum, Professor Berkeley Hill.

### ST. THOMAS’S HOME.

THE Governors of St. Thomas’s Hospital, acting under authority of the Charity Commissioners, announce that they are prepared to receive into St. Thomas’s Home persons of the upper and middle classes who are able and willing to pay the benefits of medical attendance and nursing therein—benefits which have hitherto been confined to the poor alone. In order to carry this into effect the Governors have appropriated two wards in the Hospital which are distinct from the other or ordinary wards and are situated in one of the end blocks, and are approached by a separate gate and entrance. These two wards have been fitted up and furnished expressly for the purpose of accommodating patients of the classes above mentioned. Each patient will have a separate sleeping compartment, curtained off with thick impervious linen curtains from the others, and each compartment is lighted by a large window, and is approximately and comfortably furnished. There are warm and cold baths, and every requisite of the best description. As the hospital is situate in a large garden facing the River Thames and the Albert Embankment, and is also in close contiguity to Lambeth Palace, the occupants of the home will have the advantage of these open spaces and good air. The patients in the Home will be under the professional charge of a resident officer of superior medical and surgical qualifications, and of him exclusively, for their ordinary treatment, but every patient will have the option of employing, at his or her expense, any legally qualified medical practitioner in consultation with such resident medical officer. The minimum charge for each patient will be 8s. a day, but the Governors reserve to themselves the right to take into consideration the state, position in life, and circumstances of each patient, and the nature of the case, and to require a higher daily charge when necessary.

## Transactions of Societies.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 1, 1880.

Dr. W. S. PLAYFAIR, President, in the Chair.

#### PYGOPAGI TWINS.

THE PRESIDENT exhibited the conjoined twins, Rozalie and Josetta Blazet, born in Bohemia in January, 1878. They belonged to the second of the four classes into which he had divided cases of double monstrosities, viz., “Two nearly separate bodies united back and back by the sacrum and lower part of the spinal column.” There is a broad and firm bony junction at the lower part of the lumbar region, the pelvis being obviously completely fused. There are two labia majora, a common urethral and anal aperture, and a double vaginal orifice, the septum separating the two canals being apparent. Sensation is quite distinct, except where the pelvis are joined. Delivery was very easy, the mother not having been more than a quarter of an hour in labour. The head and shoulders of one twin were born first. The midwife now used strong traction, and thus delivered the feet of both children, the head and shoulders of the second twin passing last. This was the usual mechanism of delivery in such cases. Delivery is probably easier in this class of monstrosity, and hence, although this class is comparatively rare, a large proportion of the living

monsters have been of this type, as for example, the Hungarian twins, Judith and Helen, and the so-called two-headed nightingale, Milly-Christine, exhibited some years ago in this country, and still living.

#### ECZEMA OF THE NIPPLE IN PREGNANCY.

Dr. THOMAS CHAMBERS exhibited a drawing from a case of eczema of the nipple in both breasts in a woman, æt. 21, married six months, and five months advanced in her first pregnancy. The disease commenced when she was two months pregnant. After confinement it began to disappear, and no trace remained after six weeks. In two cases of long standing, apart from pregnancy, under his care, the eczema had been cured by treatment directed to the uterus, uterine symptoms having also existed.

#### FOLLICULAR HYPERTROPHY OF THE CERVIX.

Dr. HERMAN showed a specimen of pedunculated growth from the cervix uteri, removed by the écraseur at the fifth month of pregnancy. No ill-result followed the operation, and the patient went the full term. When she came for treatment she had been suffering from hemorrhoids for three or four months, and for about a week the tumour had been outside the vulva. The tumour measured  $1\frac{1}{2}$  by  $\frac{1}{2}$  by  $\frac{1}{2}$  inch. It consisted of the normal tissues of the cervix, and contained glandular cavities, from the size of a marble downwards, lined with cylindrical ciliated epithelium.

#### Dr. PRIESTLEY ON

#### THE INDUCTION OF ABORTION AS A THERAPEUTIC MEASURE.

The author considered that the indications for the induction of abortion, as distinct from the induction of premature labour, had never been laid down with sufficient precision in this country. It was usual to say that each case must be judged on its merits, and this lack of rules might unfortunately lead to serious abuse. Examples had repeatedly come within his knowledge where abortion had been provoked for reasons which seemed to him quite inadequate. Though the medical man was no doubt acting in entire good faith in these cases, it would have been very difficult to sustain his action in a court of law. For instance, in one case abortion was induced at the fourth or fifth month on account of a bad rupture of the perinæum at the last confinement. In a succeeding pregnancy a sound was introduced with a similar object at the end of a month; this, however, had no effect, and she went to full term, and had an easy and natural labour. In a second instance an attempt was made to induce abortion at the second month because the patient had aborted not long before, and it was feared that pregnancy had recurred too speedily, while a much-desired journey would have to be postponed if miscarriage recurred at the same period as before. Fortunately, the attempt failed, and the patient went to her full term. It was often necessary to remind wives and mothers that even spontaneous abortion is often more damaging to health than natural parturition, more frequently lays the foundation of disease, and, if repeated, abridges the period of youth and comeliness. These risks were necessarily greater if abortion was induced. The reasons which may be adduced as justifying the induction of abortion are the following:—(1) Pelvic deformity so great as to preclude the birth of a viable child. (2) Narrowing of genital canal by tumours, cicatrices, or cancer so as to prevent the passage of a viable child. Great care was here necessary not to over-estimate the amount of obstruction. If a series of cases of Casarian section with fair success should occur, the reasons for inducing abortions in such instances would be undermined. In cases of cancer there was fair ground for this operation, since the woman had but a short time to live in any case. (3) In obstinate vomiting in pregnancy, when all other expedients are fruitless, and a fatal result is anticipated if relief cannot be afforded. (4) In eclampsia abortion should only be induced as a last resort to save life. (5) In irreducible retroversion or retroflexion of the gravid uterus, but only when life is seriously threatened, not merely because the displacement is irreducible. (6) In severe hæmorrhage. (7) In certain other diseases where the complication of pregnancy is undoubtedly endangering life. The responsibility of inducing abortion should never be undertaken without a consultation of two or more medical men, and M. Tarnier had even suggested that a legal declaration should be made to the public prosecutor in every case. He would lay it down that the induction of abortion is only legitimate when the life of the

mother is so imperilled by the continuance of pregnancy that emptying the uterus presents itself as the only alternative to save the mother. In insanity, chorea, and the like, the proper treatment was probably to treat the morbid conditions, and leave the pregnancy to take care of itself.

The PRESIDENT said that it was somewhat curious that this important subject had not previously been brought under the notice of the Society. In one respect we could congratulate ourselves, namely, that, so far as his experience went, the induction of criminal abortion was by no means so prevalent as in other countries.

Dr. BARNES agreed as to the importance of never undertaking the operation without a consultation. Two men would not be likely to conspire in error or crime, and the consultation would be an effective safeguard against censure. He repudiated the proposition of Simpson that it might be right to deny to a woman the privileges of repeated delivery by craniotomy. She was not a free agent. In albuminuria with retinal hæmorrhage he thought that the motive for induction was adequate, and in the vomiting of pregnancy he could not assent to the author's indications for the operation. If we waited for grumous vomiting and the other extreme symptoms we should wait too late. He also emphatically dissented from the author's proposition that in such cases as insanity we should treat the disease and let the pregnancy take care of itself. The disease depended upon the pregnancy.

Dr. HICKINBOTHAM asked what the author's experience was as to the danger of inducing abortion in the early months of pregnancy?

Dr. MURRAY thought that in the case of *early* conception, preceded by secondary, or even tertiary, syphilis in the husband, it might be a question whether early induction of abortion might not prevent the poison being so thoroughly absorbed by the wife.

Dr. GRAILY HEWITT agreed in the main with the principles laid down by the author. He mentioned a case in which it was feared that reason would give way, where it was evident that the condition depended on want of food, and attention to this point caused amelioration of symptoms.

Dr. ROPER had never met with a case either of disease consequent upon pregnancy, or seriously complicated by pregnancy, in which he thought it necessary to induce abortion, and he had never seen a patient die in any such case. He believed that criminal abortion was not uncommon.

Dr. EDIS said that many an obstinate case of vomiting in pregnancy for which abortion was regarded as the only cure might be relieved by attending to the condition of the cervix. In irreducible retroflexion pregnancy might go on to term. In urgent cases of heart disease he thought it might be essential to empty the uterus.

Dr. CLEVELAND said that it was not uncommon for a husband to request the medical attendant to induce abortion on the alleged ground that his wife could never survive such a pregnancy or delivery as the last. He mentioned several such cases in which induction of premature labour had proved sufficient, or the patient had gone to full term.

Dr. MALINS thought that the production of abortion was not in some instances an easy matter, even in skilled hands, nor always without risk to the patient. In some acute cases it even substituted a greater evil. Thus he had seen septic symptoms follow when active kidney mischief was present.

Dr. HAYES thought that Dr. Priestley had done good service in pointing out the legitimacy of the operation in certain cases. He asked his opinion as to the best method. He would himself prefer preliminary dilatation by sea-tangle tents.

Dr. PRIESTLEY, in reply, said that it was no part of his purpose to extend his paper to the methods of inducing abortion. In some cases it was only too easy; in others nothing short of fully dilating the cervix by sponge tents and removing the ovum sufficed. He believed the operation not free from risk even when all due care was exercised. He feared that the necessity for it was more frequent than Dr. Roper and Dr. Edis would seem to indicate, but was glad to enlist these authorities on the conservative side. He thought that there was force in the statement of Dr. Barnes that one might in some cases wait too long for the safety of the patient.

## SURGICAL SOCIETY OF IRELAND.

SESSION 1880-81.

The opening meeting of the Surgical Society of Ireland for the Session 1880-81 was held in the Albert Hall, Royal College of Surgeons on Friday evening, November 26th, Dr. M'CINTOCK, President of the College, in the chair.

Mr. TUFNELL, Hon. Sec., read the minutes of the previous meeting, which were signed.

## THE PRESIDENT'S ADDRESS.

The PRESIDENT of the College delivered the Inaugural Address, which will be found in our issue of December 8th on page 472.

Mr. KENDAL FRANKS read a communication on

ACUTE LARYNGITIS WHILST CONVALESCING FROM SMALL-POX. which will be found on page 4.

Dr. HENRY KENNEDY thought the meeting should feel very much indebted to Mr. Franks for his interesting case. Some might be inclined to question how far the state of the larynx had any connection with the previous small-pox. But passing that by, laryngitis, as occurring in small-pox, had repeatedly come under his notice; and he had also had frequent opportunities of examining the bodies after death. He himself had never seen anything of the effusion of lymph. The common appearance was a few pustules affecting the rima, and a large amount of œdema of the glottis and of the parts about it. He was able to confirm Mr. Franks's observations as to the frequency of the latency of this state, and, if unprepared for it, it is apt to be overlooked. The general state of the system being so blunted, the disease would go on to a fatal termination with exceedingly limited symptoms. So much had the President lowered medicine he was afraid to say anything in reference to it, but he could say he had seen repeated cases of the disease averted by medical treatment. On the slightest appearance of hoarseness, or loss of voice, or any of those symptoms that usher in the state of the larynx, two or three leeches should be applied. He had sometimes himself applied a single leech with good effect. The existence of spasm should never be overlooked. Independently of the œdema, there was frequent tendency to spasm. The tendency of the disease was to show itself in spasmodic attacks which might prove fatal. With that idea in mind it was very useful to administer anodynes, e.g. 5-gr. doses of Dover's powder. Thus he would like to have something said in favour of medicine.

## THIRTY-THREE VESICAL CALCULI IN THE BLADDER.

Mr. H. G. CROLY exhibited thirty-three perfectly formed calculi removed by him from the bladder of a man, æt. 55, admitted last July into the City of Dublin Hospital under his care, with all the symptoms of stone, from which he had been suffering for about five years. The patient had frequent attacks of retention of urine, and required the use of the catheter. He passed quantities of blood from time to time from the bladder. Having been sounded by Dr. Loverock, of the county of Cavan (a former apprentice of Mr. Croly's), he was sent up for operation. With Sir Henry Thompson's sound, Mr. Croly had not much difficulty in hitting a stone. Seizing a stone in the lithotrite, he hit with it stones in different directions in the bladder. It was a case of multiple calculi, and unsuitable for crushing; so he removed them by the ordinary lateral method. There was not much trouble in getting out the calculi, except the large stone, most of them having been got out by the introduction of the finger and the gorget, while the large stone required a little enlargement of the neck of the bladder. The operation occupied fifteen minutes. All the stones taken together weighed only 4 ounces. The largest weighed 2, and all the rest 2. Of these calculi, the smallest had just as perfect facets as the largest. There were thirty-three distinct stones. Dr. Abraham had made a section of one. The calculi seemed hollowed out in a peculiar way. They were made up, as one would naturally conclude from their appearance, of phosphates; but Dr. Abraham had informed him that there was also a small portion of oxalate of lime in the interior of the stone. The patient was now very fat, and Mr. Croly had hoped to produce his photograph, as being a remarkable man. He would publish the case.

## PORTION OF THE LOWER JAW WITH A LARGE TUMOUR ATTACHED.

Dr. KILGARIFF exhibited a considerable portion of the lower

jaw with a large tumour attached which he had removed in the Mater Misericordiarum Hospital on the previous day from a male patient, æt. about 85. From inquiries, he learned that the tumour had first made its appearance about three years ago. It was then very small, and was situated in the centre of the horizontal ramus of the jaw over the left side. Its growth was very slow, nor did it cause much annoyance to the patient, as not being the site of pain, until about six months ago, when its growth became suddenly energetic, and so continued from that date to the day of his admission into hospital. The large tumour caused hideous deformity of the face, and, owing to its position, it interfered materially with the movements of the lower jaw. On examination, he found that there was a tumour intimately adherent to the bone, extending from the outer incisor tooth on the left side, running across the body of the bone, up along the body of the ramus, and ceasing about the junction of the lower and middle third of the ascending ramus. There were no glands engaged. He removed, for microscopic observation, a small portion of the tumour, and submitted it with that object to his colleague Mr. Coppinger. On examination, it proved to be a hard fibroma. Having consulted with his colleagues, they approved of his removing the tumour with the jaw, which he did. The weight of the tumour, including the attached portion of bone, was precisely 10 ounces.

## CONGENITAL TUMOUR OF THE PHARYNX.

Dr. BARTON, in exhibiting a congenital tumour of the pharynx, said the specimen was something of a pathological curiosity, as the Society would be in a position to judge on his detailing the facts. Margaret M'Clelland, æt. 22, a domestic servant, was brought by her mistress to me on the 19th of July last, complaining of difficulty in swallowing, and a sense of pain and fulness in her ears and head, which she attributed to a growth in her throat, which she stated had much increased lately. Upon opening the mouth widely and depressing the tongue, a tumour was seen occupying the pharynx about the size of the last joint of the thumb of an adult hand; it was white, or skin colour, and contrasted strongly with the red colour of the velum and fauces. Upon introducing my finger, I felt that the tumour was pendulous and narrower above than when it appeared behind the velum; it seemed to hang from the basilar process of the occipital bone, or roof of the pharynx. The girl stated that, as far as she knew, it had always been there, but had not caused her any annoyance until lately, when it began to increase in size. I admitted her to hospital, and next morning proceeded to remove the tumour. The mouth being held well open, I found no difficulty in placing the wire of an écraseur round the base or narrowest part of the tumour; I then seized the lower part of the growth with a vulsellum and gradually tightened the wire, when, however, I was met with a difficulty, the structure of the growth proved so tough and unyielding that the wire broke before it had done more than tightly constrict the pedicle. Withdrawing the écraseur, but leaving the wire tight round the pedicle, I cut off the growth with a blunt-pointed curved scissors, and next day removed the loop of wire. The patient left the hospital in three days afterwards quite relieved of the symptoms she had complained of, and I have since heard that she continues quite well. The appearance presented by this tumour was very remarkable, and quite different from anything I had previously seen. The growth nearly filled the span between the pillars of the fauces, and contrasted strongly both in colour and surface with the velum under which it appeared, and the fauces on either side of it. The sensation given to the finger when passed round it, was that of a soft skin covered tumour, and contrasted markedly in this respect also, with the mucous surface around it. After the amputation of the growth nothing could be seen upon looking into the mouth as the tumour had been cut off above the velum, but the finger, when introduced, could readily distinguish the cut projecting base of the tumour above and on left side, and trace it upwards as far as the posterior nares, but could not make out more particularly its point of origin. The passage of the nose was free. Dr. Barton added that, on a rough immediate microscopic examination of the tumour, the suggestion at once arose that it was of curious and unusual growth, inasmuch as it was distinctly covered with skin and hair bulbs; it was fatty, and where the scissors had nipped it across at its base the appearance of a cartilage was presented. On examining the patient within the last few days, he noticed a little white patch still remaining on the upper and left side of the pharynx, from which the tumour had been removed. What the nature of the patch was he was unable to state, but it

appeared to correspond with the edge of the left Eustachian tube. In medical literature he had not been able to find an analogous growth—namely, a skin-covered fatty tumour growing in the same place. Dr. Abraham had carefully examined it, and would report the result.

Dr. ABRAHAM said he had made a careful examination, microscopically, of the structure, and would report the results.

#### OVARIAN TUMOUR.

Mr. H. G. CROLY exhibited an ovarian tumour which he removed on the 3rd of November last from a patient, *set. 44*, who had been suffering about six months, and was admitted into hospital on the 19th of October. She came under his father's observation, and he had diagnosed the tumour as uni-ocular ovarian, at all events, made up of one cyst. The ordinary operation of ovariectomy was performed, and the patient left the hospital for her residence a fortnight afterwards. The operation was carried out strictly in accordance with antiseptic rules, and there was primary union. Three times only did the house-surgeon dress the case, and he stated that from first to last there was not as much pus as would go on the point of a needle.

#### EXCISED ULNA.

Mr. H. G. CROLY exhibited also the ulna of a patient excised by him on the previous Tuesday. Almost the entire ulna was diseased, but none of the rest of the arm. It was fractured in the centre. He excised the ulna from the wrist to a little below the elbow. Should the case go on well, it would be of great advantage to the patient to have one of the bones of the forearm.

The Society then adjourned.

### SOCIETY OF METROPOLITAN MEDICAL OFFICERS OF HEALTH, DUBLIN.

A MEETING of the above Society was held at the Royal College of Surgeons, Ireland, on Wednesday, Dec. 8, 1880, at 4.30 p.m.

*Present.*—C. A. Cameron, M.D., in the chair, also Drs. Hedley, T. W. Moore, Pollock, Delahoyde, Ryan, Strahan, W. D. White, Jacob, and Purcell, Hon. Sec.

After the reading and signing of the minutes of the previous meeting, and the transaction of some routine business, the subject for discussion, *viz.*—

#### THE PROPOSED LEGISLATION ON THE NOTIFICATION OF INFECTIOUS DISEASES IN DUBLIN

was introduced by Dr. J. W. Moore, who gave a sketch of the proposed legislation respecting compulsory notification of acute infectious diseases. He instanced the examples of Leicester and Edinburgh, in which considerable opposition to the system of notification by the medical attendant was offered by the medical profession in the first instance, while no objection had been made to the working of the Acts since they came into operation. Dr. Moore drew attention to the fact that the Town Council of Edinburgh and Dublin were in favour of compulsory notification by the medical attendant, which he submitted was a sufficient answer to the argument that this system would be an infringement of the confidential relations between the physician and the head of the house. He thought that the dual system of notifying—both by the physician and the person in charge of the patient—was that most likely to succeed in checking the spread of epidemics. He objected to certain of the provisions which were in force in some large British towns, but was confident that in a very short time the public at large would recognise the advantages to the health of the community which would accrue from early intimation of the outbreak of infectious diseases being given to the sanitary authorities. In conclusion, Dr. Moore urged upon the Society the prudence of adopting some scheme which would secure at once the safety of the community and the honour and dignity of the profession of medicine.

Dr. CAMERON considered that there was all but the most perfect unanimity amongst medical men as to the imperative necessity of rendering compulsory the notification of cases of infectious disease to the sanitary authorities. The objections urged by medical men against the duty being imposed upon them appeared to rest chiefly upon the assumption that by doing so they would violate a professional confidence reposed in them. It was urged that there was the same confidential relation between the physician and his patient as those between the priest and his penitent and the solicitor and his client. No

doubt there were occasions when it would be highly improper for a medical man to publish or to communicate to any one in private the diseases with which any of his patients were afflicted; but when a case of small-pox or typhus fever occurred in, say a crowded house, or indeed under any circumstances, it was absurd to regard such an occurrence as an event to be kept under any circumstances as a secret. The patient could not be properly tended if his illness was to be kept a secret. Besides, there was nothing to be gained to the general public by the publication of the sins of penitents or the revelations of clients to their solicitors, whereas, it was of the utmost importance to the public that existence of cases of contagious diseases should be speedily known. If the law made it incumbent on the medical man to report all cases of infectious disease to the authorities, no particular medical man would be a loser thereby, whereas, at present, the poor-law medical officers are frequently not consulted because it is known that they give prompt notice in such cases, though other practitioners do not as a rule do so. Some medical men whose practice lies amongst the middle and upper classes of society, think that the families of their patients would feel offended if the existence of contagious disease in their houses were reported by their medical attendant. This is a fallacious notion. Supposing such a report made, what can the sanitary authority do? They cannot remove the patient from his home because the proper means for curing him are sure to be present. They can only offer assistance in the way of disinfecting bedding, clothing, or rooms. As a matter of fact, the well-to-do people, in whose houses infectious diseases occur, are always anxious to be in communication with the sanitary authorities. So frequent are the applications to me for information as to how to act in such cases that he (Dr. Cameron) prepared a little pamphlet giving the information usually required. On the other hand, when a serious zymotic disease appears in a tenemental dwelling in which, as is often the case, there may be four families upon the one floor, surely the importance of prompt information is obvious. Now, will the poor people in such dwellings give this information? I am certain that in the majority of cases they will not do so at all, or until it is too late to be useful. If compulsory notification of contagious disease is to be usefully carried out it must be by the physicians. Dr. Cameron concluded by reading extracts from a letter from the chief Medical Officer of the Hague which stated that in Holland compulsory notification of contagious diseases had been for some time in force, that it worked well, that the physicians gave the notice, and that the existence of such diseases was placarded upon the infected houses by the local authorities. In several of the States of the United States of America a similar system was in force.

Several other members having spoken, the meeting adjourned.

## The Mineral Waters of Europe.

### ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, &c.

WITH

### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.,  
Lecturer on *Materia Medica* and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

(Continued from page 525.)

#### *Therapeutical Uses of Purgative or Bitter Waters.*

What, then, are the effects produced by a series of doses of saline aperients such as we find in these bitter waters? Much depends on the doses, the circumstances under which they are taken, and the condition of the patient. We can so regulate the administration as to obtain the mildest laxative effect, or we may push it in drastic doses until it proves dangerous. Some patients obtain from a small dose each morning a comfortable

evacuation without irritation ; others find that a degree of diarrhœa is always produced after a few doses. The fact is these salts are unquestionably irritants, and it is natural to expect that continuous doses will set up gastric and intestinal catarrh. This is their ordinary aperient action. They pass rapidly through the stomach into the intestines on which their chief action is expended, and are removed for the most part with the fœces. Taken warm, properly diluted, they scarcely affect the stomach at all, but large doses are apt to disturb it. A good deal of mucus and albumen is removed in the artificial diarrhœa set up, besides which biliary matters and digestive products are found in the excretions. Thus, it is clear, the bowels are more rapidly emptied, and the aliment may be so hurried through as to prevent the proper absorption of the nutritive parts. In this way assimilation is interfered with. At the same time tissue metamorphosis is increased. All this accounts for the uniform experience that courses of bitter waters cause loss of body weight, and particularly decrease the fat. If pushed too far, they may no doubt produce extreme emaciation, but much depends on the digestion. If the food supply is sufficient to make up for the extra waste and the waters do not unduly irritate, there may be no loss of weight so long as the digestion is good, the matter removed being replaced by fresh nutriment. Thus it will be seen that the regulation of the diet is of extreme importance if we would obtain from these waters the greatest benefit with the least disadvantage. As to other systems, only a small proportion of the sulphates is absorbed. Some of the sulphuric acid escapes through the kidneys, but the urine contains less nitrogen, though this is probably only because a larger amount of that element is being carried away through the bowels. On muscular tissue magnesia and soda have little effect compared with potash, and the refrigerant action of the salts can scarcely be due to their effect on the heart. The soda salt, if not the magnesian, also diminishes the coagulability of the blood. But with regard to the less marked powers of the waters, the chloride of sodium and other salts found in most of the purgative waters are of as much consequence as the sulphates.

From the preceding considerations it may be inferred that these waters may be used to unload the bowels and to quicken the passage of materials through the intestines ; to promote tissue changes, and to remove superfluous fat ; to relieve the portal system and to deplete by causing increased serous flow, and in the same way to promote absorption and elimination. The extent to which either or all of these objects may be obtained differs with the individual waters, and the mode in which the course is regulated. The special conditions to which they are adapted will be best considered in reference to the particular waters. These we will now consider in the order in which their chemical qualities have previously been discussed.

*Friedrichshall Water.*—This is an excellent aperient water, of medium strength, containing both soda and magnesia sulphates, modified by no inconsiderable amount of chloride of sodium. The remarkable fact discovered by our chemical colleague that the bottled water contains much more of the salts than previous analyses indicated goes far to account for the efficiency of the purgative action. It will also help us to dissipate the error so sedulously propagated that mineral waters possess a mysterious power of increasing the action of their ingredients. Even Sir H. Thompson, in the lecture quoted in our last report, has adopted this unfounded notion. Having calculated that his dose of Friedrichshall contains only twenty-five grains of each of the sulphates, he says that quantity "taken in any combination out of a druggist's drawer would have no appreciable action." This is only a forcible way of putting a statement often made about mineral waters, and which we do not hesitate to pronounce erroneous. We have no difficulty whatever in getting a marked effect from such doses of these drugs. If Sir H. Thompson will take these drugs in the same state and under the same circumstances as he gives them in the waters he will soon modify his opinion. Of course, to send them in an ounce draught with a little flavouring is not the acme of medical or pharmaceutical skill. This much, taking the analysis as in Liebig's time ; but in future it must be remembered that the water now imported contains a third more salts. See analysis in previous report. Friedrichshall is, then, a very good household aperient, of which a dose may be taken when required with as little inconvenience as any ordinary saline purgative. But the water may still further be utilised for subjecting patients to continuous doses in the manner already indicated. It is more active than Carlsbad, and for that reason more convenient for this purpose, but it should be taken in the same way and a similar *regime* enforced.

*Dose*—From a quarter to half a tumblerful for adults according to effect desired. For children less in proportion to age. It should be taken an hour before breakfast. The best plan is to add enough hot water to it to make it warm, drink it in this state, and follow it shortly with a cup of weak tea or coffee. Warm milk or broth may in some cases be more advisable. Continuous doses generally require to be gradually diminished, since, as with most remedies of this class, their effect is more easily produced after a few repetitions.

In well-nourished or fat patients, subjects of "biliousness," in plethoric individuals, in hepatic derangements, or torpor of the abdominal viscera or sluggish portal circulation, in lithiasis, in many gouty and some rheumatic, in a few hæmorrhoidal subjects a course of this bitter water is very useful provided it is accompanied by a well-regulated diet and regimen.

(To be continued.)

## FOG AND PHYSIC.

WHATEVER may be the amount of ill ascribable to the fogs, which in recent years have been painfully familiar accompaniments of the winter season, one good at least has arisen out of them. The interest excited by discussion of the various means suggested for remedying the nuisance to which we have been periodically subjected, has been so considerable and general that many practical minds have been drawn to a consideration of the method available for abating the mischief in the future. The almost unparalleled rapidity with which the death-rate of London and other large towns grew last year, until it assumed the most frightful proportions, excited a keen desire in the ranks of sanitarians to effect something towards a reduction of the hugely disproportionate number of fatalities from bronchitic and lung affections. At the present time, therefore, we are in a position to form some reliable estimate of the probable value of these preventive measures, through the action of which we may hope for a reduction of the evil commonly present during the fog season. How much is to be expected in this direction may be gathered from an inspection of the death register for the winter of 1879-80. In a paper prepared by Dr. Arthur Mitchell, the influence exerted over the mortality of London by the memorable fog which continued from November, 1879, to February in the year just past, is exhibited the death-rate of the metropolis being shown to have grown from 1,754 to 3,376, which number of deaths was registered in one week. In other large towns no such huge increase was noted, although a certain amount of illnesses terminating in death could be attributed in excess to the prevalence of fogs. It is significant

that asthma is the disease to which, in greatest numbers, deaths were attributed during the prevalence of the great fog in London, and at the present time the experience of physicians points to the same affection as the most potent agent in swelling the list of casualties in their practice. Moreover, pneumonia, bronchitis, and pleurisy, are chief among the ailments whose ratio is highly increased during the foggy period of an English winter, bronchitis especially rising to an unprecedented height. It is well, in view of this fact, and the constant possibility that the history of 1880 may be at any time a repetition of that of the previous year, to consider the details already presented to us in explanation of the occurrences now familiar to all our readers. There seems to be no question that the principal evil to be dreaded in connection with dense fogs is less due to the mere vaporous atmosphere than to the precipitated impurities with which it is charged. Injurious though it may be, the former presents elements of danger against which reasonable precautions will avail; but of the latter it may be said that hardly any remedy is found to avail against it. Compounded of soot impregnated with gaseous acids, ammonium sulphide, and numerous other highly irritating impurities, a covering is formed for the aqueous vesicles of which the fog cloud primarily consists, and it is easy to see how the respiration of such an atmosphere will affect the lungs of the one breathing it. Even where no predisposition to disease exists there may well be created a tendency to contract it under conditions so inimical to healthy breathing; and hence it can be understood that the mortality returns during the prevalence of fog are largely swelled by deaths from lung affections. In certain situations the danger arising from this source is further enhanced by the existence of manufacturers in their neighbourhood, the emanations from which largely multiply the probabilities of danger to life. In all these the conditions of age, constitution, &c., are to be considered in weighing the consequences to be anticipated, but no calculation is sufficiently favourable to remove the imperative necessity for an immediate remedy of so much of the evil as admits of abatement. The problem this presents is in process of solution, and we may confidently hope that ere very long some means will have been adopted to rid the inhabitants of cities of the incubus they labour under in the form of fogs. Whether it be by an improvement in the fire-grate construction of private houses, and of factories, by which the evolution of smoke shall be restrained within the narrow limits, or by the introduction of a system of heating to obviate the employment of smoke-producing fuel, the immediate results will be the same, viz., relief from one of the most pressing burdens that have attended the civilisation of modern times. But, with the removal of the cause the effect will not by any means be entirely done away with also. We must expect to witness, even for more than one generation forward, the ill-consequences of deleterious action on the systems of those who have been submitted to its influence. Against this the medical practitioner of the present should direct his powers of prevention; he will not be without ever-recurring evidence of the injury done in his observations of the patients he is called on to examine, and both by warning and treatment to obstruct the progress of any destruction careful scrutiny may assure him of. The ten-

dency of modern medicine, and the assistance it derives from sanitarians and hygeists, is all in the direction of prevention, and in securing the advance of this mode of treatment we are aiding on the progress of improvement. The reduction of diseases consequent on the initiation of reform in domestic arrangements which permit of atmospheric pollution is a step a-head, and a step, too, we may well expect that we shall very soon take.

#### COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES IN DUBLIN.

WE publish to-day a report by the Superintendent Medical Officer of Health for Dublin in which he strongly advocates the proposal that the duty of notification of infective disease should be imposed compulsorily on the attending physician. We also publish abstracts of speeches addressed by Dr. J. W. Moore, and by the same officer to the Society of Metropolitan Medical Officers of Health in which the same views are expressed. These pronouncements we place before our readers in a spirit of fair play, but we are not to be understood as agreeing with them or as having nothing to say *per contra*. On the contrary, we propose to revert to the subject on the earliest suitable occasion, and give our view of the matter formed upon inquiry which we are now making. There is, however, one point in the speech of the Superintendent Medical Officer of Health which claims immediate refutation. It has been persistently represented by the advocates of imposing the notifying duty on the medical attendant, that the profession is all but unanimously in favour of such proposal. This statement was made, we believe, on the authority of resolutions adopted by the College of Physicians and Surgeons and the Irish Medical Association; it was repeated by the Lord Mayor—in spite of emphatic assurances to the contrary—on the occasion of the Corporate deputation to the Chief Secretary, where he assured that minister that no opposition need be anticipated to a Bill imposing such duty on the doctor. At the meeting to which we have referred the Superintendent Health Officer considered that there was all but the most perfect unanimity amongst medical men as to the imperative necessity of rendering compulsory the notification of cases of infectious disease to the sanitary authorities. Lest such a statement should, if uncontradicted, prejudice the fair consideration of the subject, we feel it necessary to give it the most authoritative denial. The two Colleges and the Council of the Irish Medical Association have, it is true, expressed themselves in favour of compulsory notification of disease as a proper precaution against the spread of infection, but they have just as clearly and emphatically refused to approve of the proposal that the duty should be cast upon the doctor. Moreover, the opinion of a large section of the profession in Dublin has been expressed directly, for the executive committee of the Irish Medical Association has issued a circular in which the various proposals are placed side by side and the facts stated with perfect impartiality, and, in response to that circular, replies have been sent in which—we believe we may say—are, by a great majority, unfavourable to the acceptance of any such duty by the profession. Therefore, so far as the feeling of the pro-

fession is known, either directly or through its representative Colleges and the Irish Medical Association, that opinion is unequivocally adverse. We do not wish that the indisposition of medical men to accept the duty should be a final reason for refusing the propositions made, but we urge that the opinion of the profession in Dublin should be obtained in the completest form, and that then the representative organisation should debate the subject. If, this being done, it seems that the proposals are thoroughly objectionable, then we look for an earnest opposition to the proposed Bill; but if it shall appear that the objections are more than counterbalanced by the benefits to be gained, we shall in that case presume that the measure may be left to pass unopposed, subject to such modifications of detail as may suggest themselves.

#### THE LUNACY COMMISSION.

WE are glad to be able to give an emphatic contradiction to a statement recently made, as if on authority, that Dr. Nairne, the Senior Medical Commissioner in Lunacy, is about to resign his appointment. Dr. Nairne, although no longer young, is still vigorous, and has no immediate intention of retiring from an office which he has long filled with usefulness and distinction, which he continues to fill to the satisfaction of his colleagues and of the public, and to the duties of which he is likely to be fully equal for some time to come. The prediction that Dr. Nairne will, on his retirement, be succeeded by a general physician without special lunacy experience is a mere conjecture founded on the fact that Dr. Nairne was himself a general physician attached to St. George's Hospital, and had never held any asylum appointment when nominated a Lunacy Commissioner. Since the date of Dr. Nairne's appointment, however, the aspect and relations of lunacy, as a special department of medicine have changed very materially, and it is most unlikely that those who will be called on to fill up any vacancy that may occur on the medical side of the Lunacy Commission will overlook the value of a practical acquaintance with mental diseases—which are often so obscure, requiring such nice diagnostic tact—and with lunatic hospital management and hygiene. Amongst our brethren engaged in lunacy practice several might be named who would make admirable Commissioners, and who would bring to their work in that position a ripe experience and an established reputation. Of this, at any rate all those who are interested in the matter may feel assured that nothing has as yet been settled as to the qualifications of Dr. Nairne's successor, and that the topic will not even be discussed until Dr. Nairne formally intimates his wish to be relieved of the responsibilities of office. When that time arrives, and we trust and believe that it is still at some distance, the Lord Chancellor for the time being, with whom the appointment of the commissioners rests, whether acting on his own judgment, or after conference with the Chairman of the Board of Commissioners, will not probably ignore the fact that freedom from professional and special bias is represented, and liberally represented, by the legal Commissioners, and that that technical knowledge of insanity in all its bearing which is so essential to the safe conduct of the business of the Board, is only to be obtained by selecting medical commissioners who have acquired it by a prolonged study of the subject.

## Notes on Current Topics.

### Illness of the Viceroy of India.

THE following is a summary of telegrams describing the illness of Lord Ripon since last we alluded to the subject, viz. :—

Allahabad, Dec. 19th.—Lord Ripon passed a good night, and is progressing satisfactorily.

20th.—Lord Ripon passed a restless night, owing to a slight recurrence of fever. His Excellency's condition this morning is however considered satisfactory.

21st.—Lord Ripon passed a good night, and the feverish symptoms have disappeared.

22nd.—The feverish symptoms have disappeared, and Lord Ripon's convalescence is now completely established. No more bulletins respecting His Excellency's health will consequently be issued.

In a telegram dated 19th December, the Calcutta correspondent of the *Times* communicated the following particulars regarding Lord Ripon's illness, namely :—On the 11th the fever had increased, and fears were entertained that it might take a typhoid form. Surgeon-General Payne proceeded to Allahabad forthwith. No specific name has been given in the official bulletins, but it is generally believed to be a somewhat severe type of the ordinary Indian remittent fever." According to the same telegram, although there appeared no reason to apprehend danger to life, still it was considered "useless to conceal the fact that the illness was serious, and the situation such as to cause great anxiety."

In our previous allusion to the illness of the Viceroy we remarked that the telegrams of his case published from day to day indicated that he suffered from remittent fever. This has been shown to have been the case. Considering, therefore, the age and delicate physique of Lord Ripon, we should not be surprised to hear that an early return to England has been recommended to him.

### A Sad Lesson from Overwork.

An inquest was held at the Halifax Infirmary on Thursday last on the body of Joseph McCarogher McWilliams, surgeon, of Halifax, who died under the following circumstances. For some time past he has been in the habit of taking narcotics in order to procure sleep, and on more than one occasion has narrowly escaped losing his life from the effects. He has often complained of overwork (he having a large practice) and has suffered from loss of sleep and from nervousness. On Christmas Day he called in Dr. Hodgson Wright, who prescribed for him an iron tonic. He began to improve, but on Wednesday morning Dr. Wright again found him fretful and nervous, and evidently under the influence of some narcotic. Dr. Wright cautioned the servants to watch him, and to keep from him all medicines of this character. Deceased admitted having had a drachm and a-half of tincture of opium, but said this was all. At noon the same day he was found in a profoundly comatose state, and he remained unconscious up to his death, which occurred at about five o'clock the same afternoon.—The jury returned a verdict of "Death by misadventure from the effects of an overdose of opium taken for the purpose of procuring sleep."

### Hydrophobia at Wigan.

ANOTHER case of hydrophobia is reported from Lancashire, and is at present under treatment under Dr. W. Berry, Wigan. The patient, a woman, æt. 40, was bitten last August, and symptoms first showed themselves on December 30th. On December 31st the case was seen by Dr. Dolan, Halifax, in consultation with Dr. Berry, and pronounced to be hydrophobia vera. We hope shortly to publish the case in full. It is very significant that Lancashire and Yorkshire figure so largely in the mortality returns from hydrophobia.

### Cholera in Burmah.

CHOLERA is reported as being very prevalent and fatal in the villages near Prome. This place is noted for the extensive scale upon which those two Burmese delicacies, *gnappee* and oil of the heads of shrimps, are there prepared, and as the former is little else than a concoction of decomposed fish, it would appear that a somewhat zealous British official determined to take the summary process of putting a sudden stop alike to the manufacture and sale of the *gnappee*, hoping thereby to suppress the further prevalence of the epidemic. But it does not appear that the measures thus taken were followed by the looked for results. Cholera, according to the latest report received, continued to prevail, but the populace, irritated at what they considered interference with their rights to *gnappee*, entered upon demonstrations somewhat personal against the offending official, and petitioned the higher authorities against the action taken by him. So much for hasty and partially considered sanitation.

### A Wise Proceeding.

WE are informed that the authorities of the University of Durham Medical School have it in contemplation to introduce a change in the arrangements for teaching medicine in the school, which will at once commend itself as a wise proceeding. It is proposed to elect an Assistant Professor to Dr. Philipson, who is at present Lecturer on Medicine, and who will henceforth confine himself especially to the principles and practice of physic, while the new professor will devote his lectures chiefly to demonstrating the practical applications of physical instruments as an aid to clinical study. There is in this suggestion so much of radical improvement that we trust it may not be long ere it is fully carried into force. It will be essential, however, to the success of the scheme that the gentleman appointed to undertake the duties of the new office shall be in every way likely to advance the object held in view, viz., the *practical* instruction of students in the method of using instrumental aids to diagnosis. It is, therefore, satisfactory to hear that the present lecturer on physiology at Newcastle, Dr. Drummond, will in all probability assume the duty. Dr. Drummond has, so far, identified himself with the study of diagnosis, and his demonstration at the bedside of the patients under his charge at the hospital wards are marked by precision and the carefulness with which all the assistance to be derived from accurate use of instruments is taken advantage of. The recognition of a need for supplementing the ordinary lectures on medicine by practical demonstrations other than the somewhat informal ones

usually performed in the ward, is an important matter to the student, and in this instance the Durham University School is to be congratulated on the possible union of Professor Philipson and Dr. Drummond as the teachers of medicine to its students. We understand that the Council of the College has regularly adopted the proposed change, at Dr. Philipson's suggestion, and that the appointment will shortly be made to the duties of the new office.

#### A New College of Science.

THE noble institutions devoted to the teaching of science at Manchester, Birmingham, Sheffield, Leeds, and Bristol, will in all probability soon have one more added to them by the creation of an institution resembling Owens College, Manchester, at Dundee. Dr. John Baxter, of that town, intimated last week his willingness to devote the sum of one hundred and twenty-five thousand pounds to such an object, and has since supplemented the munificent offer by a further promise to give ten thousand pounds additional for the same purpose. It is hoped, that these sums going towards the cost of building, a similar amount may be raised by public subscription to serve as an endowment fund. The Scotch have never been deficient in making opportunities, where none existed, of self-improvement, and it is to be hoped that Dundee may be able to boast itself of so magnificent an educational institution as the offer of Dr. Baxter offers to it. Outside subscriptions are necessary, however, to make the prospects of an efficient college certain.

#### Cardiff Infirmary.

By the generosity of the Marquis of Bute, a new site, four acres in extent, is about to be provided for the Cardiff Infirmary. The ground required for this is estimated to be worth from £10,000 to £12,000, and will have to be purchased by the noble donor from the executors of the late Lord Bute's will. The new infirmary buildings, designed by Mr. A. P. Bell, of Manchester, will accommodate one hundred patients, but provision will be made for the extension of the wards, when necessary, to hold two hundred beds. Towards the total cost of £20,000, £13,000 has been collected or promised.

#### Soldiers' Service.

It is stated in a lay contemporary, on what appears to be good authority, that among other proposed items of "reorganisation" in the army is that of altering the present system of six years' service in the ranks and six years' in the reserve to seven in the ranks and five in the reserve. No man is to be sent to India who has not six years' service before him, and the prime inducement to non-commissioned officers to remain in the service is to take the shape of a preference over other candidates for employment in the public service.

If no soldier is to be sent to India except on these terms, it follows that all who proceed to that country will be of not more than one year's standing in the army; thus the present evils in regard to health threaten to be increased rather than diminished by the proposed change. It is also stated that it is in contemplation to take into the ranks boys—for they can hardly be called men—of inferior

physique to those enlisted under the recent regulations. Against this measure there appears this saving clause that such selection must of necessity be difficult.

#### The Army Medical Department.

THE already heavily-burthened British taxpayer will in the course of the present year have to find the liberal rates of pension to which five additional medical officers of the higher grades in their department become, by regulation entitled on being compulsorily retired, viz., Surgeon-General Kendall, from 9th instant; Deputy Surgeon-General O'Leary, 5th May; Surgeon-General Mackinnon, 21st May; Surgeon-General Shelton, 23rd October; and Surgeon-General Thompson, 13th November. It is believed also that the present Director-General will retire at the end of the financial year. On this point, however, expressions of doubt have been heard; it has been stated that a further term of office may be granted to him.

#### The Amoeboid Motions of Protoplasm.

AT the meeting of the Royal Society of Edinburgh, held on the 20th December, Dr. Haycroft read a communication on the amoeboid motions of masses of protoplasm, illustrating his theory by a simple but ingenious mechanical contrivance. An india-rubber ball, perforated with a number of small apertures was filled with coloured white of egg and immersed in a solution of sugar of about the same density as albumen. When a gentle pressure was applied the albumen was forced out in long processes, and when the pressure was released the processes at once retracted inside the ball again, probably in virtue of the viscosity and surface tension of the gelatinous matter. Thus was explained the retraction of the amoeboid processes after they had been expelled by contraction of the internal muscular structure. Dr. Haycroft's theory is not yet before us, but it seems obvious that the mechanical displacement of albumen from a perforated ball immersed in a crystallised fluid and its retraction when the pressure is removed, are altogether different things from the movements of protoplasm arising out of its inherent and spontaneous contractibility.

#### Foreign Traffic in English Girls.

SOME months ago, in reviewing a pamphlet upon this subject, issued by Mr. Dyer, of Amen Corner, we felt it necessary to express some scepticism as to his statement that the Belgian officials, and even those of our own Consulate in Brussels, were agreed, in a general combination, to pooh-pooh inquiries and assertions respecting the existence of grossly illegal, immoral, and tyrannous practices with regard to English girls forcibly abducted from their own country, and kept in durance in Belgian brothels. We thought it more likely that Mr. Dyer had been imposed upon by the statements of immoral witnesses than that official immovability could go this length. We think it now but just to Mr. Dyer and to the cause which he advocates to set ourselves right in this scepticism. Twelve persons were, by the agency of Mr. Dyer, prosecuted a fortnight since in Brussels. The technical charges were forgery (by false certificates of the births of victims to make them appear over twenty-one years, when they were

several years less), incitement to debauchery, ill-treatment, and sequestration. At the end of the second day's proceedings, eleven persons were convicted on the foregoing counts, and sentenced to various terms of imprisonment, the heaviest of which (with the exception of six years on an agent, who was not in custody) were, respectively, two years, eighteen months and a-half, eighteen months, sixteen months, thirteen months, and one year, and small fines in addition in some instances. Thus the assertions of Mr. Dyer have been fully vindicated, and we gladly lend the aid of our columns to the effort which he is making to stop this infamous traffic.

### New Forms of Artificial Tympanic Membrane.

At a recent meeting of the Paris Société de Médecine Pratique (*La France Médicale*), Dr. G. Desarenes showed some new forms of artificial membrana tympani, and demonstrated their use on a patient. One of these appliances resembled that of Toynbee, consisting of a small disc of caoutchouc mounted on a silver wire so as to allow of the disc having the same inclination as the membrane when it is placed against the remains of that structure. The second form which costs next to nothing, and may be easily made by the patients, gives equally good results. It consists of a small ball of cotton wool, on a very fine iron wire about 3 cm. long. It is made by placing a little cotton wool on a fine iron wire, and then turning the wire around. Then with scissors the wool is cut so as to make a little ball of the size desired.

After having studied the various forms of artificial membrane, Dr. Desarenes, like most aural surgeons of the present day, found that the improvement produced by their application is due, not to the closure of the perforation, but to the pressure exerted on the ossicles.

In support of this opinion he showed the Society a patient, æt. 18, who hears very well with his little cotton instrument. He presents on the right side, old caries of the petrous bone, following a scrofulous otorrhœa existing from infancy. Two years since the patient came to Dr. Desarenes' clinic; some days after having undergone trepanation of the right mastoid by M. Peau the left ear commenced to suppurate, a month since, and the membrane was extensively perforated. After several months' treatment the discharge from the right ear ceased, but as the patient has been deaf with this ear for many years, and one can with difficulty perceive the stapes, hidden by large fleshy granulations, there is not much hope for the hearing.

The left ear, not bad so long, showed loss of two-thirds of the membrane, with abundant otorrhœa, without caries of bone. Great deafness. After struggling with the otorrhœa, Dr. Desarenes put in an artificial membrane, smaller than the perforation, directing it so as to press lightly on the ossicles. The patient has used this little instrument for six months, having learnt to make it himself, and put it in each morning, first moistening it with tepid water. He removes it at night, to give the ear rest, and to use injections of warm water and camphorated spirit.

The membrane was removed before the Society and the members examined the ear. The patient heard with

great difficulty. The membrane being replaced, the patient heard and answered all questions easily. Dr. Desarenes insisted finally on the necessity of all artificial membranes having a firm stem so as to keep up the pressure on the ossicles, when the membrane was moved by the passage of air through the tubes on blowing the nose.

### The Hypodermic Administration of Quinine.

DR. JAMES J. WHITTAKER (*Med. and Surg. Rep.*, Nov. 13th, 1880) finds a solution of bromide of quinine, grs. 20, to ʒij. of water, useful in treating by this method, cases of pronounced, or marked malaria, when the condition of the digestive system is such, as to prevent the absorption of quinine taken by the mouth. He directs his chemist to put 20 grains of the drug into a test tube, and to add to it two drachms of water; the tube is then to be corked and is ready for use. When it is desired to make the injection, the mixture must be heated, either by spirit lamp or otherwise, a clear limpid fluid resulting; a portion must be then poured out into a heated tea spoon and thence taken up by means of a previously heated syringe. The puncture and injection must then be made immediately, and the fluid must be thrown not into, but below, the skin. The ordinary syringe holds half a drachm. As many as 1-15 grains may be introduced.

### The Royal College of Physicians of London.

At this college the following lectures will be delivered during the present year:—The Gulstonian Lectures by Dr. Coupland on March 11, 16, 18—Subject, "Anæmia." The Croonian Lectures by Dr. Moxon on March 23, 25, 30—Subject, "Influence of the Circulation upon the Nervous System." The Lumleian Lectures by Dr. Southey on April 1, 6, 8—Subject, "Bright's Disease;" at 5 o'clock each day. Members of the profession will be admitted on presentation of their card.

THE rates of mortality per 1,000 last week in the principal large towns of the United Kingdom, were:—Brighton 16, Sheffield 16, Portsmouth 16, Wolverhampton 16, Birmingham 17, Bristol 17, London 18, Leicester 18, Newcastle-upon-Tyne 19, Bradford 19, Manchester 19, Salford 19, Plymouth 19, Glasgow 19, Leeds 20, Oldham 20, Hull 21, Sunderland 22, Liverpool 22, Edinburgh 22, Norwich 26, Nottingham 26, and Dublin 27.

*Land and Water* is authorised to state that the late Mr. Frank Buckland, M.R.C.S., whose obituary appeared in our issue of Dec. 22nd, has bequeathed his valuable Museum of Economic Fish Culture to the nation. The gift is rendered still more valuable by the fact that, according to his will on the decease of Mrs. Buckland, a sum of £5,000 will revert to the nation, to be applied for the purpose of founding a professorship of economic pisciculture in connection with the Buckland Museum and the Science and Art Department at South Kensington.

IN the principal foreign cities the rates of mortality, according to the most recent weekly official returns were—in Calcutta 41, Bombay 28, Madras 35; Paris 26; Brussels 21; Amsterdam 21, Rotterdam 23, The Hague 15, Copenhagen 23; Stockholm 34; Christiania 19; St. Petersburg

36; Berlin 26, Hamburg 23, Dresden 21, Breslau 28, Munich 24; Vienna 24, Buda-Pesth 27; Rome 33, Turin 21, Venice 27; Lisbon 36, Alexandria 42; New York 30, Brooklyn 24, Philadelphia 20, and Baltimore 20 per 1,000 of the population. Small-pox caused 18 deaths in Paris, 20 in Vienna, and 24 in Rome.

AFTER all there is *some* advantage in having a wife and children. From a comparative analysis of the statistical tables of suicides, for France and Sweden, M. Bertillon thinks he has established the following laws: (1) Widowers commit suicide more frequently than married men. (2) The existence and presence in the house of children diminishes the inclination to suicide in both men and women.

At a midnight service on New Year's Eve, the Rev. T. Thoresby, of Clerkenwell, referring to the care of bodies as well as of souls, made some pertinent remarks on the scandal at Guy's Hospital. He said we were afflicted with a strange anxiety and melancholy at the unexpected and unprecedented position in which one of them now stood. It was simply astonishing that a set of incapable governors, with priestcraft behind the scenes, aided by the agency and follies of a few superstitious women, should be allowed to ruin one of the finest hospitals in the country, and thus deprive multitudes of the poor of the inestimable benefits which the institution was capable of conferring upon them.

THE death-rate from the seven principal zymotic diseases per 1,000 last week in the large towns ranged from 0·5 and 0·9 in Brighton and Birmingham, to 4·5 and 5·4 in Sunderland and Nottingham. Scarlet fever showed the largest proportional fatality in Norwich, Sunderland, and Nottingham; and whooping cough in Sunderland, Nottingham, and Leeds. The highest death-rate from fever (principally enteric) occurred in Nottingham, Wolverhampton, and Portsmouth. Of the deaths from diphtheria, 16 occurred in London. Small-pox caused 18 more deaths in London, 1 in Dublin, but none in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

A PRO-VIVISECTIONIST.—At the forty-first annual meeting of the Scottish Society for the Prevention of Cruelty to Animals, held last week in Edinburgh, Mr. Josiah Livingstone presiding, a report was submitted showing that a large amount of good had been accomplished by the society's operations during the year, but that the expenditure had considerably exceeded the income. In the course of the proceedings a suggestion that the society should direct their attention to the question of vivisection was strongly opposed by Councillor Sloan, who declared that the saving of a single life was of more importance than the lives of all the cats and dogs put together. (Loud hissing, and cries of "Shame") He heard ladies hissing, but he said that a single human life was not to be compared to all the cats and dogs that are nursed and pampered in the New Town of Edinburgh. (Cries of "Shame," and the Rev. Mr. Fisher—"Life is God's gift to animals as well as to you.") He did not wish to sanction cruelty, but

where the discoveries of scientific men like Dr. Keith and others to be balked by mere sentiment? he was sorry to see people who, before they would give up pampered, wheezing brutes for scientific purposes, would rather give up their domestics. (Hissing, and great interruption). The suggestion was ultimately agreed to, as were several others of a like character.

THE REGISTRAR-GENERAL'S RETURNS.—The weekly return for the eight principal towns of Scotland for the week ending Saturday, December 25, gives the death-rate at 20·8 per 1,000 of estimated population. This rate is 4·3 under that for the corresponding week of last year, but 0·9 above that for the previous week of the present year. The lowest mortality was recorded in Glasgow—viz., 19·1 per 1,000—and the highest in Paisley—viz., 28·7 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3·7 per 1,000, being 0·5 above that for last week. Of these diseases scarlatina proved the most fatal. Acute diseases of the chest caused 124 deaths, being two more than the number recorded for the previous week. The mean temperature was 34·1, being 0·6 above that of the week immediately preceding and 5·6 below that for the corresponding week of 1879.

RELATIONS OF SCIENCE AND RELIGION.—Professor Calderwood has agreed to a request that he should re-deliver six of the lectures on the Relations of Science and Religion, given in New York during the month of October, in the Union Theological Seminary, on the Morse Foundation. The course of ten lectures was embraced in eight lectures for the convenience of the lecturer, and of these six will be given in Edinburgh next month. The subjects will include;—Matter and Energy, Organised Existence, Mr. Darwin's Theory of Evolution, Relation of Lower and Higher Organisms, Brain Structure, Man's Place in the Universe, and Religious Conception Assailed on Scientific Grounds.

GLASGOW DISTRICT BOARD OF LUNACY.—The Glasgow District Board of Lunacy met in the Council Hall on Friday last, when ex-Lord Provost Collins occupied the chair. The work at Kirkland's Asylum was reported to have advanced to such an extent that 40 or 50 patients would be received by the middle of next month. Other patients would be added weekly, as the workmen were cleared out of the premises, until these were fully occupied. It was stated by ex-Bailie Morrison that there would then be provided 1,170 beds, leaving a deficiency of from 430 to 450. The recommendation of the committee to the Board to offer to make an arrangement with Govan Parochial Board for the utilisation of their asylum for the pauper lunatics of the district was adopted. A letter was read from the general Board of Lunacy, in which they inquired "whether they are correct in believing that the disjunction of the Barony Parish from the Glasgow district, and its erection into a separate and independent district, would meet with no opposition from the district Board, but would be regarded as a satisfactory solution of the questions in dispute. It was urged by ex-Bailie Morrison that such a separation would defeat the intentions of the Legislature. The scheme that recommended itself to him was to keep Barony Parish as part of the district, use Woodilee Asylum for higher class patients, and erect plainer buildings for pauper lunatics who could be employed in out-door work. But he would be prepared to give the General Lunacy Board full powers in the matter, and he therefore moved—

That, in answer to the letter, the clerk be instructed to reply (1) that this Board having adopted the view that it would be advantageous to the district and beneficial to the insane poor if the whole of the lunacy arrangements were in the hands of one Board, and having used every means in their power to induce the various authorities to acquiesce in a

reasonable arrangement for the purpose, regret that they have not been, and are not likely to be, successful, unless adjusted compulsorily by the General Board of Lunacy; and (2) that it be intimated to the General Board that the Board will not oppose any measure which may be introduced into Parliament under the auspices of the General Board having for its object the restoration of the powers formerly possessed by the General Board to alter or vary any of the lunacy districts, either by combining counties or parts of counties, or dividing counties, or otherwise, as they may think fit.

Colonel Hozier recommended that discussion on the motion should be adjourned for a fortnight, and this was done.

### THE PUBLIC HEALTH OF DUBLIN FOR NOVEMBER, 1880.

The monthly report of Dr. Cameron, Superintendent Medical Officer of Health, which has just been issued, states that the deaths within the municipal area of Dublin were in the annual ratio of 36.55 per 1,000 persons living.

The deaths from the seven principal zymotic diseases were in the ratio of 5.52 per 1,000.

During the five weeks ended the 30th October, the deaths from zymotic diseases numbered 230; whilst in the four weeks ended the 27th November, the deaths caused by these maladies amounted to 126. This was the lowest zymotic death-rate during the year. The deaths during the last six months from zymotic diseases were as follows:

June ... ..	216
July (five weeks) ... ..	230
August ... ..	227
September ... ..	251
October (five weeks) ... ..	250
November ... ..	126

As compared with October, September, and August, there was a great falling off in the mortality from diarrhoea and measles. There was also, but to a less extent, a great decline in the fatality caused by whooping-cough.

On the other hand, there was an increased mortality from fevers (especially typhus), as will be seen by the following monthly death-rate from fevers:—

January (five weeks) ... ..	15
February ... ..	23
March ... ..	25
April ... ..	33
May (five weeks) ... ..	33
June ... ..	29
July (five weeks) ... ..	27
August ... ..	15
September ... ..	14
October (five weeks) ... ..	27
November ... ..	37

There was a falling off in admissions to hospital of patients affected with measles. Sixty-nine cases of typhus were admitted, as against 82 in October, 55 in September, 38 in August, and 45 in July. This disease is spreading in Dublin, and Dr. Cameron fears that it will increase very much.

The inspection of the dwellings of the artisan and labouring classes is being prosecuted vigorously. There is no doubt but that the bad condition of the tenement dwellings is a potent factor in causing the high death-rate of this city. There are, however, other factors just as potent, but perhaps even more difficult to remedy, such as intemperance, poverty, habits of personal uncleanness, improvidence and unskilful administration of earnings.

Dr. Cameron can confidently state that a decided improvement has been effected in the condition of a very large proportion of the tenement dwellings, though vast is the work still to be accomplished. The greatest improvement has been that effected in the methods for the disposal of refuse. The privies and ash-pits (always in direct communication) in the small and unpaved and unweeded yards of thousands of tenement dwellings are a great and serious nuisance; the stench from them

often pervades every room in the house. There has been no serious opposition made by house owners to the construction of water-closets, and during the last eighteen months, on an average, sixty per month have been put into the tenemental dwellings.

During the month twenty-five houses and six cellars were closed, being unfit for human occupation. In reference to the compulsory closing of tenemental dwellings, cases of hardship frequently arise as follows:—Poor men have houses upon lease, which they sublet; when these houses are closed they have to pay rent for them, though the houses have ceased to produce any rent. If the leaseholder puts the house into proper repair, he can of course re-let it; but very often he has no capital to expend in this way; and even if he did put the house into proper repair his lease might have only a short time to run. A lessee of seven houses in Wood Street, which have been closed nearly a year, is an example of this class of property-holders. He is unable to make the houses tenemental, which is practically to rebuild them; and his landlord insists upon his tenant paying the rent of houses which, in the interests of the public health, have been detenanted and shut up.

With reference to the proposed notification of infectious diseases, Dr. Cameron says: "In Edinburgh the medical attendant upon any person affected with an infectious disease is required by law to forthwith notify the fact to the sanitary authority, for which he is entitled to a fee of 2s. 6d. In nearly twenty other towns of Great Britain local Acts of Parliament require that the existence of infectious diseases should be notified to the sanitary authority—in some places by the physician, in others by the head of the household or other person in charge of the patient. A short time since a deputation, representing the medical corporations and societies of Dublin, waited upon the Lord Mayor to urge that the system of compulsory notification of infectious diseases should be adopted in Dublin, and that the Corporation should consider how the matter might be accomplished. Upon that occasion I was the only speaker who insisted that the duty of reporting such cases should devolve upon the physician, for otherwise the notification would not be given, in the majority of cases, by the persons in charge of the patient." At a subsequent conference between leading members of the medical profession and the Corporation, a change of opinion was evident amongst the former, several of whom, including the President of the Royal College of Surgeons, considered that the *onus probandi* of reporting infectious cases should rest upon the physician. I am glad that this view has been unanimously adopted by the Corporation. I trust that the Chief Secretary for Ireland, the Right Hon. Mr. Forster, to whom the Corporation have applied for assistance to promote a Bill for the compulsory notification of infectious diseases, may also be of opinion that the duty should be performed by the physician.

If the notification of cases of contagious diseases were a duty devolving on the "head of the family," I am quite sure that the middle and upper classes would not neglect it. As a matter of fact, when such cases occur in private dwellings, the owners are anxious to have the assistance of the sanitary authorities. They are glad to have their houses purified, and their bedding, &c., disinfected by the officials of the Public Health Committee. But, on the other hand, I am quite sure that the majority of the denizens of the tenemental dwellings would give either no, or a tardy, notice to the sanitary authorities; though it is in the cases of such dwellings that a prompt notice would alone be really useful. The local authority have no power to remove even a small-pox patient from a house in which there is proper accommodation for him; therefore, notification that a case of small-pox is in a fashionable house, is not of much use to the public; whilst notification, if promptly given, that a case of small-pox or typhus fever exists in a tenemental dwelling, every room of which is the abode of a whole family, is of the greatest possible hygienic importance. The prompt removal of persons suffering

from the serious forms of zymotic diseases to hospital, is one of the most efficacious measures for arresting the spread of these scourges of mankind. In even the most crowded tenemental dwellings, where four families have a common lobby, it is by no means uncommon to find one or more cases of small-pox or other zymotic disease. When the medical man called in to see such cases is a dispensary physician, he reports the matter to the sanitary authority; but this procedure is not followed, except occasionally, by private practitioners. Were the latter required by law to report such cases, I am quite sure that they would willingly do so, and thereby enable the sanitary authorities to enforce the removal of the patient to hospital, if his surroundings justified such action. The Society of Metropolitan Officers of Health (Dublin), at a meeting held on the 8th December, 1880, resolved that it was desirable that both the physician and the head of the family should notify. I think this resolution a good one. I find that in November of this year, out of a total number of 875 deaths, registered within the Dublin registration area, the cause of death was uncertified in 163 instances, and in 157 others there were "no medical attendants." It is evident, therefore, that the compulsory notification of contagious diseases (measles, for example, which is easily recognised) by the head of the family is necessary, as in many cases there is evidently no medical attendant.

#### SUPERANNUATION OF POOR-LAW MEDICAL OFFICERS.

(Copy of Circular by English Local Government Board, 14th December, 1880.)

SIR,—I am directed by the Local Government Board for England to state that their attention having been drawn to the diversity of practice existing amongst boards of guardians with respect to the superannuation allowances proposed to be awarded to Poor-law medical officers on their ceasing to hold office, the Board have considered it necessary to review the subject generally, in order to lay down, as far as practicable, the rules which should be followed in such cases. As these grants affect not only the present but future ratepayers also, the consent of the Board, as the guardians are aware, has been made essential to their validity, and consequently it is incumbent upon the Board to satisfy themselves that the sums proposed are reasonable and proper.

The Board have found that in many instances pensions have been submitted for their approval which were quite disproportionate to the length of service of the retiring officer; and that in some cases where the service has been comparatively short, and the officers have been appointed at very advanced ages, amounts have been proposed to be awarded equal to two-thirds of their salary and emoluments, being the largest amount which could be awarded under the Act after a period of forty years' service.

The refusal of the Board to ratify these grants has not only caused disappointment to the officers, but has sometimes led to lengthened correspondence with the guardians.

In order, therefore, to guard against these results, the Board think it right to inform the guardians of the definite rule which they have considered it necessary to lay down, and by which under ordinary circumstances they will in future be guided in dealing with this subject. In arriving at a decision it is unnecessary for the Board themselves to originate a scale, inasmuch as the Legislature in the statutes dealing with pensions in the Civil Service, and in the case of the officers of certain local authorities in the metropolis, has clearly indicated the principle which should be adopted in awarding allowances of this kind.

Following, then, the scale of allowances prescribed by the statute of the 29th Vict., cap. 31, the amount which may in the opinion of the Board be properly awarded to an officer who has served with efficiency for ten years or more, and for less than eleven years, will be an annual sum equal to ten-sixteenths of his salary, and emoluments at the time of his ceasing to hold office, with an addition of one-sixteenth in respect of each additional year of service, until a maximum of forty-sixteenths or two-thirds be reached, which is the highest amount authorised by the 27th and

28th Vict., cap. 42. At the same time there may be instances where for the due and efficient discharge of the duties of certain offices professional or other special qualifications are essential, and where the persons having such qualifications have been appointed when beyond the age of thirty years. In those cases a number of years not exceeding ten, may, for the purpose of computation, be added to the number of years during which the officers have actually served.

It is, of course, optional with the guardians whether, if they make a grant, it shall be on a lower basis than that above indicated, or shall be for a limited term only.

I am, Sir, your obedient servant,  
(Signed) JOHN LAMBART, Secretary.

### Literature.

#### A MOVABLE ATLAS, SHOWING THE STRUCTURE AND FUNCTIONS OF THE BRAIN. (a)

A SINGLE glance at Witkowski's Movable Atlas of the Brain, which would perhaps be more correctly designated a Movable Atlas of the Encephalon, for it includes a partial survey of membranes and vessels, and a complete delineation of the cerebellum and medulla oblongata, must satisfy every one competent to form a judgment on the subject, that it is well calculated to be of service to all who are called on to familiarise themselves with the anatomy of the cranial contents. To the student it cannot fail to be of essential use in keeping before him clearly and correctly all that his dissections have revealed to him of the structure and relations of the highest nerve centres, and to the practitioner it must often prove a very helpful boon, by reminding him of anatomical facts that are of an abstruse character, and easily forgotten, but that are daily assuming more and more importance in their relations to modern medicine. We can scarcely doubt, indeed, that this atlas will be conducive to the progress of cerebral pathology, by enabling observers who are not specialists to localise lesions of the brain with a degree of scientific precision that has not hitherto been practicable. Of the immense number of cases of cerebral injuries and degenerations that have been recorded heretofore, a large proportion have been valueless in the way of elucidating the all-important topic of localisation of function in the brain simply because they have not indicated with sufficient exactitude the seat of the lesions and degenerations which they described. But in future there will be no excuse for such indefiniteness, for the ingenious atlas which lies before us will enable any one accurately to particularise the site and extent of cerebral changes with a very trifling expenditure of labour. Hours of reading and cogitation will be saved by reference to its skilfully adjusted layers, which not only recal vividly the anatomy of the best books, but also convey information as to the most recent discoveries bearing on the functions of the crown of the nervous system. To those who are called on to prepare reports for medico-legal purposes in cases of fracture of the skull and wounds of the brain, this atlas will afford much valuable guidance.

The atlas consists of two maps, if we may call them so—dissected maps—but dissected not like a child's toy map, into co-adaptive fragments, but into a number of leaves or layers, which are so superimposed and hinged together, that they display, when folded back consecutively, the appearances and relations of the skull and brains in the manner in which they present themselves when they are systematically examined in the dead subject. To possess this atlas is really to have a typical skull and brain, beautifully dissected, and admirably demonstrating; their composition and arrangements lying always conveniently ready at hand, not as a *memento mori*, but as a *memento anatomica*. The first map presents a lateral view of the skull and face, exhibiting the bones of which they are made up, the sutures by which these bones are united, and indicating the temporal curves. On being opened, one side of the skull shows the dura mater lining of the skull, the distribution of the middle meningeal artery, the course of the lateral sinus, the arrangement of

(a) "A Movable Atlas, showing the Structure and Functions of the Brain." By Professor Witkowski, M.D. The Text Translated by T. Stretch Dowse, M.D. London: Baillière, Tindall, and Cox. 1880.

the turbinated bones, and of the interior of the mouth, and the extent of the frontal sinus, and the other, the position of the false cerebri, its relations to the longitudinal sinuses and corpus callosum, the distribution of the anterior cerebral artery, the position of the septum lucidum, the velum interpositum, the infundibulum, the pituitary body, the cerebral peduncles, the cerebellum, the pons variolii, and many other details, which it would take too long to enumerate. Between these two lateral views of the skull is a central leaf presenting views of one hemisphere of the brain on the outer and inner aspect, distinguishing the convolutions and motor areas, and all the bodies that are seen on a longitudinal section in the central line of the corpus callosum between the two hemispheres. A subsidiary leaflet, attached to one lateral leaf, supplies an excellent view of a section of the cerebellum through the arbor vitæ, and of the pons variolii, and medulla oblongata. The other map presents outwardly a view of the upper and under surface of the brain, with cerebellum and connected parts, and affords an intelligible representation of the convolutions on which are marked a few of the centres of movements which have been experimentally determined. These centres are, we think, too small in their dimensions, too sharply demarcated, and too few in number, for surely more than seven centres of simple and combined movements may be regarded as established. The convolutions, too, are perhaps too large and simple, and too symmetrical in their arrangements in the right and left hemispheres. It is, of course, desirable that their characteristic human arrangement should be unmistakably exhibited, but it might have been possible while doing this to show that they are invariably broken up, more or less, by secondary and bridging gyri, and that those of the occipital lobes are inferior in all their dimensions to those of the frontal and parietal lobes.

Apart, however, from such failings, which, perhaps, after all, lean to virtue's side, the views of the exterior of the brain are most creditably managed, and the way in which the numerous nerves and vessels at the base are displayed without confusion, and without violence to nature, is especially commendable. On folding back the leaves which form the upper surface of the hemispheres, we have a view on the right of the centrum ovale magnum, and on the left of a section at a somewhat lower level, affording an insight into the disposition of the corpus callosum, and the lobule of the insula. By the reflection of two more leaves, the lateral ventricles are exposed, and by three further unfoldings, the intricacies of their anatomy, and of that of their contents, nervous and vascular, are made wonderfully plain. The relations of the choroid plexuses, and velum interpositum, the shapes of the horns of the ventricles, the course of the fornix, the segments of the corpora striata, the different centres included in the optic thalami, with many other matters, are diagrammatically, and yet truthfully, demonstrated. It may afford some idea of the pains expended on this map, to say, that by a clever device, that fragile veil, the septum lucidum, is faithfully reproduced *in situ*. By a few leaflets at the base of the brain, the composition of the pons variolii, medulla oblongata, and cerebellum, the roots apparent and real of the cerebral nerves, and the contents of the fissure of Sylvius, are made apparent.

The text accompanying the movable atlas, which has been well translated by Dr. Stretch Dowse, is not so praiseworthy as the atlas itself. In thirty-one octavo pages, it professes to sum up the whole anatomy of the central nervous system, and its physiology to boot, with incidental treatises on the nature of nerve force, intellectual and moral acts, memory, sleep, and functional disorders. It is scarcely necessary to add that it is eminently superficial and shadowy. The value of the atlas, however, is not dependent on the text which is sent out with it, for it may be used to illustrate any standard work on anatomy.

## Novelties.

### AZYMOTE.

UNDER this name Messrs. Thwaites, of Dublin, who are well known as the oldest firm in the mineral water trade in Ireland, have introduced an effervescing beverage for which

they claim the duplicate merit of being a delightful beverage and a salicylic reagent. In the first of these capacities we can say that it possesses all the merits claimed for it, so far as we can judge, but we do not pretend to direct the palates of the public, or even of the more limited constituency for which we write. We have therefore obtained from Professor Tichborne, chemist to the Apothecaries' Hall of Ireland, the following report on "Azymote," upon which our readers can form their own judgment:—

"I have carefully examined the preparation known as azymote, described as a 'salicylated beverage,' and brought out by Messrs. A. R. Thwaites and Co. I believe it is patented by that firm, and this is probably the first instance of a medicine being patented as the essential ingredient in an alimentary substance.

"It gave on analysis as present in the fluid ounce—

Salicylate of sodium	...	...	35 gr. per oz.
Mineral matters, chiefly soda salt	...	...	14 gr. "
Citric acid	...	...	2.4 gr. "
Sugar with a little extractive and colouring matter	...	...	26.5 gr. "

It is non-alcoholic, but is strongly aerated. 'Azymote' is quite free from metallic impurities, and has a very pleasant flavour, in which oranges seem to predominate.

"It contains in each bottle nearly five grains of salicylate of sodium, which is perfectly pure and free from any carbolic acid. (Carbolic acid is a frequent impurity of commercial salicylic acid.) 'Azymote' will be a valuable preparation where salicylic acid is indicated, and its very agreeable taste renders it very pleasant to take as a beverage."

There can be no doubt that an enormous demand exists for non-alcoholic drinks, and that this beverage will supply that demand with a large section of the public. It will be most useful to the profession as a refreshing thirst-quencher in gouty rheumatic cases, for which it appears specially suitable. As to its merits as a therapeutic agent we know nothing as yet, but the idea of combining salicylic acid with a beverage is a good one, and it has been effectually realised in "Azymote."

## Medical News.

**Royal College of Physicians of London.**—The following candidates having passed the required examinations were admitted licentiates on December 30th, 1880:—

Allen, Thomas William James, University Hospital, W.C.  
 Bathe, Anthony John, 3 Whitlington Villas, London, N.  
 Bull, George Coulson Robins, 15 London Street, Farringdon, W.  
 Carpenter, Arthur Bristowe, Dappas House, Croydon.  
 Grayling, Arthur, Forest Hill, S.E.  
 Harvey, Sidney Frederic, 9 Catherine's Terrace, Lansdowne, Road, S.W.  
 Macdonald, Cameron Joseph Francis Stuart, 32 Osnaburgh St., N.W.  
 Maynard, Foster Fowler Martin, St. Andrew's Park, Hastings.  
 Mills, Thomas Wesley, M.D., McGill, 116 Murray Street, N.  
 Patten, Charles Arthur, Marpool House, Ealing, W.  
 Pearce, Walter, 62 Oxford Terrace, Edgware Road, W.  
 Phillips, William Alfred, Longton Grove, S.E.  
 Benschaw, Israel James Edward, Sale, Manchester.  
 Wilkinson, Frank Tichborne, 6 Dean Street, London, S.E.

**Royal College of Surgeons in Ireland.**—At the December meetings of the Court of Examiners the undermentioned were admitted licentiates of the College:—

Herbert Joseph Bermingham, Francis George Bonyngs, Shepland  
 M'Cormick Boyd, Francis Foster Brady, Louis John Patrick Carroll,  
 Arthur Gerard Chance, Francis Philip Golgan, Patrick Arthur Daly,  
 Valentine Plunkett Dillon, Charles James Douglas, Thomas James  
 Dowse, Frederick William Erham, Michael Edward Fitzgerald,  
 Thomas M'Craith Foley, William Gern, Michael Hayes, Patrick  
 Hoy, William Gardiner Jacob, William Wall Jacobs, Sidney Geo.  
 Jennings, Denis Patrick Kenna, John Keenan, Arthur William  
 M'Math, Henry Strickland M'Gill, Francis John Mulo'h, Daniel  
 Moon, Arthur Hill Murray, Reginald Lawson Morley, John Patrick  
 Nicholls, Daniel Butler Reardon, Wm. Smyth, John Joseph Stack,  
 Henry James Wyatt.

**Dublin Artisans Dwellings Company.**—The ceremony of laying the foundation stone of the buildings proposed to be erected by the company on the "Coombe Area" was performed by His Excellency the Lord Lieutenant, on Monday, December 19th, 1880, in the presence of a large and distinguished assemblage. The company, established in 1876, has since that year erected six blocks of buildings at a cost of about £35,000, and giving accommodation to between 13,000 and 14,000 people. It is a curious and instructive fact connected with the population on the company's property that the proportion of children under five years of age is double

that of the same class in the rest of Dublin. In other words, while there are ten children under five years of age to every hundred in the population of Dublin there are twenty children under five years of age to every hundred in the company's population. It is proposed to erect about two hundred cottages on the "Coombe Area" which has been cleared by the Corporation under the provisions of the Artisans and Labourers' Dwellings Improvement Act of 1875. These cottages will be of two classes, one a two-storied, the other a one-storied cottage, the object being to provide accommodation for the different classes in the neighbourhood. The two-storied cottage will contain one more room than the smaller one, and will also have larger rooms. The sanitary accommodation provided in each will be identical, and on the most approved system. The cost of the proposed buildings will be about £25,000. The directors of the company consists of Lord Ardilaun, chairman; Richard Martin, D.L., deputy chairman; R. O. Armstrong, J.P.; Robert Warren, D.L.; E. H. Kinahan, J.P.; W. Findlater, M.P.; and Hon. C. J. Treach. Mr. Edward Spencer, M.A., is secretary to the company, and who has also filled the post of assistant secretary to the Dublin Sanitary Association since its formation in 1872.

## NOTICES TO CORRESPONDENTS.

**THE INDEX.**—We are compelled to hold over the Index for the past volume to our next issue.

**ERRATA.**—Owing to the Christmas holidays, proofs of late articles in our last number did not reach the Editors in time for correction, in consequence of which several clerical errors crept in. In the section devoted to "England," under the head of "Literature," page 548, Mr. Reginald Harrison's book should read "Surgical Disorders of the Urinary Organs" instead of the "Surgery of the Urinary Organs." Under the head of "Scotland," second column, "Rentlessness" should be *Relentlessness*. Third column, ninth line, the quotation from Scott should read *unwept not unswept*. In fourth column, line 24, "voluntary" should read *voluntarily*. Seventh column, "professional," in line 21, should read *profession*. Bottom line, eighth column, in the Latin quotation, "Ambigues" should have been printed *Ambiguus*.

**DR. J. A. B.**—The surmise is quite correct.

**PRACTITIONER.**—Either Naphey's "Modern Medical Therapeutics," or Binger's "Hand-book of Therapeutics" will answer your requirements. We prefer Naphey for general practice, but Binger for students.

**A CONValescent.**—Our correspondent would no doubt derive much benefit by a month's residence at Ilkley Wells or Ben Rhydding Hydro-pathic establishments. If he prefers one nearer his present residence, there is a good institution of the same class at Leamington, called the "Arboretum," under the management of Dr. E. M. Owens.

**NAVAL MEDICAL CANDIDATES** are informed by advertisement in another column that the next examination of candidates for commissions in her Majesty's Navy will be held at the University of London on February 14th and following days.

**MR. R. H.** will find a reference to the subject of his letter in another column, present issue.

**LOST COPIES THROUGH THE POST.**—We are sorry to learn that, through the great pressure upon the postal authorities last week, several of our subscribers did not receive their *Medical Press* for Dec. 26th, some from wrong delivery, others through the bursting of wrappers. To all such who have not already applied for a duplicate, the publishers will be happy to forward one free of cost, on receipt of post-card.

**THE HARVEIAN SOCIETY OF LONDON.**—We are asked to correct the announcement made in our last that a paper would be read on Jan. 6th by Mr. Toynan. The order of papers has been somewhat altered, and tomorrow evening the annual meeting will be held instead at 8.30, to be followed by the Presidential Address.

**THE OBSTETRICAL SOCIETY OF LONDON.**—A similar error to that of the Harveian has been made in the notice cards sent out on behalf of this Society. Owing to an alteration in the bye-laws of the Obstetrical Society, the annual meeting will be held in future on the second, instead of the first, Wednesday in January. The meeting, therefore, announced for this week is postponed until next Wednesday.

**EPIDEMIOLOGICAL SOCIETY.**—Wednesday, Jan. 5th, at 7 p.m., Council Meeting.—8 p.m., Surgeon-Major Charles Oldham, "On the Nature and Origin of Climatic Fevers."—Dr. J. Wm. Mackenna, "On the Cause and Origin of Fever."

**ROYAL INSTITUTION OF GREAT BRITAIN.**—Thursday, Jan. 6th, at 3 p.m., Prof. Dewar, "On Atoms."

**HARVEIAN SOCIETY.**—Thursday, Jan. 6th, at 8½ p.m., Annual Meeting and Presidential Address.

**ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.**—Monday, Jan. 10th, at 8 p.m., Annual General Meeting.—Election of Officers for ensuing year.—President's Valedictory Address.—Mr. Geo. Wallis will show Mr. Lennox Brown's adaptation of the Lime Light.—Casual communications.

**NEW BOOKS AND NEW EDITIONS.**—The following have been received for review since the publication of our last list, Dec. 1st:—"The Clinical Society's Transactions," Vol. xii. Klein and Smith's "Atlas

of Histology," Part xiii. "Lectures on the Surgical Disorders of the Urinary Organs," by Reginald Harrison, F.R.C.S. "New Treatment of Disease by the Inorganic Turbide Cell-Salts," by Dr. Schüster. "Consumption as a Contagious Disease," translated from Prof. Cohnheim by Dr. Callimore. "Lectures on Domestic Hygiene and Nursing," by L. A. Weatherly, B.S. "Clinical Note-book for Hospital and Private Practice," by F. H. Fairbank, M.D. Lancercaux' "Atlas of Pathological Anatomy" translated by Dr. Greenfield. "Elements of Practical Medicine," by A. H. Carter, M.D. "Conscious Matter," by W. Stewart Duncan. "The Power of Movement in Plants," by Charles Darwin, F.R.S. "Hand-book of Midwifery for Midwives," by J. E. Burton, L.R.C.P. "Relapse of Typhoid Fever," by J. Pearson Irvine, M.D. "A German-English Medical Dictionary," by Faucourt Barnes, M.D. "Transactions" of the Pathological Society of London, Vol. xxxi., &c., &c.

**PAMPHLETS.**—The following have been received since the publication of our last Dec. 1st:—"On some of the Terms in common use among Medical Men," by H. Rabagliati, M.D. "The Influence and Use of the Will in the Treatment of Spinal Deformities," by Dr. Roth. "The Night Medical Attendance in London and other large Towns," by Dr. Roth. "Gastrostomy or Gastrostomy," by L. L. Stalon, M.D. "Twenty-fourth Annual Report of the Parish of Lambeth." "Whisky: The Process of Manufacture and Art of Distillation." "The Christiana Views of the Medical Profession." "An Account of Seventy-six Cases of Abdominal Section," by Lawson Tait, F.R.C.S. "The Antiseptic Theory tested in Ovariectomy," by Lawson Tait, F.R.C.S., &c., &c.

## VACANCIES.

**Ballinrobe Dispensary.**—Medical Officer. Salary, £120. Election, Jan. 17.

**Burton-on-Trent Union.**—Medical Officer and Public Vaccinator. Salary, £150, with the usual extra fees. Applications, endorsed "Medical Officer," to the care of the Clerk by Jan. 10.

**Donaghmore Dispensary.**—Medical Officer. Salary, £115. Election, Jan. 18.

**Dorset County Hospital.**—House Surgeon. Salary, £80, with board. Applications to the Chairman before Jan. 12.

**Lock Hospital, London.**—House Surgeon. Salary, £50, with board. Applications to the Secretary on or before Jan. 15.

**Granard Union.**—Medical Officer for the Granard Dispensary. Salary, £116. Election, Jan. 7.

**Manchester Royal Infirmary.**—Resident Medical Officer. Salary, £150, with board. Applications, with testimonials, to the Chairman by Jan. 22.

**Mountmellick Union, Coolrain Dispensary.**—Medical Officer. Salary, £105. Election, Jan. 10.

**Taunton Union.**—Medical Officer. Salary, £110, with the usual extra fees. Applications to the Clerk of the Union by Jan. 10.

## APPOINTMENTS.

**CREELY, J. H., F.R.C.S.E.,** Medical Officer to the Workhouse and the Aylesbury District of the Aylesbury Union.

**DOVONAN, R. E., M.D.,** Medical Officer to the Galbally Dispensary, Limerick.

**HINE, J. E., M.B.,** Junior Resident Medical Officer to the Radcliffe Infirmary, Oxford.

**KAYE, J., M.B., C.M.,** House Surgeon to the Huntingdon County Hospital.

**KIDD, P., M.B.,** Casualty Physician to St. Bartholomew's Hospital.

**MANSIAR, B. J., M.D., M.R.C.S.E.,** Physician to the General Hospital and Dispensary for Sick Children, Pocklington, Manchester.

**MORGAN, J., F.R.C.S.E., L.R.C.P.L.,** Medical Officer of Health for the Langport Rural Sanitary District, Somersetshire.

**MURRELL, W. M.D., M.R.C.P.,** Extra Physician to the North-West London Hospital.

**NETTLESHIP, E., F.R.C.S.E.,** Ophthalmic Surgeon to the Hospital for Sick Children, Great Ormond Street, London.

**SCHARBER, Dr. A.,** Resident Medical Officer to the German Hospital, Dalston.

**SHEILD, A. M., L.R.C.P., M.R.C.S.E.,** House Surgeon to Addenbrooke's Hospital, Cambridge.

**ARMY MEDICAL DEPARTMENT.**—The following were gazetted on Friday last:—Surgeon-Major C. G. Irwin, M.B., to be Brigade Surgeon, vice W. C. Roe, granted retired pay; Surgeon-Major R. O. Hayden, from half pay, to be Surgeon-Major.

**NAVY MEDICAL DEPARTMENT.**—The following was gazetted on Friday last:—Surgeon W. H. Colahan, M.D., has been promoted to the rank of Staff Surgeon in her Majesty's Fleet, with seniority of Dec. 28.

## Marriages.

**CARMICHAEL-BRIDGET-HAWES.**—On Dec. 29, at St. Luke's, Redell e Square, Daniel McGee Carmichael, M.B., M.C., of Portree, N.B., to Hannah Sarah, daughter of the late Mrs. Bridget-Hawes, of Priory Grove, South Kensington.

## Deaths.

**FRANKLIN.**—Dec. 26, suddenly, while presiding at a public examination of the Manchester Jews School, Isaac A. Franklin, M.R.C.S.E., of Fallowfield, near Manchester, aged 68.

**GOODMAN.**—Dec. 23, at his residence, Birkdale, Southport, Charles R. Goodman, M.D., late of Manchester, aged 43.

**HENSTED.**—Dec. 25, at Barnsbury, Edmund, eldest surviving son of the late Henry Hensted, F.R.C.S., of Speenhamland, Berks, aged 33.

**FRANTICE.**—Dec. 29, at his son's residence, 34 Campbell Road, Bow, Alfred Frantice, M.D., in his 76th year.

**RUSSELL.**—Dec. 21, suddenly, at Athlone Railway Station, Christopher, eldest son of the late Christopher Russell, M.D., of Enniserry, co. Wicklow, aged 43.

**TOULMIN.**—Dec. 23, suddenly, Abraham Toulmin, M.D., of Russell Road, Kensington, W., in his 84th year.

**WILSON.**—Dec. 28, suddenly, at Lancaster, Adeline Wilson, widow of Dr. W. J. Wilson, of Clay Cross, aged 40.

### ALCOHOL AS AN ANTISPASMODIC. (a)

By BENJAMIN WARD RICHARDSON, M.D., F.R.S.,  
President of the Medical Temperance Association.

(Continued from page 2.)

THE antispasmodic value of alcohol is realised again in other classes of disease or derangement, which have not, up to the present time, been sufficiently defined or recognized. I refer to conditions in which the balance between the impelling stroke of the heart and the recoil of the arteries is not in perfect order. In these instances we get the strange anomaly of a powerful impulsive heart, with a small feeble pulse, cold extremities, and pale surface of body. The persons in whom this condition exists are usually men of early middle age, of nervo-sanguine temperament, of active mental and physical habit, and of restless disposition. They are often men of letters, or artists, or are engaged in speculative business operations; and they are, as a rule, of rheumatic or gouty diathesis. Under undue pressure, hurry, or sudden fatigue they become suddenly unwell; they say they are prostrated and disposed to sleep, or rather feel as if they could not keep awake. They are lifeless by comparison with what they were, and they are conscious of great irregularity and palpitation of the heart. They digest badly; they complain much of cold; they complain much of giddiness, and they explain that they are nervous on the commencement of any public duty. The physical examination of these persons may show no organic disease of the heart, but an irritable and impulsive heart, with a very feeble pulse, and a low temperature. Let me take from my case-book one typical example.

R. S. is a clergyman by profession, aged thirty-six, of bilious temperament, and very much engaged in work.

He has suffered in early life from rheumatic fever, and still has occasional rheumatic pains. His appetite is fair; his sleep is fair; his memory, usually very good, is now enfeebled, and he feels physically weak. He is often dizzy, with a tendency to delirium, and when he commences to speak publicly he feels such loss of power in the loins, and muscles of the lower extremities he imagines he must fall. His face is pale; his extremities are always cold; his bowels constipated; the evacuations of clay-like colour, being sometimes firm and hard, at other times fluid and resembling yeast. The urine copious and pale, has a sp. gr. of 1018, but is free of albumen. The respiratory sounds are clear. The pulse is sixty-eight, and the three sphygmophonic indications are present, but it is so thin and small it is scarcely perceptible at the wrist. The heart sounds are clear, but with an occasional soft murmur at the base on the right side. The impulse of the heart is intense, and is described by the patient as a "persistent palpitation." In this case I commenced the treatment by carefully regulating the diet and regimen, withdrawing tea, and enjoying less work. As the patient was neither a smoker nor a drinker of alcohol in any form, I encouraged him to maintain abstinence in those respects.

The symptoms in these examples all point to the one deranged condition. There is an irritation, so to speak, extending through the whole of the arterial system, by which the resistance to the flow of blood through the body is impeded. This leads to a temporary impairment of nutrition, and to central nervous exhaustion. In plain terms, there is spasmodic peripheral resistance from an irritation which is felt by the heart itself.

In these cases, if attention be paid to the secretions as a preliminary; if the mind be relieved, as far as is possible, from worry; if daily exercise be enjoined, with early hours for going to bed; and if full quantum of sleep be secured, the symptoms often pass away without other aid; but this is not always the case, and when the phenomena continue alcohol with amyl nitrite, judiciously administered for a short time, is of signal service.

In the case I have recorded I prescribed first nitrohydrochloric acid with tincture of nux vomica and infu-

(a) Essay read at the First Meeting of the Session 1880-81 of the Medical Temperance Association.

sion of gentian, together with an alterative. This not succeeding, I prescribed iron and quinine (Easton's syrup). After some few weeks of failure—accepting the case to be one of the class described above—I ordered

Amyl nitrate, m. ij ;  
Alcohol, sp. gr. '830, ℥iij ;  
Liquid taraxacum, ℥ij ;

To make a dose to be taken three times a day, in a wine-glassful of water, after food.

The result of this treatment was immediate. It was like the result of an experiment. On the visit of the patient to me a week after the treatment had commenced the pulæ was full and soft, the heart's action was quick, the bowels were acting regularly, the mental activity had greatly improved, the body was of natural temperature, and the pulsation was much improved. At first the medicine produced some flushing and throbbing of the temples, but this passed away after two or three days, and in the course of a month the health was quite restored, on which the medicine was withdrawn. For fourteen months this patient has, I find continued well, remaining still a total abstainer from alcoholic beverages. He is now doing his full share of professional work.

Another class of cases resembling the above is often met with in which there is dryness as well as coldness of the skin attended with lepra or psoriasis. In these persons there is, as a rule, a syphilitic history, acquired or inherited. In them the action of the heart is intense, with a feeble pulse and nervous exhaustion. These are benefited by alcohol in properly-administered doses. I usually prescribe for an adult in such examples—

Liquid arsenite of potassa, m. v ;  
Pure glycerine, ℥i ;  
Alcohol, sp. gr. '830, ℥ss ;  
Distilled water, ℥i ;

To be taken in half-a-tumbler of water three times a day after food. In some instances I also add to this prescription two or three minims of the nitrite of amyl, and I have seen recovery, when arsenic alone has failed, commence immediately on the addition of the antispasmodic.

I have this week discharged a case of this kind, with recovery after five weeks administration of the mixture the formula for which is given above.

There is a third class of case belonging to this group, of which the phenomena are much the same, from conditions that are different as to origin. In the cases now referred to there is probably no resistance to the circulation of blood from undue contraction of arterial muscular fibre, but there is relative resistance, owing to the circumstance that the action of the heart is enfeebled, and cannot fairly overcome the natural tension.

The following case is in point. R. H. X. is a man of science, aged thirty-eight, following chemical pursuits. He is of nervo-bilious temperament and phthisical history. He is not a total abstainer, but moderately temperate. He smokes regularly. He suffered some ten years since from remittent fever. His appetite is fitful, his sleep restless and disturbed with dreams ; his memory is not so good as it was, and he is, physically, easily exhausted. He suffers from frequent "confusion in the head ;" is depressed in spirit ; is sometimes very irritable, and, as he expresses it, is always "vibrating." His temperature is now natural, but his extremities are usually cold. Pulse is 72, regular, and very feeble ; heart sounds are clear, but impulse very feeble ; the respiration natural ; the tongue creamy ; the bowels sluggish. The urine is clear and free of sugar and albumen, sp. gr. 1020. The facial expression is heavy and tremulous. There is no indication of organic disease of any kind, but extreme nervous depression, and heart-stroke is insufficient to overcome arterial resistance. I give this as a typical instance of a diseased condition in which, for a short period of administration, half a fluid ounce of '830 alcohol once or twice a day, with iron, if required, or nux vomica, or digitalis, is of the utmost service.

In the case named the alcohol was prescribed with Griffith's mixture, and with immediate benefit. The form ran as follows :—

Alcohol, ℥ss ;  
Tincture of nux vomica, m. v ;  
Compound of iron mixture (Griffith's) ℥j.

To be taken in half-a-tumbler of water twice a day after food. It was continued for three weeks, and then gradually removed, recovery being complete.

(To be continued.)

#### EXCISION OF THE WRIST FOR CARIES. (a)

By JOHN K. BARTON, F.R.C.S.I. ;

Lecturer on Surgery, Carmichael College, Dublin.

THAT Surgery took a step in advance when excision of joints began to take the place of amputation of limbs all gladly admit ; but when from this general agreement upon the merits of this branch of conservative surgery, we come to the question of the resection of particular joints, we find the greatest divergence of opinion among surgeons. With the exception of the elbow-joint, the resection of which may be said to have passed beyond the field of hostile criticism, there is not a joint in the body which may not be said to be at the present time a battle-field between rival schools—the advocates of excision in each case producing successful cases, while their opponents contend that these are but the exceptions to numerous failures, or that the successful cases would have made good recoveries without any operation. Truth will result from these contentions, and it is absolutely necessary that the *pros* and *cons* of each individual resection should be thoroughly discussed from all points of view—for the value of each operation can only be decided upon its own merits, and after considerable time has been allowed to elapse, so that the real result of the excision may be ascertained. In this way only can we hope to end the controversy, and arrive at a safe rule of practice in this most important branch of surgery.

In the case of the wrist-joint, all will admit the object which the surgeon proposes to himself to attain by excision is an important one—to save a hand from amputation, and restore to the patient a useful upper extremity. If, therefore, there are special difficulties attending this operation, not only, nor chiefly, in the performance of it, but also in obtaining, when properly performed, a useful hand with moveable fingers—these difficulties should stimulate us to greater perseverance, for, undoubtedly, if the excised wrist—even after a year—can be to some extent flexed and extended, the fingers closed and straightened, and the thumb approximated to them so that a pen can be held with firmness and guided in writing, a success worthy of much labour has been attained. The history of this operation is not a little remarkable. Performed for the first time by Moreau, the younger, at the close of the last century, there is no record of this bold and ingenious surgeon finding any imitator until 1839, when Deitz, a German surgeon, is said to have removed the ends of the radius and ulna and the carpal bones for caries. Ten years afterwards (chloroform having been introduced in the meantime), Heyfelder, excised the wrist, and it has since that time been followed by other surgeons, both British and foreign, with results, however, by no means encouraging.

Sir William Fergusson, writing in 1852, records a case of extensive caries of the wrist, in which he excised half an inch of the ends of the radius and ulna, the two rows of carpal bones, and upper ends of the metacarpal bones, by the lateral incisions. He says : "All the extensors and flexor tendons of the fingers were preserved. Also the radius and ulna arteries, with the median and ulnar nerves. There was very little blood lost, but the operation was protracted and difficult. The result was disappointing,

(a) Read before the Surgical Society of Ireland. Discussion will be found on page 29

for four months after the operation the hand and forearm were as useless as before the operation."

Mr. Doubled performed the operation after Heyfelder had published his cases in 1849, by two lateral incisions, in the same way, apparently, as Fergusson did his. But Velpeau recommended the lateral incisions to be joined together by a transverse incision across the back of the hand, the flap thus formed to be raised, by which the diseased bone to be removed could the more readily be reached. When we consider that the preservation of the tendons in their integrity is a cardinal point to be kept in view in our efforts to improve this operation, this flap made by section of all the extensor tendons, as recommended by Velpeau, seems a strangely retrograde step; and yet we find Mr. Butcher recommending an almost precisely similar method, under the title of "A New Operation," in 1864. Whether the operation Mr. Butcher performed has any claim to be considered new is a matter of less importance, being open to the same obvious objection that condemns Velpeau's, and as both have been superseded by Lister's method, which was published in 1865. In that year Mr. Lister recorded the particulars of 15 cases in which he had excised the ends of the radius and ulna, all (or nearly all) the carpal bones, and in some the carpal ends of the metacarpal bones as well. Of these 15 cases—writing three years after the first, and some months after the last case, had been operated on—he says: "Two have died of causes independent of the operation. Of the remaining 13, one is in an unsatisfactory condition, but not hopeless; two afford good hope of a satisfactory termination, which, in the remaining 10, may be said to have been already arrived at."

The method of incision employed by Mr. Lister seems at first to have been the same as that of Fergusson and Doubled, but, as his experience increased, he modified the lateral incisions somewhat, and recommended the outer or radial incision, to commence on a level with the styloid process, and at the middle of the dorsal aspect of the radius, from this to extend downwards and outwards towards the inner side of the metacarpophalangeal articulation of the thumb, but, on reaching the line of the radial border of the second metacarpal bone, to be carried directly downwards for half the length of this bone. The inner, or ulnar incision, he commences at least two inches above the end of the bone, anterior to it, and carries this down in a straight line to the middle of the five metacarpal bones. By making the radial incision in this manner the tendon of the extensor secundi internodii pollicis is avoided, as well as the radial artery, while the ulna incision is extensive enough to give room for the necessary dissection.

Lister specially directs attention to the necessity of removing all the parts of the extensive and complicated articulating machinery of the wrist and carpus, and also to the importance of preserving the tendons in as perfect a state as possible. He gives minute and careful directions for the attainment of this latter object, in the extent and direction of the incisions and the free movement of the tendons in their sheaths, both before and immediately after the operation.

Notwithstanding Lister's success, and the ample directions given by him for the performance of the operation and the after-treatment, but few surgeons seem to have followed his example. In 1868 Mr. Heeke reported a successful case by Lister's method, in which he removed the bones of the carpus, the end of the radius and ulna, and ends of the metacarpal bones. The patient, who had been a groom, was able to drive a brougham through London. Mr. West, of Birmingham, in the same year reported three cases, in all of which a successful result had been obtained, although in some sinuses had remained open, and bone had come away for many months.

Mr. Bryant, in the first edition of his "Surgery," published in 1872, after describing Lister's operation, says: "I have neither done or seen this operation. In exceptional cases it appears a good one." But in the last edi-

tion of his work he refers to Langenbeck's proposal of making one long dorsal incision, beginning over the back of the radius and extending downwards and outwards over the metacarpal bone of the index finger, and seems to prefer this, remarking that he has witnessed the facility with which the bones can be reached by this means.

Before concluding this brief history of the operation, I may remark that Lister's success seems to me to be attributable more to the sound principle of removing all diseased bones upon which he acted, and upon his careful and prolonged after-treatment, than upon his method of operating, which, however, in most cases will, I believe, be found to answer better than any other. The following are the records of my case:—Nourse Farquhar, 17 years of age, a writing clerk, was admitted to the Adelaide Hospital in March, 1880, for caries of the bones of the right wrist-joint. He had been an out-patient for two months, but as he was not improving, and suppuration was increasing, he was admitted into hospital. Upon examination, the affected wrist-joint was found to measure two inches more in circumference than the other. There were two openings on the posterior aspect of the joint, through which the probe came down on bone, which felt as soft as caries, and seemed to be the posterior surface of the radius. Anteriorly there were sinus openings, but these did not lead to denuded bone. As the disease was spreading, and the lad's health beginning to fail, it was evident that he must suffer amputation of his forearm, unless the hand could be saved by excision of the joint. The parents and the lad himself expressed an anxious wish to have the latter attempt made, so, upon the 27th of the month (March) I excised the wrist in the following manner:—Esmarch's bandage was applied, and the circulation in the wrist completely arrested. The part about to be operated on was then exposed to the carbolic spray, and the patient being fully under the influence of ether, I made two lateral incisions—the outer, from one inch and a half above, and a little behind, the styloid process of the radius, to the base of the metacarpal bone of the thumb; the inner from the same distance above the lower end of the ulna to the base of the fifth metacarpal bone. These incisions were carried down to the bones, and as soon as this was done I began to raise the soft parts, with the tendons, from the back of the radius and carpal bones on the outside, and from ulna and back of the carpal bones on the inside, keeping the knife close to the bones. This was accomplished very slowly and without much difficulty, but, in proceeding to clear the bones on the outside, the tendon of the extensor secundi internodii pollicis was divided. With this exception no tendon was severed. The first bone removed was the scaphoid; then half the trapezium was removed with a cutting forceps. This gave a free opening, and permitted me to dissect out the lunar and cuneiform bones, and then to examine the ends of the radius and ulna. The articular cartilages were destroyed, and the extremities of the radius and ulna were soft and carious; the blade of a Butcher's saw was then introduced in front of the bones, and section made of them an inch and a half above their articulating extremities. The bones forming the second row of the carpus were now carefully examined. Their cartilages were found to be perfectly healthy. The disease did not appear to have extended to them. Under these circumstances with a cutting forceps, I removed the cartilage-covered face of each bone, and, finding the osseous surface thus exposed healthy in appearance, I determined to lance them. The space between the bones, thus left, was two inches and a half. I did not attempt to bring their surface into apposition, but I merely drew them towards each other as far as the state of the soft parts would permit without much force being used. No artery required ligation. One or two small branches were twisted. A drainage tube was placed through the wound, which was then dressed antiseptically and laid on a splint supporting the fingers.

The after-treatment consisted in the daily free washing of the cavity, and in the constant passive movement of

the fingers. No inflammation of the arm followed, but there was a tolerably free suppuration, the wound being kept open on both sides. Gradually the parts contracted, and as they did the patient began to regain power over his fingers, and over his thumb also. The fingers were constantly moved to prevent their tendons becoming fixed in their sheaths. In three months he left the hospital, and attended constantly as an out patient. I examined him a few days ago, and took the following notes:—He is able to hold out his hand, but it drops a little when there is no support beneath it. He can flex and extend the hand to a limited extent. He can move all his fingers and his thumb, and approximate the thumb and fingers so as firmly to hold a lens between them, but he cannot flex his fingers freely into the palm so as to close his fist. The central part of the line of incision on each side is not quite healed, and there is a tendency to little ulcerations of the skin on the palm and dorsum from any pressure. These ulcers heal up readily. The measurement of the limb is as follows:—From olecranon process to tip of middle finger, 15½ inches; the distance on the second limb being 17 inches. Circumference round base of metacarpal bones, 6½ inches; the sound hand measuring 7½ inches. So that the hand is smaller by three quarters of an inch; and the forearm and hand lose but 2½ inches in length. With a light splint support he can write easily and lightly. Eight months having elapsed since the operation, the result in this case may be said to be satisfactory, and will probably be very much better in another year, for (as Sir W. Fergusson has remarked) from one to two years may be required in these cases to obtain the full benefits of the operation.

The case I have related differs from Lister's and any others (the report of which I have seen) in the fact that the articulating surfaces of the second row of the carpus alone were removed. The bones remain, and of course the metacarpus was not interfered with. I ventured to act in this way, because, in my case, the disease was chiefly in the extremities of the radius and ulna; and when I had removed the first row of carpal bones I was perfectly satisfied that I had removed all the parts engaged with disease, the remaining cartilages and bones presenting a perfectly healthy appearance and feel. The result shows that this may be safely done, when, as in my case, the disease was confined to the wrist-joint proper and the bones forming it, and had not as yet engaged the intercarpal joint and metacarpal joints.

## DISEASES OF THE HEART IN CHILDREN.

By W. H. DAY, M.D., M.R.C.P. Lond.;

Physician to the Samaritan Hospital for Women and Children.

(Continued from page 2.)

### ENDOCARDITIS.

THIS disease consists in inflammation of the endocardium or lining membrane of the heart, and is frequently associated with pericarditis as a consequence of acute rheumatism. It is most common in the latter affection, but may arise from exposure to cold, or be developed in the course of severe chorea, or scarlet fever, or measles, or small-pox. Bright's disease may induce a chronic form.

The general symptoms are a sense of discomfort and uneasiness over the cardiac region, anxiety of expression, flushed countenance, and a tendency to syncope. Pain is not always present unless there is pericarditis or pleurisy, and if auscultation were not practised carefully the disease might be overlooked. Still, in a few instances pain is severe, and increased on the slightest pressure or movement, so that the weight of the bed-clothes is intolerable. There is restlessness, hot skin, thirst and fever, followed by perspiration, which is often profuse as the disease advances; the pulse soon becomes

quick, feeble, or intermittent, and the breathing is hurried and abdominal. As the disease progresses the lips become livid, the eye is dim, and the face is dull and heavy, or pale and shrunk. Wandering at night, and even delirium and convulsions, are among the symptoms. Bronchial congestion, or pulmonary engorgement is apt to ensue from increasing debility, and the failure of the circulation through the lungs.

The physical signs are those indicating mischief at the aortic and mitral orifices as mentioned under valvular affections; there is usually a soft bruit at the apex with the systole, but the symptoms depend on the valves which are affected, and these are generally on the left side of the heart. The disease may terminate fatally from exhaustion and cerebral symptoms, or, if the acute stage be passed over, no traces of the disease may remain. In the most severe cases valvular changes ensue, leading to puckering of the valves and impairment of their functions, with ultimate obstruction of the circulation and general dropsy. A portion of the coagula may be detached from the curtain of the inflamed valve and carried into the general circulation, causing embolism.

In endocarditis as the accompaniment of rheumatic fever, there is an inflammation of the lining membrane of the heart. Effusion of lymph into the structure of the valves (*mitral valvulitis*) ensues, which finally becomes converted into a fibrous structure, the chordæ tendinæ are involved, so that they undergo contraction, and the valves becoming tied down or puckered up together, which either narrows the mitral orifice (*mitral stenosis*) or the opening is so wide, that when the ventricle contracts regurgitation is produced (*mitral regurgitation*). The mitral valve at each ventricular contraction has to sustain much greater pressure than the aortic valve which has only to bear the force of the returning blood against it.

*Treatment.*—This should in some measure depend upon the disease with which the cardiac affection is complicated, and seeing that it may arise in the course of acute rheumatism, or scarlet fever, it will be important to modify the treatment accordingly. The treatment is really the same as that of pericarditis, with which it is often associated, but there is this difference,—endocarditis speedily tends to exhaustion, and is not so amenable to active measures. The patient should remain in bed for a length of time after the acute stage has passed over, so that excitement may be diminished, and the effects of strain should be kept off the injured valves by lowering the blood pressure, as far as possible. This is recommended by Dr. Milner Fothergill, in a lecture, in the *Medical Times and Gazette*, Sept. 1878. "This fact then is ascertained and confirmed by experience, viz., that the damage done to the endocardium by rheumatic inflammation may abide for four or five years without producing any conscious detriment to the health or well-being of the patient, or (as far as we have the means of judging) any farther injury to the structure of the heart. And it is a most important and consolatory fact. But in other instances other results immediately follow. When after its departure acute rheumatism leaves the endocardial murmur behind it, which, though known only to the physician, is the sure sign of injury done to the endocardium, it leaves it attended from the beginning by other symptoms, which the patient is sufficiently conscious of, and these are directly referable to the heart. They consist of palpitation, pain, and dyspnoea, which are not constantly present, but only under bodily exertion and mental excitement. The child who has had the præcordial murmur ever since it suffered a certain rheumatic attack, is just the same child as it was before, except that it cannot join in any pastime requiring rapid movement; for then its heart palpitates, it loses its breath, and is obliged to sit down. Men too are just the same men as they were before, only perhaps they cannot run upstairs without panting and hurry, and they constantly find themselves obliged to restrain their bodily efforts within certain limits, and to beware of mental excitement, for fear of palpitation and dyspnoea."

These conditions too may remain for years without either augmentation or abatement. The murmur is never absent, but the palpitation and dyspnoea are never present except as the immediate effect of a certain amount of bodily exertion or mental excitement." (a)

*Myocarditis* or inflammation of the heart's substance is generally found in connection with endocarditis or pericarditis, but the muscular structure of the heart may be affected just as the muscles are in subacute or chronic rheumatism, without any inflammation whatever. Myocarditis occurs also in scarlet fever and in typhoid. After some fatal cases of endocarditis, the walls of the heart have been found to be thickened, and abscesses of variable size have been discovered in the muscular structure of the organ. Such changes occur in death from pyæmia, scarlet fever, and some other forms of blood-poisoning. If palpitation and violent pains in the cardiac region come on during rheumatism, and the pain extends through the shoulder, or passes down the arm, the disease may be suspected. The complaint being obscure in its manifestations, the treatment must be regulated in accordance with the most urgent symptoms, and the cause in operation if it can be discovered.

#### ULCERATIVE ENDOCARDITIS.

This disorder superficially resembles the form of endocarditis, frequent in rheumatic subjects, where minute coagula form around endocardial vegetations, and becoming detached, produce embolism in the cerebral and other arteries. But in ulcerative endocarditis the blood is preciously poisoned by some specific affection, as small-pox, pyæmia, diphtheria, &c., and coagula of infected blood form around the cardiac valves. Portions of these clots becoming detached, produce embolism of an infective character, over and above their purely mechanical effects. The disease attacks only persons of bad constitution.

For much of the description about to be given I am indebted to an interesting lecture by Dr. Cayley, on a case of "*Ulcerative or infecting endocarditis simulating typhoid fever in a boy aged nine years.*" (b)

The disease is to be distinguished anatomically by a large number of embolisms in the miliary form. The emboli in ordinary endocarditis are lodged in the middle cerebral artery, producing hæmorrhage and softening of the corpus striatum, and optic thalami, followed by hemiplegia. In ulcerative endocarditis they are deposited in the pia mater of the hemispheres, and do not necessarily produce any cerebral lesion. The intestine is frequently the seat of emboli in this form of endocarditis, and in both varieties the kidneys and spleen are the most common seats of embolism. The endocarditis of acute rheumatism may occasionally assume this variety, and it may even supervene on chronic valvular disease. (c)

The general symptoms sometimes resemble ordinary pyæmia; there are rigors, high fever of a remittent or

(a) Dr. P. M. Latham, "On Diseases of the Heart," New Syd. Society, 1876, vol. i., p. 279.

(b) A case in a boy, æt. 14, terminated fatally, through rupture of the heart, almost immediately after admission to the hospital. A year previously he had an attack of rheumatic fever, and since then had been losing flesh, and suffered from dyspnoea on exertion. A fortnight before admission he had severe pain in the chest, constant dyspnoea, and general malaise. When admitted there was a thrill, a double murmur, over the aortic valve, and a systolic murmur at the apex. "He suddenly became insensible, flushed in the face, and began to struggle, and then turned deadly pale, and died." A post-mortem examination showed that the "pericardium was full of coagulated blood, which had flowed from a very small orifice in a sac lying between the aorta and pulmonary vein, and which was formed by the protrusion on the part lying at the base of the mitral valve, in which destructive inflammatory ulceration had produced the lesion."—St. George's Hosp. Rep., 1874-76, p. 367.

(c) "The average weight of the spleen in ten cases of ulcerative endocarditis occurring in 1867-70 was 25 ozs.; they were always more or less soft and pulpy. Very rarely the spleen retains even to double the latter weight in endocarditis."—*Path. Anatomy*, by Wilkes and Moxon, 1875, p. 475.

intermittent type, and local suppuration. In other cases they resemble typhoid fever, as in the case recorded by Dr. Cayley.

In the typhoid form there are rigors and vomiting, often sweating, and irregular febrile exacerbations. There are also brown tongue, sordes on the teeth, and delirium passing to coma. The urine is often bloody and albuminous.

Auscultation discovers the signs of valvular obstruction, the murmurs varying according to the orifices affected, and the progress of the ulceration.

The disease tends to fatal termination, and is not controlled by treatment.

(To be continued.)

#### ON THE ADVANTAGE OF FURNISHING CATHETERS AND HOLLOW SOUNDS WITH CLOSELY-FITTING BOUGIES INSTEAD OF WIRE STYLETS.

By W. F. TEEVAN, B.A., F.R.C.S.,

Surgeon to the West London and St. Peter's Hospitals.

An elastic catheter is fitted with a wire stylet for one or all of the following purposes:—1. To keep the channel of the catheter pervious. 2. To stiffen it. 3. To give it a desired curve. In the case of a metal catheter, the wire stylet can serve the first object only. There are two distinct objections to the employment of the wire stylet:—(a) It usually fails to keep the tube clear; for if it get blocked with mucus, blood, or pus, no amount of manipulation will clear it, and the surgeon is obliged to withdraw his instrument, which, in cases of retention, is equally annoying to himself and patient. (b) When a wire stylet is used there is always a risk that its end may pass out at the eye of the catheter and prick the mucous membrane. This accident is very likely to occur when the surgeon is trying to clear the tube, and must be within every surgeon's experience. Now, if the catheter be fitted with a closely-fitting bougie, none of the above annoyances can take place. Unlike the wire stylet, which lies loosely in a cavity which it does not fill, the bougie accurately occupies the entire tube, so that no clot can enter. The bougie is, of course, not withdrawn till the catheter is in the bladder, when the rush of urine will be powerful enough to carry away with it any clot there may be in the bladder. When a catheter is used with a wire stylet, the cavity of the former is usually filled with mucus, blood, or pus before the instrument is fairly in the bladder. If the surgeon wants to stiffen the catheter, or give it a certain curve, a leaden or whalebone bougie, with a good rounded end, may be used. The French surgeons have for a long time fitted their bougies with fine shot or leaden stylets to stiffen them. For cases of retention on enlarged prostate, where there is often free hæmorrhage from the engorged veins, a metal catheter, armed with a closely-fitting bougie instead of a wire stylet, will be found a great improvement. All hollow sounds ought to be fitted with bougies, for the rattling of a wire stylet may give a sensation closely resembling the click produced by striking a small stone.

THE death-rate last week in the large towns from the seven principal zymotic diseases ranged from 0·7 and 1·0 in Plymouth and Newcastle-upon-Tyne, to 5·5 and 5·8 in Wolverhampton and Sunderland. Scarlet fever showed the largest proportional fatality in Sunderland, Bristol Oldham, Wolverhampton, and Norwich. The highest death-rates from fever (principally enteric) occurred in Wolverhampton, Norwich, Dublin, and Leicester. Small-pox caused 17 more deaths in London, but none in any of the other large towns.

## Clinical Records.

### ST. MARY'S HOSPITAL.

*Hypertrophic Synovitis of Knee-joint—Caries of Head of Tibia—Abscess of Tibia—Subsequent Suppuration within Knee-joint—Amputation—Rapid Recovery.*

Under the care of A. T. NORTON, F.R.C.S.

D. P., *æt.* 4 years, was admitted on the 9th April. His right knee-joint was swelled and painful; he was unable to walk in consequence of the pain in the joint. Spongy synovial membrane projected on each side of the patella, but it was evident that there was no pus within the joint, nor ulceration. On the 19th, there was, immediately below the joint on its outer side, a swelling, over which the skin was red. It proved to be an abscess, in connection with the head of the tibia. On the 22nd, an incision was made transversely over the head of the bone, and a sequestrum, the size of a bean, removed from the outer tuberosity. No communication had taken place with the joint, and a drainage tube of large size was therefore inserted, and the rest of the wound brought together with sutures. The operation was performed on strictly antiseptic principles. On the following day the temperature was 100 deg., and on the 24th, 102·8 deg.; thence it fell, on the 26th, to 98 deg., and so continued, with a rise every night of two degrees, until the 5th of May, when it rose to 103·2 deg. About this time some children in the ward were attacked with scarlatina, and it was noticed that the skin of the abdomen of this child was somewhat efflorescent in appearance for about two days, but he had no sore throat. He was, however, moved into an isolation ward. For four days the temperature was 103 deg. every evening, whilst the knee symptoms seemed abating, so that it is probable that the boy suffered from a light attack of scarlatina, especially as some small quantity of albumen was passed in the urine at a later date.

From the 10th of May to the 20th the temperature was that of hectic or suppurative fever, varying between 99 deg. and 101 deg., being always two degrees higher in the evening than in the morning, though still the signs of knee-joint disease did not increase in severity. On the 20th of May the temperature rose at night to 102 deg.; and on the 21st, it being found that pus had collected in the joint, an incision was made into the joint under the antiseptic spray, and about four ounces of pus evacuated. On examination of the joint by the finger, all the bony surfaces were found denuded of cartilage. Large drainage tubes were inserted, and the joint dressed antiseptically every other day. A great quantity of discharge was found in each dressing, but the pulse remained at about 95, and the temperature did not rise above 99·6 deg. until the 3rd of June. Desquamation of the chest and abdomen had been taking place during the past week. The child now suffered from diarrhoea and catarrh of the external ear, during which the temperature ranged between 99·5 deg. and 101·3 deg., reaching the latter every evening. From this date to the 24th of June there was little or no change in the symptoms. Suppurative fever continued, the temperature rising a degree and a-half to two degrees every evening, the highest temperature being 102·2 deg. Food was refused, or taken only in small quantities. The nights were sleepless, and the sweats of hectic were exhausting. The discharge from the knee continued in quantity, and was somewhat offensive; there was no sign of repair going on within the joint. The patient was therefore placed under chloroform, and a thorough examination made. Nearly all the cancellous tissue of the head of the tibia had been destroyed, leaving a large abscess cavity surrounded by carious bone. The abscess opened both externally and into the joint. It was decided that the disease extended too far into the shaft of the tibia to allow of excision, apart altogether from the consideration of the constitutional condition of the patient,

and that amputation should be at once performed. Amputation of the lower third of the femur was performed on the 28th of June, under antiseptic principles, and on the 29th the temperature was 99 deg. After this date the temperature remained within a tenth of a degree either above or below normal; the flaps healed mainly by the first intention; and with the subsidence of the fever, signs of health returned.

Within a week of the operation, antiseptic dressings were discontinued, there being no wound; and in the third week after the operation, the patient was discharged cured.

## Transactions of Societies.

### SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, December 10th, 1880, in the Albert Hall, Royal College of Surgeons, Dr. M'CLINTOCK, President of the College, in the chair.

Mr. JOLLIFFE TUFNELL, F.R.C.S.I., Hon. Sec. read the minutes of the previous meeting, which were confirmed.

#### PEFUNGULATED MYXO-FIBROMA.

Mr. THORNLEY STOKER exhibited a myxo-fibromatous tumour, about as large as a goose-egg, removed by him on the previous Wednesday in the Richmond Hospital, from a female patient, *æt.* 36, multiparous, and exceedingly healthy in appearance. The tumour grew on the right side of the orifice of the vagina on the muco-cutaneous junction, immediately behind the termination of the nymphæ of that side. It had existed about fifteen years, and caused little or no inconvenience during that period, the growth being gradual and slow. It was a good example of that character of morbid tissue called myxo-fibroma. About its periphery where most firm; it was fibromatous, but towards its centre it was myxo-fibromatous. It was encapsuled, and fortunately the ligature had included the pedicle immediately beyond the capsule, thereby securing the woman against the risk of its recurrence. The reason she presented herself at the hospital was that she—some-what unjustly—conceived the tumour to be the cause of a swelling in her right leg, to which she had been subject since a certain confinement, after which it had appeared.

#### KNEE-JOINT EXCISION.

Mr. W. WHEELER showed sections of the left femur and tibia which he removed on the 2nd ult. from a girl, *æt.* 19, in the City of Dublin Hospital, when performing resection of the knee-joint. She suffered from synovitis two years previously, and had been treated in a Dublin hospital with benefit; and afterwards probably, from the appearance of the affected parts, articular osteitis set in, and later the synovial membrane altered in structure. The joint was two inches larger than the healthy one circumferentially over the patella, and much pain was evinced on pressure at the inner side of the tibia, and when it was made against the femur, but up this latter bone there was no thickening whatever. On closer examination of the synovial capsule, it presented all the appearances described as pulpy thickening. The crucial ligaments were congested, but not ulcerated. The cartilages, as demonstrated by the specimen, were raised from the tibia, but not diseased, and underneath each cartilage might be seen the erosive and carious condition of the tibia, and the widening of its articular end. The femur was carious at its outer condyle, but the rest of the articular surface was perfectly healthy.

#### KNEE-JOINT EXCISION.

Mr. HENRY GRAY CROLY exhibited a specimen also connected with excision of the knee-joint. A man, *æt.* about 28, was admitted within the last three weeks, under his care, in the City of Dublin Hospital, suffering from the usual symptoms of cartilage erosion, stiffness of the limb, and excessive pain on any movement. Though his family were not very healthy, he (Mr. Croly) thought, as the disease was very limited, he would give him a chance by excising the joint. It was interesting to find the disease limited entirely to the cartilage, which was completely eroded with a perfectly healthy

bone underneath. The specimen was interesting, as it was not usual to get a case where the disease was confined entirely to the cartilage.

#### MAMMARY CARCINOMA.

Mr. W. M. WHEELER exhibited a breast which he removed from a female patient on the previous Tuesday. It showed a tumour scirrhus in character, but the specimen, being in the incipient stage and the early date of diagnosing and removing it, had some points of special interest not seen in what might be termed fully developed scirrhus of the mamma. The nipple was retracted, but there was no dimpling of the skin—another mark of its early stage—contraction sufficient to produce that condition not having taken place. On cutting through the tumour the surfaces of the section became concave, being characteristic of that form of growth. It had no distinct capsule, which was seldom found in scirrhus—indeed, stated upon high authority not to exist. But last session he had had the opportunity of showing an encapsuled scirrhus breast, since preserved in the museum. The tumour presented a pale greyish colour; it was intersected by ducts and yellow lines, which belonged to the texture of the breast. The outlines of the lobes were not yet obliterated, but only blunted. Mr. Abraham, the curator of the college museum, had made a microscopical examination, and stated the specimen to indicate “commencing cancer.” The microscope, No. 2 on the table, showed a section which presented all the characters of the disease. He (Mr. Wheeler) added that the patient was about 42 years of age, and healthy in appearance. She had no family history of special disease of any kind, and was attracted to the tumour by occasional pain.

#### EXCISED WRIST-JOINT BONES.

Mr. HENRY GRAY CROLY exhibited all the bones of the carpus, and the end of the radius and ulna, which he had removed from a patient in the City of Dublin Hospital, by Lister's operation of excision of the wrist.

#### MAMMARY CARCINOMA.

He next exhibited a specimen of a scirrhus breast which he had removed on the previous Monday from a patient, *æt.* about 45. The tumour had been growing about six months, and was very hard. The most interesting point in connection with the case was, that although he felt two glands under the edge of the pectoral muscle, when he prolonged the incision he felt a long chain of small lymphatic glands running up under the scapula, and to the apex of the axilla, and he was able to shell them out with his fingers.

Mr. J. K. BARTON read a paper on

#### EXCISION OF THE WRIST.

which will be found on page 24.

Mr. HENRY GRAY CROLY said he had had occasion to excise the wrist-joint by Lister's method three times, and had a case on which he intended to perform the same operation on the following Tuesday. Those cases he had not yet published, awaiting the efflux of two years to see how they would progress; for although the operation might look very nice at the time, he could not speak of its usefulness without due trial. However, so far he had reason to believe the patients were going on well, having useful hands. Should the opposite result ensue, he would nevertheless publish the facts, detailing exactly how the cases had terminated. Last March he had had an opportunity of seeing Professor Lister operate himself. What struck him as remarkable about it, and as contrary to what he had at first recommended, was his being favourably disposed to partial excision of the wrist-joint. He cut down on the wrist-joint, and finding the disease in the end of the radius and ulna, he removed the first row of carpal bones. Then finding the rest of the carpal bones healthy, instead of cutting out all the carpal bones, he removed the cartilages of the second row, doing away with the necessity of removing a greater extent. Having asked was he afraid of leaving disease, Prof. Lister replied that he had had more than one case where partial excision proved satisfactory. In excision of the wrist-joint, as in excision of the knee-joint, success depended on the selection of the case. Meeting a case where the cartilage on the end of the radius and ulna was diseased, with limited disease on the carpal lines, he would select that for a good result. But if the disease was extensive, involving a large section of the radius and ulna, the result could not be satisfactory. Thus resection had been

brought into disrepute by ill-selected cases, men excising joints because it was the fashion, instead of carefully selecting their cases in which to do so. He had asked Mr. Barton why he removed so large a piece from the end of the radius, and his reason was that the end of the bone was so soft he was naturally afraid to leave it. With regard to the steps of the operation, but for Esmarch's bandage he did not know how it could be performed at all. In using Esmarch's bandage for that operation and operations affecting the hand, it was useful to apply the bandage only above the elbow, the elastic bandage being calculated to leave a paralytic condition. He detached the pisiform bone. The great object to be gained was a fixed wrist and movable fingers. It was important to make the section of the ulna with an oblique incision so as to prevent any displacement of the hands.

Dr. E. H. BENNETT, judging from the information before the Society with the specimen exhibited, congratulated Dr. Barton on the result of the case, and also on his determining on the operation, because evidently the condition of affairs was such as to demand the operation. Still, were Dr. Barton to do the operation over again, with the light the specimen revealed, he would doubtless limit his incisions in the bone to a very great degree. He was quite certain that the specimen afforded no evidence of disease to the extent to which the removal had been made. In that remark he did not intend any unfriendly criticism, as there was great difficulty on deciding the degree or limit of disease during an operation. From the dry specimen the disease appeared to be limited almost to the styloid region of the radius. The carpal bones at the radial joints were very healthy, so that had the incision been limited to a much smaller area of bone a far better result would have been obtained. It reminded him of a specimen in the College—the first case of excision of the knee performed by the late Sir Philip Crampton—remarkable for the extraordinary length of bone which, through inexperience of the operation, had been removed. Instead of such shavings as Mr. Wheeler exhibited there were three or four inches of the shaft removed. So that it was a wonder any successful result could ensue. He suspected Dr. Barton would bear out his observations in reply.

Mr. WHEELER said he had, towards the end of 1874, excised the wrist-joint in a girl of very strumous habit. She had several sinuses over the region of the joint, and on pressure she complained of the usual pain. He performed excision according to the method described, removing the metacarpal bones, the end of the radius and the ulna. He did not “Esmarch” that case, nor would he, if performing excision of the knee-joint, again use Esmarch's bandage. It was not requisite to use Esmarch's bandage, causing great delay in the operation, and consequently unnecessary distress, and perhaps shock to the patient. His experience was, that there was enormous bleeding after the removal of the bandage, and small vessels would have to be tied which need not be, had it not been used. The plan was to elevate the limb and then put Esmarch's bandage on the main artery, having bandaged it evenly without the elastic bandage, or merely have it raised up. Thus there was no secondary hæmorrhage or weeping where so many small vessels had to be tied. Esmarch's bandage caused unnecessary delay, and he would not use it again in excisions of the wrist, or knee, or ankle. The case to which he alluded had turned out favourable, although the sinuses remained until 1877, more than two years and several months after the operation, but that was not, in his experience, an unusual thing in cases of strumous joints, and even in cases of amputations performed on strumous patients. Change of air, and other causes, building up the patient's health would cure the sinuses which the surgeon could not speedily heal. In his case the little finger remained slightly stiff, but the other fingers were very useful. It was not Lister's splint that he used, but it was like it, with a large pad of lint underneath. With regard to the specimen exhibited by Dr. Barton, the os magnum appeared to be very extensively diseased, the front portion of it being taken away. He concurred with Dr. Bennett as to not removing so much of the radius. The sinuses he felt perfectly certain would close after a time. As to the question raised by Dr. Barton, the main point was undoubtedly the selection of the cases for operation. An apparatus invented by Mr. Fagan, of Belfast, shown at the meeting of the British Medical Association in Cork was very ingenious and useful, produc-

ing extension and counter-extension, and keeping the wrist-joint perfectly at rest. A great number of favourable results had been produced by that line of treatment, as the statistics proved. The splint was most useful in cases of incipient disease of the wrist-joint. In the City of Dublin Hospital he had a patient from the north of Ireland suffering from disease of the wrist-joint. He put on a splint, not Dr. Fagan's, but he adopted the same plan of extension and counter-extension, and the man got perfectly free from the pain and the spasms in the wrist, and had almost perfectly recovered without operative interference.

Mr. THORNLEY STOKER did not intend to trouble the Society, but an issue had been raised so important and so much at variance with all the opinions he had learned to hold that he could not remain silent. If there was one thing more than another he learned to have belief in, it was in the use of Esmarch's bandage in excisions of joints. Every day he had seen it employed he was the more strongly impressed with the belief that it was one of the greatest advantages gained by modern surgery in the performance of its operations. He had, therefore, heard with some surprise—he might almost say dismay—a gentleman of considerable experience in that class of operations speak against the use of the bandage; and he could not but think some erroneous facts must have been stated with regard to it. Esmarch's apparatus consisted of two things—an elastic bandage and an elastic tube tourniquet. Mr. Wheeler had condemned the whole apparatus from beginning to end.

Mr. WHEELER interposed and said he had not gone so far. In removing portions of bone from the foot the bandage was very useful; but in excisions of the knee or the wrist-joint he would not use it.

Mr. STOKER said he had never performed excision of the wrist, but he had several excisions of the knee, deriving the greatest possible assistance from the use of Esmarch's bandage. He had not a single objection to offer to it. When first brought into use, the tube apparatus was often too tightly applied, and in some of the London hospitals paralysis ensued; but he doubted that such a result had ever occurred in Dublin. He had seen it employed in scores—aye, hundreds of cases without the slightest ill-effects. In the early use of the bandage he had seen partial anæsthesia result, but not such as Mr. Wheeler had condemned it for.

Mr. WHEELER said the reason he would not use it was, that it induced secondary hæmorrhage and caused delay. He never spoke of paralysis in connection with it.

The PRESIDENT observed that the main question was not the use of Esmarch's bandage.

Mr. STOKES—If that is out of the scope of the discussion I have nothing more to say.

Mr. O'GRADY said the advantage of Esmarch's bandage was, that it enabled the surgeon to see the condition of the bone, which was of great importance; but at the same time he agreed with Mr. Wheeler as to the troublesome consequences that followed in the way of hæmorrhage. So much had he experienced the difficulty spoken of by Mr. Bennett as to determining where to limit the removal of the bone, that of late he had used a chisel in preference to a saw.

Dr. BARTON replied, Mr. Croly had mentioned the operation he had seen Mr. Lister perform—the one which he did in leaving the second row of the carpus; and the lesson taught by his case was strengthened by Lister's. He did not wonder at Dr. Bennett's remark, inasmuch as the dry specimen did not show the amount of disease that certainly appeared at the time of the operation. The end of the radius seemed so soft and carious as to necessitate, in the opinion of himself and his colleagues who assisted him, a freer excision than they had at all wished. It might be that further experience would enable one to gauge more accurately the exact quantity of bone to be removed; but as Dr. Bennett remarked, it was not easy, when performing the operation, to do so. Being impressed with the soundness of the principle to remove all the bone that he was satisfied was diseased, he thought an error upon that side was after all the safest. In his case the bones of the first row of the carpus were comparatively free from disease. The encrusting cartilage was diseased, but the bones to a slight degree only were affected; the second row of the carpus not at all so. That was why he stopped short here. By saving a second row of the carpus it still remained an open question whether he might or might not have saved more of the radius and ulna; but those bones at the time of the operation seemed so far engaged that to ensure a thorough removal of the

diseased part it was necessary to make the section where he did. Still, his case showed that even with that amount of bone removed a useful hand might be obtained. With regard to the discussion on the Esmarch bandage in connection with that particular form of operation, he could not help thinking that it was exceedingly valuable in enabling the surgeon to see what he was doing and to do it better than he otherwise could. He thought the advantages it afforded in that particular class of operations was very great, and he would decidedly use it in those cases, as well as in others where the bones were primarily the parts to be operated on. But in many cases it was by no means easy to gauge the amount of pressure with the constricting-tube. An assistant would exert an amount of needless pressure to make the arteries secure. Dr. M'Ewen, of Glasgow, uses a piece of elastic itself instead of the tube; and he had done so, too, finding it sufficient to restrain the circulation and far less liable to dangerous pressure. The os magnum could not be the seat of disease, inasmuch as, except the head, it remained in the lad's hand at present, and was exceedingly useful.

The Society then adjourned.

### ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

WEDNESDAY, DECEMBER 15TH, 1880.

W. A. N. CATTLEIN, F.R.C.S., President, in the Chair.

MR. EDMUND OWEN read a paper on

#### MAXILLARY ABSCESS AND NECROSIS IN CHILDHOOD,

and remarked that the question which he was about to suggest for discussion (for the enlightenment not only of himself, but also of many other practitioners) was this:—Is it right to refuse to extract a carious and aching tooth on account of the acuteness of the periosteal and maxillary inflammation, which its presence has excited? Honestly, he did not know what answer he should get, or he should not have gone through the superfluous performance of coming there that evening for the information. He could assure them that it was a matter on which the knowledge of general surgeons—speaking for others as well as himself—seemed by no means definite; and as it involved pathological and surgical principles of great importance, it would be well if existing haziness could be cleared up by the Fellows of this Society expressing their decided opinion on this question. He was prepared to find that their answer would not be absolute and free of all reserve, though, for his part, he strongly held that the dental surgeon should never refuse to extract a tooth which was the probable cause of acute peri-dental inflammation, for the simple reason that the local disturbance was excessive. He now desired the Fellows to accompany him, in imagination, to the general out-patient room, whilst we examine two sufferers whose cases, by analogy, have considerable bearing upon the question which this paper proposes. The first case is that of a little boy, who is in a most miserable condition, with a large bright red or dusky swelling at the end of his thumb. His mother tells us that he can neither eat nor sleep on account of the pain and throbbing in his hand and arm. When the dressings are removed, we see that he is suffering from acute inflammation of the bed of the nail, and we learn that a week or ten days ago the little fellow had his thumb violently squeezed in a doorway. The nail is evidently doomed. It is discoloured and loose, and, attached by one side only, its jagged base and edge are imbedded in a bleeding groove of vascular and irritable granulations. The condition of the parts leaves no doubt as to what should be the line of treatment adopted. The nail must be removed, so as to set the tissues at rest, and so as to allow of the escape of some unwholesome discharge, which is at present partially concealed beneath. As soon as this is done, water dressings are applied, and cod-liver oil and iron prescribed; and the boy from that time begins to recover health and strength. No treatment which did not include the removal of the nail would have been of avail. The other case is also that of a child. His right leg, from the knee to the ankle, is so full of heat and pain that he is unable to stand upright. Indeed, his condition is one that urgently demands his admission into the wards, and, if possible, instant relief. As we are following him upstairs, we learn from his mother that, though hardly a strong boy, he was really never ill till within the last week, and that she attributes all his trouble to

the fact that, just before the attack, he was exposed for some hours to the wet and cold of a snowy day. On examination, we find that he has acute periostitis and inflammation of the bone itself, with, probably, some sub-periosteal suppuration. Mr. Owen was sure the Fellows of the Society would agree with him in this—that the proper local treatment consisted in making bold and free incisions down upon, and even into, the inflamed bone. And if a bystander asks if we are going to cut into this hotbed of congested vessels and energetic leucocytes, he may be answered that such treatment is indeed appropriate, inasmuch as it at once relieves the vascular tension, and diminishes the chance of the inflammatory vigour, determining the death of the adjoining osseous tissue. There is just one other patient he would yet like to examine; but as he was going to obtain their opinion and advice upon this case shortly, he would, with their permission, examine him by himself. At the first view he had of him, he concluded that he had something wrong with his teeth, for his mother had bound up his chin and the lower part of his face with a thick comforter, and with it a decomposing mass of moist linseed meal. He found the cheek red and swollen, hard, and tender; and on getting a peep into the mouth between the jaws, which he could only slightly separate, he found that all the teeth on the bad side were encrusted with a yellow fungus—a sure sign that for some time the little patient had been unable to use that side of the mouth for mastication. In a similar way a stone roller lying idle beneath the damp trees becomes covered with a sickly growth of moss. By the aid of a better light, one discovered that one of the molars was a little decayed, and that the gum surrounded it with a bright red line. Moreover, when he pressed upon the cheek in the swollen part, a small quantity of ill-smelling pus wells up between the tooth and gum. He also noticed that near the angle of the jaw was a small opening, from which matter is discharging. On asking if the patient has suffered much of late from toothache, the mother says "Yes," but the child, apprehensive, says "No." He learns that he has neither eaten nor slept of late, and that the cheek, before it began to discharge, was much more swollen than it is now. On asking the mother how it was that she did not suspect that a bad tooth was the cause of the pain and swelling, she replied that she did suspect the tooth, but that, when she took the boy to the dentist, that gentleman said that he would not take it out until the inflammation had gone down. Those, she said, were his very words. He also advised her to keep on poulticing the cheek. And now let us follow out briefly the course that the inflammation, which is started from an inflamed tooth pulp, will take. The local disturbance having caused paralysis of the vaso-motor nerves, the Haversian arteries become crowded and blocked with the red corpuscles. The colourless corpuscles effect their escape, together with some of the liquor sanguinis, through the thin-walled vessels, and the protoplasmic contents of the lacune and canaliculi take on energetic proliferation. But the sum of the changes to which the nutrition of the maxillary tissue is subjected is not yet complete. At last the intravascular pressure becomes unrestrainable, and, the walls of the vessels giving way, the bone becomes flooded with sanguineous effusion. Further, healthy nutrition being in these circumstances impossible, a certain portion of the jaw perishes, and, becoming surrounded by a more or less complete shell of new osseous tissue, frees itself by a tedious process of linear ulceration, and remains as a sequestrum. Into the question of subsequent operation we need enter no further to-day than to say that the less the wounding of the skin, and the less the disturbance of the young teeth, as the dead piece of bone is being removed, the better. Whether the sequestrum is to be removed through the mouth, or by way of the sinus which opens near the angle of the jaw, must be determined by the nature of each individual case. The writer then evidently assumes (as he speaks again of the wound being over the angle of the jaw) that it is the inferior maxilla which is the seat of the necrosis, and such is his intention. He is under the impression that necrosis of the superior maxilla is rare compared with that of the inferior, and that for the simple reason that the bony substance of the former is less dense than that of the latter, and is therefore better calculated to suffer from acute inflammation without serious result; and that, moreover, when its elements are engaged with inflammatory products, a certain amount of the strangling pressure is enabled to expend itself harmlessly upon the walls and cavity of the antrum of Highmore. This is, however, a matter well worth discussion, from an anatomical point of view, the author confining himself to a statement of the fact that, in his

experience, necrosis of the superior maxilla in childhood is rare, whilst that of the inferior is not uncommon. Mr. Owen then drew attention once more to the boy into whose acutely inflamed tibia were made those firm incisions but a short while ago. The local bleeding has now ceased, but it has afforded a complete relief to the vascular and nervous tension, and, freed from pain, the little patient has fallen into a calm sleep. Nor is this the only result. Our energetic treatment has afforded a vent to the effused products, and has saved the compact bony tissue from a fatal flooding. Let us imagine, if we can, that there had already been a sort of vent-peg firmly driven into that inflamed osseous area—how gladly we would have availed ourselves of it to ease the bursting pain in the leg! By prising or pulling, somehow or other, we would have got it out, and so the parts would have settled down in quiet. And if we had happened to know that that imaginary physiological peg had been the starting-point of all the local mischief and constitutional trouble, we would have effected its removal with vindictive delight. And surely these very conditions have obtained throughout the whole course of that other child's maxillary distress—each in its proper order. There was the diseased vent-peg (though no imaginary structure), the unsound tooth, wedged into, and causing acute inflammation of, the maxillary tissue. Probably its prompt extraction would have spared the sufferer much subsequent trouble. Mr. Owen readily admitted that, even early in the course of events, the jaws may have been rigidly approximated by sympathetic irritation or inflammatory thickenings, so that it became impracticable to apply the forceps to the crown or broken body of the tooth. He could, therefore, well understand that a gentleman, whose only other dental instrument was that quaint but desperately powerful tool, the "key," might content himself with advising poulticing, or even the application of poppy-head fomentations to the face; but in such cases the most appropriate instrument was the "elevator," by means of which the tooth can readily be attacked from the outside. He would consequently venture to affirm that, whenever a child is brought for dental assistance, the more firmly fixed the jaws, and the greater the inflammation in that certain area, the more imperative is it that the irritating tooth and the vascular tension of the adjacent bone be simultaneously removed. Even if the operation should not be perfectly successful as regards the extraction of the entire tooth, the treatment will have done good. Indeed, the local bleeding alone may have sufficed to obtain rest for the parts; whilst, if the whole of the tooth be lifted out, the tissues will settle down in quiet as happily as did that red and swollen finger-tip when the removal of the piece of damaged nail was effected. The particular matter, then, in conclusion, upon which he sought information from surgeons practising dental surgery was this:—"Was it right to refuse to extract a carious and aching tooth because of the acuteness of the periosteal and maxillary inflammation which its presence had excited?"

The PRESIDENT was glad that Mr. Owen had brought under discussion in his practical paper an unskilful kind of practice which greatly increased human suffering, and was often very injurious to the patient in after life. It was the erring practice of some to wait until the inflammation subsided; but if the tooth be retained, the swelling, as a rule, rapidly extends to adjoining parts, and sometimes causes necrosis, occasionally infiltration into muscles, restricting the movements of the jaw, and often ending in abscess, which, bursting externally, permanently disfigures the face.

Mr. W. A. N. CATLIN then brought before the Society a case which happened in his practice, some years ago, of a young man, *æt.* 19, looking as if suffering from blood-poisoning. The water and drainage of his house were good, and he had never been to sea. The breath was fetid, but not so bad as that from necrosed bone; and the gums presented a somewhat warty appearance, the larger lobules being of a peculiar blue colour. The upper and lower extremities were studded with patches like ecchymosis, and he had suffered slightly from diarrhoea. No symptoms of purpura hæmorrhagica were seen in the mucous membrane of the mouth or any part of the body, nor did the growths resemble epulis, or ordinary granulations in a congested state. There was no evidence of syphilis. The treatment consisted in a plentiful supply of fresh air, generous mixed diet, with four ounces of port wine daily. Full doses of chlorate of potash and decoction of bark were administered, which were subsequently changed for mineral acids and sulphate of iron and quinine. Under this treatment the patient slowly recovered—and, in all proba-

bility, was a case of scurvy brought on by other than the usual causes.

## Special.

### ARMY MEDICAL ITEMS.

WE learn that a sufficient number of candidates have given in their names to compete at the examination to be held next February to justify the hope that all vacancies at present existing in that service will not only be filled, but that a tolerably close contest for appointments may be anticipated. This is indeed good news, and we hail it with much pleasure.

\* \*

BUT is it the case that while candidates for the Navy and Indian Medical Departments obtain their commissions in their order of merit according to the joint results of their examinations at Burlington House and Netley, those for the Army obtain theirs according to the former only? This difference is said to damp the zeal of those who are undergoing probation—an unfortunate result, no doubt, and one to be deprecated; nevertheless, it does not appear on what grounds a different rule applies to them than to candidates for the other two branches of the public service.

\* \*

Is it the case that since the development of unification comparatively few medical officers of the army become candidates for membership of the military clubs? If such be the case the circumstance is to be regretted, at the same time that the existence of an impression that it is so indicates what we fear really amounts to an isolation of a class of the members of one of the most important branches of the army, of which they ought to be in all respects an integral part.

\* \*

THERE are rumours in the air to the effect that the Secretary of State for War, conscious of the evils already produced by the system of compulsory retirement of regimental officers has in contemplation a plan by which this hardship to themselves may be in some measure lightened. There is need for some such measure, also for medical officers who have been, and those who may expect soon to be, similarly shelved. With regard to both classes the tax-payer, when he sees the army estimates for next finance year, may be expected to inquire as to the why and the wherefore of the considerable increase to be shown under the head of non-effective pay.

\* \*

A "SOCIETY" journal indicates the coming Director-General, alas! not in flattering terms. Whatever evils to the interests of the public service and of individuals have resulted from *unification* are rightly or wrongly attributed to him, whom our talented contemporary delighteth not to honour.

\* \*

A LARGE quantity of medical stores and "comforts" has been dispatched by the *Dublin Castle* steamer to the *Transvaal*. The following medical officers and establishments have already proceeded or are about to proceed to the same destination, namely—By the *Queen*: Surgeons-Major Smith, Thompson, Giraud, and Leask, Brigade Surgeon Roch, and Surgeon Cross; of the Army Hospital Corps, four non-commissioned officers and men proceed by the same vessel. By the *Hankov*: Surgeon-Major Lealie, Surgeons Brown, Drury, Lealie, and Powell; 2 officers, 38 non-commissioned officers

and men of the Army Hospital Corps. By the *Ararat*: Surgeon-Major Scanlan, also 14 non-commissioned officers and men of the Army Hospital Corps.

REGISTERED FOR TRANSMISSION ABROAD.

THE

WEDNESDAY, JANUARY 12, 1881.

### THE NOTIFICATION OF DISEASE.

THE provisions of the Contagious Diseases (Animals) Acts have been sufficiently long in force to have proved the vast benefits that follow from them, both locally and generally. Whereas in former times diseases contracted by one or more of a herd of cattle might or might not be communicated to the other members of the same flock, according to the energy and enlightenment of their owner or his dependents, it is now impossible that an infected animal should continue as a source of danger to its fellows for a moment after its condition has once declared itself. It is then forthwith isolated, and subject to the direction of an official inspector, it is systematically treated for the removal of the disorder from which it is suffering. In this way wholesale spread of disease after the fashion common before the Contagious Diseases Act became law, is impossible, and any alarming epidemic is arrested ere it has time to assume any considerable proportions. In the light of all the good that has been wrought by applying such measures of precaution where animals are concerned, it is surely no improper wish to desire the extension of the rules they embody to human beings; and with this object in view a small association is at present working to secure governmental assistance in the matter. Necessary as the sought for legislation is, and anxious as we are to witness the application of law to the notification of infectious disease, we yet cannot help a fear lest

the success of any movement to secure it may be hampered by unwisdom in the management of details. In order that the fullest measure of good may accrue from the working of any set of rules which may be formulated, it is necessary that they shall be wisely and liberally framed to allot the labour of the work they necessitate when it will be faithfully performed. It has been suggested to require the medical attendant to notify every case of infectious disorder with which he is brought in contact; and at first sight it may seem that this is a reasonable and just demand. But it ought to be remembered how onerous and continuous are the duties of a medical man, especially when his practice lies in country districts, or sparsely inhabited country townships, and how the actual toil of each day's proceedings leaves nothing either of inclination or of power for the performance of acts not immediately necessitated by the duties of the day. It is easy to see how in this way the registration of an infectious case may be deferred over night "to the following morning," and then possibly in the hurry of a sudden call, forgotten until the return at night, when again, through bodily exhaustion, it is found utterly impossible to do anything in connection with it until a night's sleep has refreshed the wearied body. And it could not be said of this explanation for neglect that it did not supply a legitimate reason for it, and an excuse from the infliction of any fine attached to the non-observance of the notification process. It is an wholly unjustifiable tax on the time of the medical attendant to demand of him that he shall acquaint the public registrar of the occurrence of every case of infectious disease he is called upon to treat. It may, however, be very properly required of him that he shall inform the responsible occupant of the house in which such disease is found of the nature of the disease, and also direct him how to proceed in order to conform with the law, which provides for the notification of infection. Such action would involve no sacrifice of time, and would amply meet all the calls of the situation. It might still be optional with the medical practitioner to make a personal report of the case, thereby relieving the first responsible person; but in any such case it should be clearly understood that the responsibility is delegated, and the penalties of non-compliance also. For this reason it may be preferable to confine the responsibility to a single person in every case, and that person, in the interests of every party concerned, ought to be the occupant of the house or room in which the disease broke out, or in those cases where the occupant is the one attacked, the medical officer should be empowered to depute the office of notifying its outbreak to some other person in the said home.

That a system of registration of the kind proposed would be a public benefit there can be no possibility of doubt. It has long been recognised by the profession as one of the most pressing needs in the way of aiding progress in preventive medicine, and even those who failed at first to see in it anything save an interference with individual rights, have been gradually influenced to perceive the great benefits that would accrue from universal adoption of its principles. Notification would, as a matter of course, lead to isolation when this proceeding had not been already observed, and thus would be secured the

best possible means both of preventing the spread of disease, and adopting curative measures where it existed. The measure can be productive of good alone, and it is much to be desired that the efforts to secure its adoption may be successful.

### THE SMOKE AND FOG NUISANCE.

THERE is no denying the fact that the smoke nuisance is greatly on the increase in large towns, and the injurious effects on health of the too oft visits of dense black fogs are subjects of grave and pressing importance to the inhabitants. We cannot, however, shut our eyes to the fact that there are unusual difficulties in the way of enforcing remedial measures, and bringing about an abatement of the evils so loudly and justly complained of. This was seen and admitted by all who took part in the Mansion House Meeting on Friday last, under the Presidency of the Lord Mayor of London, for the purpose of taking into consideration the best means of dealing with, and lessening the smoke and fog which, in winter time, so seriously vitiates the atmosphere. The first resolution, moved by the President of the Royal Society, embodied views, such as have become familiar in various ways. It is equally satisfactory to receive an assurance that a special Committee, consisting of Professors Abel, Frankland, and Russell, had been appointed to conduct a scientific inquiry into the conditions of the London atmosphere. This is a preliminary step of importance, as there are points to be cleared up, and it is quite necessary to start with a full view of the nature of fog and its mode of formation, before one can hope to suggest a useful remedy. It is, however, tolerably certain that for the production of fog, we require a combination of minute particles of dust and soot, with the floating atoms of watery vapour. Professor Tyndall long ago showed experimentally that in all cases when the vapours of the liquids employed are sufficiently attenuated, no matter what the liquid may be, the visible action commences with the formation of a blue cloud, which only requires a certain surrounding of darkness to become most disagreeably apparent. During some periods of the year the atoms of a blue cloud have been known to hold in suspension cholera germs. Such clouds are always more or less loaded with fungoid and other deleterious matters. In all forms of combustion, the elements required to produce a foggy atmosphere are freely given off with the sooty particles, mixed with a large quantity of sulphur; and it is estimated that about 200 tons are produced for our lungs to consume in the course of each winter's day. A goodly portion of this sulphur necessarily comes from the large combustion of gas, at the same time every ton of coal burnt produces 160 pounds of aqueous vapour. Here then we have ready to hand, favoured by meteorological changes nearly all the conditions necessary to form the densest fog cloud. However, the Government is apparently alive to the necessity of lessening the danger to health. The Chief Commissioner of Works has avowed his desire to assist in the movement inaugurated by the joint committees of the National Health and Kyrle Societies. We have every reason to believe that some-

thing will be done, and before very long. Mr Shaw-Lefevre in a speech, which elicited the applause of his hearers, moved a resolution embodying the views set forth by the joint committee. He believes that the injurious effects of fog are mainly owing to the immense quantities of smoke sent forth from the chimnies of manufactories, to wit, the Lambeth potteries, the river steam boats, railway engines, and such-like, as well as dwelling houses; and that the smoke of the metropolis might without difficulty be greatly lessened by the better enforcement of the existing law, by the introduction of proper smoke-preventing apparatus, smokeless coal, and the introduction of improved household stoves and grates. Manufacturers, we should think, will scarcely require to be compelled to consume their smoke if they are at the trouble to think for a moment of the saving to be effected, which amounts to from seven to ten per cent. of the fuel consumed, by the use of a simple smoke-consuming apparatus. When, however, we come to deal with the domestic hearth, the open fireplace is too deeply rooted an institution to be lightly dealt with and abandoned. No doubt the distribution of anthracite coal for north country coal would be a decided improvement, but public opinion requires a good deal of educating on the matter, and it is first necessary to show that a great economy can in this way be effected in domestic expenditure. It would, however, be wise of the gas companies to turn their attention more directly to the supply of gas for heating and cooking purposes, and then at no distant day we may hope that the atmosphere of London will be ultimately restored to a more natural and wholesome condition.

#### MEDICAL REFORM IN THE NEW PARLIAMENT.

NOTICE of a Bill to amend the Medical Acts has been given in the House of Commons by Mr. Hardcastle, M.P., and we have reason to hope that this measure will be the representative Bill of the profession, and that no other proposal of law will be laid on the table of the House on behalf of the professional organisations which have, in previous sessions, put forth separate legislative schemes.

We hope, next week, to be in a position to give our readers full information as to what has been done, and is doing, in regard to medical reform. For the present we are only permitted to say that the representatives of all those parties who have made medical reform their special business, have been active and earnest in the matter, and have arrived at a most gratifying condition of unanimity as to the nature of the proposals to be put before Parliament in their name.

For many years the prospect of medical reform has never looked so hopeful as at present, and, although the state of affairs in Parliament is undoubtedly not favourable for class legislation, yet there is every chance that, if the profession stands shoulder to shoulder when called upon to do so, every detail of medical reform which it has sought for will be achieved.

DR. JOHN FINIGAN, of Glasnevin, co. Dublin, has been presented with an address and a valuable service of solid silver plate.

## Notes on Current Topics.

### The Physiciancy to the Queen in Ireland.

THIS office of honour vacated by the death of Dr. Hudson has, at length, been conferred on Dr. Benjamin George McDowel, one of the most popular and best esteemed physicians in Ireland. The gentleman, thus distinguished by Her Majesty, took the surgical license of the Royal College of Surgeons in Ireland in 1841, being the son of Dr. Ephriam McDowel, an equally valued physician of his day. In 1845 he became a Fellow of the same College, in 1846 he became a licentiate of the London College, and in 1853 took the M.D. of the University of Dublin. For three consecutive periods of seven years he was elected Professor of Anatomy and Chirurgery in the School of Physic attached to the University; his lectures, in this capacity, being chiefly physiological, and, during the same period, he served as one of the clinical teaching staff of the House of Industry Hospitals, and of Sir Patrick Dun's. Since his connection with the School of Physic ceased, he has been associated with the College of Surgeons, first, as a Councillor, and, at present, as a member of its Court of Examiners, but his practice has been principally as a consultant in medico-chirurgical cases. The personal qualities and professional status of Dr. McDowel give a fitness to the appointment which Her Majesty has been advised to make, and we congratulate him upon his new honours.

### Another Nursing "Difficulty."

THE warning we threw out a short time ago proves to have been only too much required, and one of the largest and most important of the metropolitan hospitals seems about to enter on a path of destruction that will ultimately lead it to ruin as complete as that which has overtaken Guy's. There will be little excuse to be made for the staff and governing body of the threatened institution if they fail to profit by the experience gained in the contest at Guy's Hospital. The original cause is apparently the same in the East-end as it was in the borough—viz, a new matron. We hear this official has inaugurated her reign by a wholesale discharge of the probationers, and that she contemplates extensive "innovations." Devoutly do we hope that the religious mockery which has distinguished the proceedings at Guy's may find no imitation at the East-end, and that we may be spared the pain of witnessing afresh the wanton disregard of all humane considerations for the sake of ostentatious piety. The staff of the great London charity we refer to is generally regarded as being made up of men who are slow to act against conviction, and who cling with unyielding strength to the principles that approve themselves by their own great excellence. We shall be surprised, indeed, if these gentlemen consent to subject themselves to the petticoat dictation about to be introduced over them. The contest may be a sharp one, but it will be short and decisive we feel convinced.

### "The Blues."

AT this period of the year, more particularly than at any other time, the obstacles that have to be contended

against in "keeping well" are many and serious. Fog, cold, damp, and wind, all combine to work their worst on the constitution and the mind of the healthy and the invalid alike. Hence, it is that the utmost determination will alone avail, at times, to free one from the presence and consequences of what are by common consent termed "the blues." The blues is not by any means a disease, but it is a symptom, and an important symptom of general unfitness that is deserving of careful attention. Neither can it be regarded as being due to a single disturbing element, it is rather a compound sign of complicated disagreements calling for equally associated remedies. The digestive organs have a good deal to say in the causation of "the blues," and they ought to receive more than ordinary attention at those times when the atmospheric conditions unite to influence susceptible temperaments. The nervous system so readily re-acts to digestive disturbances that too much attention can hardly be directed to them, especially when, as lately has probably occurred, an undue tax on their powers has been imposed. General recognition of the fact that "the blues" is a sign of some disturbance in the system, and that their dissipation will assuredly follow on the correction of the altered condition, will do much to remove one of the most distressing of the troubles incident to civilisation and over-feeding.

#### Pathological Society of London.

At the annual meeting of the Pathological Society of London, the retiring President, Mr. Jonathan Hutchinson, briefly addressed the members of the Association, and congratulated them on the good work being accomplished through their exertions. The system of exhibiting specimens by card has been found to work admirably, and Mr. Hutchinson deserves, as he has received, the hearty thanks of the general working profession for introducing so efficient a means of instruction. The office-bearers for the coming year were elected as follows:—President: Dr. Wilks. Vice-Presidents: Drs. George Buchanan, Thomas Buzzard, Andrew Clark, James E. Pollock; Messrs. Christopher Heath, Jonathan Hutchinson, S. James A. Salter, Septimus William Sibley. Treasurer: Dr. George Johnson. Honorary Secretaries: Dr. Joseph Frank Payne, Mr. Henry Morris. Council: Dr. Thomas Barlow, E. B. Baxter, J. Cavafy, S. Coupland, Sir Joseph Fayrer, Wm. Ord, Douglas Powell, G. H. Savage, F. Taylor, T. Whipham, W. B. Kesteven; Messrs. W. Marrant Baker, J. N. C. Davies-Colley, Warrington Haward, H. Howse, Joseph Lister, R. W. Parker, W. J. Smith, Warren Tay, W. J. Walsham. It is satisfactory to hear that the financial position of the Society is sound, and that the close of the year finds it richer by £100. The strength it exhibits by its possession of 635 members, too, speaks well for the value of the work that it may be looked to to accomplish in the future. It is in every way a flourishing and invaluable institution.

#### St. Thomas's Hospital Paying Wards.

The block of buildings at St. Thomas's Hospital which was devoted to the use of paying patients some little while ago, it is announced, will be opened immediately for the receipt of cases. A resident medical officer has been appointed, upon whom the general care of the inmates will

devolve; but special professional attendance may be secured at the personal choice of the patients, who will, in this case, bear all extra expenses thereby incurred. We explained at some length on a former occasion on what terms the regular staff of the hospital will be with regard to the paying patients. Their relation to them will be precisely that of any legally qualified practitioner, and nothing more, their services being available, when required, as that of an ordinary consultant. The scheme has every chance of success at St. Thomas's, and it will be disappointing if it do not work in a manner to reach beneficially to the general public. Infectious diseases are rightly excluded, and also chronic or incurable cases.

#### What Influence has Race on Insanity?

DR. E. C. SPITKA (*Jour. Nerv. and Mental Diseases*, October, 1880), presents the results of a study of this question in the New York city asylum for the insane. He finds that, on the whole, the different forms of insanity occur in the same proportions, nearly, in the Anglo-Saxon, Teutonic, Celtic, and Hebrew races; paralytic insanity is most common among Anglo-Saxons, and least common among negroes; melancholia is most common among the German peoples; the tendency to terminal dementia is greater in the Anglo-Saxon than the German or Celt; and the forms dependent upon hereditary taint are most common among Hebrews. With this it is in accord, that since that termination in dementia and the influence of heredity are the factors which chiefly cause an accumulation of the insane population, that the Hebrew and the Anglo-Saxon should have the highest proportions insane of their respective populations.

#### Symptoms of Adhesion to the Pericardium.

M. DUROZIEG furnishes (*L'Union Med.*, Sept. 7, 1880), a very interesting paper upon this subject, giving numerous records of cases in detail, as well as the reports of the autopsies when the latter were made. He concludes as follows: Inspection of the pericardial region is very important in the diagnosis of adhesion of the pericardium, and the results should be carefully distinguished from those of palpation. The eye and the finger give opposite indications. The latter gives the sensation of a propulsion where the eye sees evidently a depression. This movement of retreat of the apex and of the pericardial surface during systole is a very good sign of adhesion of the pericardium, but is not absolutely pathognomonic. In very rare cases it exists without adhesion. Hope mentioned it first. As other signs of adhesion we have a continual movement of the pericardial surface, trembling of the apex during the second sound, sound similar to that produced by compressing a sponge. Sudden death is not rare in this affection. The patients very rarely pass or ever reach fifty years of age.

The rates of mortality per 1,000 last week in the principal large towns of the United Kingdom were as follows: Newcastle-upon-Tyne 16, Portsmouth 16, Sheffield 19, Bradford 19, Edinburgh 20, Norwich 21, Birmingham 21, Plymouth 22, Hull 23, Brighton, 23, Leicester 23, Bristol 23, London 23, Glasgow 23, Manchester 24, Leeds 26, Sunderland 26, Salford 27, Oldham, 28, Wolverhampton 30, Liverpool 30, Nottingham 30, and Dublin 36.

### Longevity of Medical Men.

In a retrospect of the past year, the *Daily Telegraph* comments upon the longevity of members of the profession ; adducing many past as well as living evidences in proof, especially among men of more than ordinary capacity and intellectual attainments. Of those still present in the flesh are :—Archibald Billing, M.D., F.R.S., who for the last sixty years has resided in London, and completed his ninetieth year on the 10th inst. ; Joseph Hurlock, F.R.C.P., of Brighton, is eighty-eight ; Sir Thomas Watson, Bart., M.D., F.R.S., eighty-eight ; Alexander Tweedie, F.R.S., F.R.C.P., eighty-six ; James Arthur Wilson, F.R.C.P., of Holmwood, near Dorking, eighty-five ; Bisset Hawkins, F.R.S., F.R.C.P., eighty-four ; Sir James Alderson, F.R.S., late President of the Royal College of Physicians, eighty ; Christopher J. R. Allatt, F.R.C.P., of Dover, eighty ; Sir George Burrows, Bart., F.R.S., D.C.L., late President of the Royal College of Physicians, seventy-nine ; James Muscroft, F.R.C.S., of Pontefract ; ninety-five ; T. M. Greenhow, F.R.C.S., of Leeds, ninety ; Robert Tayler, F.R.C.S., of Brighton, ninety-one ; James Moncrieff Arnott, F.R.S., late President of the Royal College of Surgeons of England, eighty-seven ; John Flint South, F.R.C.S., of Blackheath, eighty-four ; Cæsar Henry Hawkins, F.R.S., F.R.C.S., Serjeant Surgeon to the Queen, of Grosvenor Street, eighty-three ; James Luke, F.R.S., F.R.C.S., Consulting Surgeon to the London Hospital, eighty-three ; Robert M'Cormick, R.N., F.R.C.S., Deputy Inspector of Hospitals and Fleets, eighty-three—this gentleman accompanied Sir Edward Parry as Assistant Surgeon in Her Majesty's ship *Hecla* in the attempt to reach the North Pole in 1827.

### The Medical Register, 1880.

OUR attention has been called to the fact that several persons registered in the year 1879 have not as yet applied for the copy of the Medical Register, to which they are entitled. We understand that everyone who was registered in that year, will, on sending the order for the book, duly signed, to the Registrar for the division of the Kingdom in which he has been registered, together with twelve penny stamps to cover postage, the copy for 1880 containing his name will be sent by post.

### The Threatened Epidemic of Small-pox.

LONDON is apparently once again threatened with an epidemic of small-pox ; the disease is described as marching on the metropolis from the south-east, and as being sporadically present in the south-west, and districts apparently unconnected with each other. It has been the custom for some years back to attribute the origin of small-pox, as of other zymotic diseases, to such causes as filth, fermentation, specific poison, and so on, its propagation to contagion. We should be glad to have the views regarding the present outbreak of those who would thus account for the large class of diseases, of which small-pox is one. As a matter of fact, the recurrence of small-pox, typhus fever, and some other diseases, takes place at regular intervals of time, and as far as we are able to see, without any difference in conditions as regards filth, or rather cleanliness of places on such occasions from what prevails during its absence. Communication between persons is no greater during its

presence than while small-pox is absent ; if, therefore, the extension of an epidemic depends upon contagion alone, how are we to account for its cessation after having prevailed in a locality for a certain defined time. These, and kindred questions bearing upon epidemiology, are perhaps easier put than answered.

### Perfumed Carbolic Acid.

PERFUMED carbolic acid is prepared from carbolic acid 1 part, oil of lemon 3 parts, alcohol 36 degrees 100 parts, mixed. This mixture, which appears to be quite stable, and has only the odour of lemon, is what has been known as "Lebon's perfumed carbolic acid," the formula of which has long been a secret, but has now been made known in the *Moniteur Scientifique* of Paris. The antiseptic properties are in no way affected by the oil of lemon.

### The Metropolitan Hospital Saturday Fund.

AT the annual meeting of the Metropolitan Hospital Saturday Fund, held at the Charing Cross Hospital, on Saturday last, the report showed that the 1880 collection exceeded that for the previous year by £452—£5,208 having been collected in workshops, and £1,398 in the streets, on Hospital Saturday, giving a total of £6,604. There is one feature in the present management we would congratulate the Council upon—that is the reduction of expenses, from 29'81 in 1874 to 14'73 in 1880. Six years ago we protested against the scarlet liveries, flags, banners, and other absurd and extravagant adjuncts of the self-elected managers of the fund. Now all is changed. Few, if any, of the mimics of a circus-show have aught to do with the matter ; the expenditure has been reduced by more than 50 per cent., and both collection and distribution is controlled by men possessing a little common sense.

### A Fasting Woman in Ipswich.

THE following extraordinary tale is vouched for, on good authority, by a correspondent :—There exists—I cannot say lives—in a small by-way bordering on Upper Orwell Street, a poor woman, who subsists without partaking of any kind of food. It is not long since that the good people of Ipswich were excited over the exploits of the notorious Dr. Tanner, three thousand miles away, little dreaming that in their own town, close to their own homes, was a person whose fast puts that of the American starver entirely in the shade. The Ipswich faster has taken a fast, perforce, of between two and three years, whilst the Yankee's was a voluntary one of less than six weeks.

This woman is the wife of a jobbing gardener, named John Lockwood. Seven years ago she became ill, and was twice admitted to the East Suffolk Hospital, and was discharged from that institution as incurably afflicted. From that time she had less and less inclination for food, and for the last two years has not swallowed a piece of bread. Until about three months ago, she is said to have subsisted entirely on small portions of the hard-boiled yolk of an egg, at the rate of less than an egg a fortnight. The aggregate weight of the solid food eaten during 1880 would not amount to more than a pound. Previously, she was sustained upon a boiled potato. Since September

she has partaken of nothing but a few drops of weak tea, with which she moistens her mouth. In the early part of the year she refused her customary piece of egg for several days, and was considered to be dying; her eyes remained closed, and respiration apparently ceased. Her friends, however, were able to detect her breath on a glass. In this state of coma she remained for nine days. Since then she has been in a similar state for more than a fortnight at a time, faints with the least excitement, and will not regain her normal condition for hours, or perhaps days. To call attention to herself, she sometimes sighs deeply; but beyond this, not a sound escapes her. She appears, however, to possess her mental faculties. An Ipswich medical man who has visited Mrs. Lockwood states that she is suffering from brain-pressure, for at times she endures intense pain in the region of the right temple. When suffering most, the nervous tremour can be distinctly felt by laying one's hand on her forehead, and the throbbing soon becomes so violent as to cause her to relapse into insensibility, from which condition she recovers in about twenty-four hours. One thing is certain—the prolongation of life in her case is an extraordinary occurrence, and a phenomenon which deserves the attention of the profession. The woman is said to be able to think, and, as far as her strength allows her, to act in an intelligent manner.

In the principal foreign cities the rates of mortality, according to the most recent weekly returns, were in Calcutta 41, Bombay 30, Madras 39; Paris 26; Geneva 16; Brussels 21; Amsterdam 23, Rotterdam 22, The Hague 24; Copenhagen 23; Stockholm 31; Christiania 11; St. Petersburg 38; Berlin 21, Hamburg 26, Dresden 21, Breslau, 23, Munich 25; Vienna 28; Buda-Pesth 36; Rome 30, Turin 25, Venice 26; Alexandria 41; New York 32, Brooklyn 23, Philadelphia 23, and Baltimore 24 per 1,000. Small-pox caused the same number of deaths in Rome as in London—viz., 17, and 14 in Paris.

ST. MARY'S HOSPITAL, Paddington, comes in for the munificent legacy of £25,000 by the will of Mr. Stanford, F.R.S., who died about a month since. This sum is to be devoted to the building of a wing to the memory of his mother, Mrs. Mary Stanford, and to bear her name.

MR. LUTHER HOLDEN, F.R.S., late President of the Royal College of Surgeons of England, has been elected consulting surgeon to St. Bartholomew's Hospital, on resigning as surgeon.

A NEW title has been introduced in the Faculty of Arts at Edinburgh University, which gives the style of "Literate of Arts" to undergraduates after attending certain classes for two years and passing certain examinations.

A PAPER is announced for reading at the Society of Arts, on "A Sanitary Protection Association for London," by Professor Fleeming Jenkin, F.R.S. Professor Huxley will preside.

Among the notices given in the House of Commons

on the opening of the Session was one for "The Repeal of the Contagious Diseases Act," by Mr. Stansfeld.

MR. PETER TAYLOR also gave notice of a "Resolution to amend the present law in regard to Compulsory Vaccination," which was unjust.

MR. E. D. GRAY gave notice of a Bill for the better codification of the sanitary authorities in Ireland, so as to prevent the spread of dangerous and infectious diseases.

MR. CHAPLIN proposes to call attention to the serious outbreak of foot and mouth disease which had recently occurred in many parts of England, and to move a resolution.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

UNIVERSITY OF EDINBURGH.—The matriculation returns for the past year (1880) have just been made up, and show a very satisfactory increase over the returns for 1879. The aggregate number of students who matriculated during the year was 3,172, being an increase of 316 on the previous register. In the Faculty of Medicine the number was 1,634. In this Faculty the gradually increasing ratio is probably due in a great measure to the continued wide range of supply of students to which India, the Colonies, and even foreign countries highly contribute. The entries in the register show that of 1,634 students in the Faculty of Medicine, 679 were from Scotland, 558 from England, 28 from Ireland, 112 from India, 204 from the different British Colonies, and 53 from foreign countries. The late Andrew Vans Dunlop, M.D., bequeathed the residue of his estate, probably amounting to between £60,000 and £70,000 (of which £45,000 has been received), for the purpose of founding 18 scholarships in the University, of the annual value of about £100 each, tenable for three years, to be termed "The Vans Dunlop Scholarships." The first six of these Scholarships were to be devoted to the Faculty of Medicine—the first for the subjects of the preliminary examination, the second for botany, zoology, chemistry, and anatomy, the third for physiology and surgery, and the remaining three for the subjects of anatomy, physiology, materia medica, and pathology. The remaining twelve scholarships specified by Dr. Vans Dunlop's will are to be attached to the Faculty of Arts. They are now before the Senatus Academicus in order that regulations may be arranged and the scholarships be open for competition at an early date, of which due notice will be given.

TRINITY COLLEGE, EDINBURGH.—Dr. Dunsmore, jun., has been elected medical officer of the College, *vice* Dr. Inglis resigned.

A HOSPITAL FOR LARGS.—At a meeting held on the 6th inst., of the joint committee for the parish and burgh of Largs, a letter was read from Mr. John Clark, of Carlinghall, offering to erect a hospital at his own expense. The offer was unanimously accepted.

COURT MEDICAL APPOINTMENT OF AN ABERDEEN GRADUATE.—We learn that by appointment of Her Majesty, Dr. James Law, London, a graduate of the University of Aberdeen, has become physician in attendance at the Court, and that he will at once enter on his duties in succession to Dr. Marshall.

**ABERDEEN—MEDICAL OFFICERSHIP OF HEALTH.**—This appointment, we learn, is at present vacant. In these times it is hardly requisite that we should urge the importance of such an appointment in a city of the pretensions of Aberdeen, and the expediency of appointing to the office a gentleman of high professional standing. In order to the more efficient discharge of the duties pertaining to the position, Aberdeen should follow in the wake of most other cities of equal importance, and elect a gentleman, at a proper salary, to devote his whole time and attention thereto. We understand that this is the view entertained by Dr. Beveridge, and we hope that the Committee of the Town Council to which we believe the matter has been relegated, will adopt the same enlightened view. Sanitary science possesses a special charm for many enlightened practitioners of medicine; it is closely associated with medical police and jurisprudence, and should Aberdeen offer sufficient inducement to well-known junior practitioners of medicine, we believe that an excellent selection could be made, and the community thus greatly benefited. The last medical officer of health received £50 per annum.

**REGISTRAR-GENERAL'S RETURNS.**—According to the official returns in the eight principal towns of Scotland for the week ending Saturday, the 1st inst., the death-rate was 22·5 per 1,000 of estimated population. This rate is 2·6 under that for the last week of 1879, but 1·7 above that for the week immediately preceding. The lowest mortality was recorded in Paisley, viz., 19·1 per 1,000; and the highest in Leith, viz., 25·8 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3·7 per 1,000, exactly the same as for the previous week. Scarletina was again the most fatal, and caused 12 deaths in Edinburgh. Acute diseases of the chest caused 141 deaths, being an increase of 17 on the number for last week. The mean temperature was 32·6, being 1·5 below that for the week immediately preceding, and 7·1 below that for the last week of 1879.

**ST. ANDREW'S UNIVERSITY.**—We understand that Sir Theodore Martin has postponed the delivery of his address as Lord Rector of the University of St. Andrews till the beginning of next session. He will probably then be in a position to refer more definitely to the prospects of the University in connection with recent important movements affecting its interests. Mr. John Skelton has been appointed as the Rector's assessor in the University Court.

**EDINBURGH ROYAL INFIRMARY.**—A general meeting of the contributors to this Institution was held on the 3rd inst. in the Council Chambers. The Lord Provost presided. From the Annual Report, which was presented, we glean that there have been received during the past year:—Legacies and donations of £100 and upwards for the Infirmary, to the extent of £18,255 18s. 6d.; out of which had to be met excess of ordinary expenditure for Infirmary, including fever hospital (£27,818 11s. 4d.), beyond ordinary receipts (£21,540 14s. 2d.), £6,277 17s. 2d. Deducting this sum of £6,277 17s. 2d. from the legacies and donations received, there remained to be added to capital a balance for the year of £11,978 1s. 4d. The ordinary income for the year was shown to be—£21,540 14s. 2d., as compared with £18,699 6s. 3d. for the preceding year—being an increase of £2,841 7s. 11d. This increase is the more gratifying and encouraging, as, notwithstanding the general depression during the year, all the ordinary sources of income had improved. The largest increase has arisen from students' fees. These for the year amounted to £4,179 8s., while for the preceding year they were £2,643 13s., showing an increase of £1,535 15s. After the reading of the Report, last year's Committee of Managers was re-elected, and the meeting ended.

## IRISH POOR-LAW MEDICAL SUPER-ANNUATION.

WE remind our readers that a most important general meeting of the Irish Medical Association will be held on Saturday next at the Royal College of Surgeons, Dublin, to consider the whole question of Poor-law superannuation in Ireland. This subject is perhaps *the* topic of most direct interest to the Irish provincial surgeon in the whole arena of medical politics, and it has engrossed much of the attention of the Executive Committee of the Association for several years. It is, in truth, one of the most knotty points with which that Association has had to deal, because of the great difficulty of reconciling the just claims of the Poor-law medical officers, with the possibilities of legislation, and with the reasonable business precautions upon which Government departments insist. We know exactly what the Poor-law medical officers would wish the law to be. They would desire that they should be entitled to claim two-thirds of their full salaries and emoluments, when no longer able to fulfil their duty. They would desire that the guardians should have no power to refuse or curtail this pension, and they think it would be well that the superannuation should be paid out of the consolidated fund, and not out of the rates. Furthermore, they think it reasonable that they should be entitled to a pension of reasonable amount on retirement at any time, whether they be capable of duty or not, as all civil servants are. We do not say that any of these requirements are unreasonable as a matter of equity; but we believe we ought to at once make it understood that, in the aggregate, they are absolutely hopeless of realisation, and that the certain effect of an unbending demand for all these things would be the rejection of Poor-law superannuation for years to come.

The first question is whether the grant of a pension can under any circumstances be made compulsory, and here we are met by the assertion of the principle that those who pay should have power over what they pay. It will be said that if the pension were to be paid by Government then it would be reasonable that the guardians should have nothing to say to it; but as it is paid out of the rates, they should have full power over the sum to be granted. This argument, we venture to hope, may be got over by showing that the whole principle of local government is that the central authority, *i.e.*, the Local Government Board, shall have control over all payments by the guardians, and that as it is the duty of the central authority to see that the money of the ratepayers is fairly expended by the guardians, so it becomes their duty to see that incapable officers are not retained, and that when dispensed with they are fairly treated. The aspirations of the Irish Poor-law medical officer is surely not unreasonable. Speaking generally, he does not seek a respite from his unremitting, laborious, and uninteresting duties until he is truly incapable of his work, and when that moment comes he asks only to be granted what is fair under his own particular circumstances. But this favour he may not receive as long as—under the existing law—his future is at the uncontrolled discretion of the guardians, and he therefore urges that the question shall be decided not by a local clique of third-class *gaubeens*, whose chief desire is to save their pockets, but by a central department which

has no interest save in seeing right done, and securing the efficiency of the service. The clause of the Medical Charities Bill, introduced last year by the Irish Medical Association, is as follows :—

Be it enacted that whensoever it shall appear to the Local Government Board for Ireland, upon the memorial of such officer, or upon other information, that any officer of a union in Ireland is incapable of effectively discharging his duty in either capacity by reason of old age, such age exceeding sixty years, or from infirmity, or ill-health of mind or of body, the said Board shall require such medical officer to submit himself to a medical board for the purpose of examination. Such medical examining board shall consist of the medical commissioner of the Local Government Board for the time being, together with two other registered medical practitioners in actual practice nominated by said Board, but not holding any other office under said Board, and it shall be their duty to decide by examination of said officer, and upon consideration of the nature and extent of his duties as union officer, or as dispensary medical officer, or other office held by him in virtue thereof, whether he is incapacitated from the effectual discharge of his duties in all or any of said offices by reason of the causes aforesaid; and if upon report of the said medical examining board it shall appear to the Local Government Board that the said medical officer is so incapacitated, the Local Government Board shall direct that he shall cease to hold all or any of said offices; and he shall be thereupon held to have vacated such offices; and the Local Government Board, upon consideration of the age and length of service of said officer, and the nature and extent of his duties therein, and all other circumstances bearing thereon, shall grant to such officer, notwithstanding that he shall not have devoted his whole time in respect of each of the offices from which he may be thus removed, a yearly allowance not exceeding two-thirds of entire amount of all salaries, fees, and emoluments received by him in respect of the functions discharged by him as union officer or in connection therewith. Such allowance shall be paid to said medical officer for the term of his natural life by the board of guardians of the union in which he may have held such offices, and shall be charged as previously paid; and such allowance shall be payable to or in trust for such officer only, and shall not be assignable nor chargeable with his debts or other liabilities.

This clause was resisted in the House of Commons by Major Nolan, M.P., and Mr. Macartney, M.P., as being calculated to increase taxation; and we fear it may be objected to also by the Irish Local Government Board, because it throws upon that department the duty of assessing the amount of pension, and might thus bring them into controversy with the Board of Guardians, by whom the pension was to be paid. Nevertheless, some such enactment will be absolutely necessary to meet the case of a medical officer who breaks down after a comparatively short service, and who would not be entitled, on the Civil Service scale, to anything but a pittance.

To be placed on the footing of Civil servants in the matter of pension has long been regarded by Poor-law medical officers as the panacea for their superannuation grievances; but it is necessary to point out that such a concession, *per se*, would be but a doubtful gain. A Civil servant is entitled to pension at the rate of one-sixth of his salary for each year of service, and after a certain length of service is entitled to retire when he pleases. Thus a dispensary medical officer taking office at 23 years of age should serve 40 years—*i.e.*, until he was over 63 years of age—before he could possibly receive as pension two-thirds of his emoluments. Thus, if the privilege of becoming Civil servants were placed to-morrow before the Poor-law medical officers, they would have to choose between a certainty of one-sixth for each year served and a possibility of two-thirds of their emoluments granted at any period of

service. No doubt the senior officers who have served close upon 40 years would prefer the certainty of the Civil Service rate, while the junior officers might rather stand their chance of a discretionary two-thirds.

But this matter will be looked at by Parliament not in the interest of the medical officer alone, but from the point of view of what is fair to all parties.

We hope we are not counting too much upon the just feeling of the Government and the House of Commons when we say that we believe that the Civil Service pension as a matter of right may be attainable, if judgment be exercised and perseverance given to the subject. By a circular which we published last week the English Local Government Board has—to a certain extent—recognised the fairness of this assessment of pension. The Board expressed its intention to make the Civil Service scale the standard which—in ordinary cases—it will sanction, but, inasmuch as the medical officer does not devote his whole time to the service, and is not paid in the same proportion as the other union officers, it will calculate the pension which may be sanctioned by adding ten years to the actual service. This seems to us a fair business-like proposition, and, on the whole, we consider that it will be wise for Poor-law medical officers to accept such a scale of superannuation.

We may hope that, if a Bill be promoted by the Poor-law medical officers of the United Kingdom, to secure the Civil Service rate, with a clause giving power to the Local Government Board to increase the grant in exceptional cases, such a Bill will be acceptable to heads of departments, and may pass Parliament. We desire to look at this question from a statesman's point of view—not to ask what is unreasonable or unworkable, and we fully believe that, in this as in other legislative questions, it is bad policy to clamour for anything which cannot be conceded with due regard to what is equitable.

#### DUBLIN SANITARY ASSOCIATION.

THE annual meeting of the above association was held on the 5th inst.

Mr. Jonathan Pim, President of the society, presided.

**WATER SUPPLY.**—Your committee, while believing that the Vartry water, if properly filtered through sand beds, changed at suitable intervals, is an excellent water supply, strongly recommended that the analysis of the water should be made every month under the direction of the Local Government Board, by an analyst not officially connected with the Corporation, and the results published in the Registrar General's returns as in London. It will be seen from the evidence of Mr. Price, C.E., that avoidable impurities have been found in the Vartry water; and the Corporation, being in the position of a public water company, supplying water for profit—as they do to the outlying townships of Pembroke, Kingstown, Clontarf, &c.—it is but reasonable that independent information as to the proper filtering of that water should be afforded to the public of Dublin.

**BATHS, &c.**—“The bath and wash-house accommodation provided for the working classes is very inadequate. The requirements of such institutions are described by Mr. Rawlinson. Baths and wash-houses for the working classes should not necessarily be fine-looking architectural buildings placed on imposing sites for the sake of appearance, to which neither working men nor their families resort for several reasons. The distances from their houses may be too great, the charges too high, and the imposing

look of the places may also be, to the poor, forbidding. Baths and wash-houses should be in the immediate districts of the poor; they cannot be too plain in appearance if they are sufficient in strength; they cannot be too simple in their arrangements if they are calculated to be useful. Wash-houses, such as we have here indicated, will afford almost as useful accommodation to the working man as adding an additional room to each cottage or tenement. There are open spaces in Dublin which we have inspected admirably situate for such uses if they are made available."

Dr. JOHNSTON (president of the College of Physicians) moved the adoption of the report. He said the College of Physicians and the College of Surgeons were both in thorough accord with the movement of the Sanitary Association.

Mr. WIGHAM seconded the motion. The tenement houses were well described by the Commissioners as the "sanitary sore" and cause of the high death-rate of Dublin. The Commissioners spoke of the horrible room tenements which exist in almost every part of the city, and the terrible injury they caused to the whole community, but more especially to the hundred thousand citizens who occupied them. There was a great deal too much laxity shown by the sanitary authorities in dealing with tenement houses. He happened to be, with others, the owner of several houses of the tenement class, but although he and the other persons associated with him were the owners of the houses, they had no control over their management. Before the property came into their hands a lease existed, and the owner of the lease managed the property, which was about as disgusting a place as a person could go into. The picture drawn by the Sanitary Commissioners of some of the tenement houses was not a bit overdrawn. A large number of families were crowded into one house, which was probably intended only for one or two families. He regarded the present state of things as deplorable. There ought to be some power to compel the closing up of such houses; they should be condemned by the sanitary authorities, and people should not be allowed to live in them. If that could be done the middle men who make such large sums of money out of the miserable lodgings of their poorer fellow citizens could not carry on their objectionable trade any longer, and the houses would fall, probably, into the hands of the owners, whose interest it would be to rebuild them, and make them fit for the working classes to reside in (hear, hear). Instead of containing dubious statements, he thought the report should have candidly told them that the sanitary authorities were slow to take action in these matters. The Corporation spent a large sum of money in paving and keeping the streets in order, but seemed to forget in some measure that a grave danger existed in the state of the public sewers. Then with regard to the infectious disease, he was strongly of opinion that infection was spread at dispensaries owing to the bad and insufficient accommodation provided there (hear, hear). The people were crowded together in the most objectionable way, and he thought attention should be called to the matter, and better accommodation should, if possible, be provided (hear, hear).

The CHAIRMAN, before putting the resolution, said he was glad to know that the meeting of the Social Science Congress would be held this year in Dublin, inasmuch as it would afford them an opportunity for bringing forward and discussing various questions of public importance. The difference existing between England and Ireland as regards the poor laws and outdoor relief was a question that should claim their attention. In England a man in straitened circumstances can tide over the difficulty by getting a little outdoor relief; and in Dublin he could get no assistance unless he went into the workhouse, a thing that most men were naturally unwilling to do. And the poor man in Dublin was living in one of those wretched ill-drained tenements which had been fitly described as the fruitful source of fever and disease. They almost invariably found that when a large number of people were out

of work there was an increase in the number of people who were obliged to go to hospital. In Scotland the governing authorities in towns have the power to interfere with reference to houses that have become dilapidated; and in cases of doubtful title, where the occupier expends money in improving the premises, his expenditure is registered, and he becomes a mortgagee against the premises, and must be paid off by anyone coming forward to establish title.

Mr. MELDON, M.P., in seconding the motion, said the public mind required to be educated on the question of sanitary reform.

The motion was adopted.

The hon. the RECORDER moved the following resolution:—

This meeting desires to express its satisfaction that the inquiry held by the recent Royal Sanitary Commission was of so searching and comprehensive a character; and that its result bears out so fully the necessity for the measures urged from time to time by the Association, and trusts that the public interest thereby excited in the subject of the sanitary state of Dublin will be maintained, and the recommendations of the Commission energetically carried into effect by the sanitary authorities.

The great question in Dublin was the state of the tenement houses. No doubt a great deal of work had been done by the existing authorities. The late Lord Mayor, Mr. Gray, was the first to take up the subject of the Artisans' Dwelling Act of 1875—a large and ambitious act, which proposed the taking down of enormous areas of houses, and the building of others in their places. Five years ago twelve areas were condemned by Dr. Mapother. Only one of these had yet been cleared, and the first stone of the first building upon it was only laid by the Lord Lieutenant the other day. If they only went at that rate they would never get rid of the evil. Mr. Gray had called attention to one difficulty—namely, that of providing residences for the people whose houses were taken. But he (the Recorder) thought the Act of 1875 was too ambitious. Why not try to utilise the buildings they had and make them better? Their fellow citizen, Mr. Vance, had done this with effect, and had made excellent accommodation for a number of families. And before they railed at the Imperial Legislature for not providing for the wants of the people, they should look to what had been done. In 1868 a statute was passed called the Artisans' Dwelling Act. It actually provided—as was the case in the Scotch boroughs—that rent charges and mortgages might be granted for securing the cost of repairs done to houses in an unsanitary condition. But it required all the owners to be brought together; and the sanitary authority was entrusted with the power of granting the mortgages. Now, without in the least disparaging them, he did not think the sanitary authorities would be at all competent to deal with the complications of title that would arise in such cases. There was an appeal to him, but he had never had any case of the kind before him. He did not think the Act workable as it stood; but it could be made so by giving the power of granting mortgages to some suitable tribunal. An Act passed in 1866, called the Labourers' Lodgings Act, was, in his opinion, workable. It gave the Corporation power to build on their own ground, or to buy plots of ground for the purpose of building on them. So that under that Act they could by degrees build labourers' dwellings. There was a provision that the Corporation could borrow money from the Board of Works. Mr. Gray had said very fairly that the townships ought to help to pay for those improvements. He (the Recorder) could understand the people of Rathmines and Pembroke townships not wishing to be brought into the Corporation; but he did not think they would object to pay a share of the cost of settling the tenement houses question. He did not see why, under the Act of 1878, sections 11 to 14, those townships could not be united for sanitary purposes under a joint board: and if they got on well in that way it might lead to a union with the city.

After adoption of some formal resolutions, the meeting adjourned.

## Obituary.

### CHRISTOPHER FLEMING, M.D., F.R.C.S.I.

With very much regret to announce the death of Mr. Christopher Fleming, who for many years filled a prominent position in the surgical profession in Dublin. He had for some years retired from active work, and lived in retirement at 15 Brookfield Terrace, Donnybrook, where he died on the 31st of December, 1880, in his 81st year.

Mr. Fleming was apprenticed to the younger Dease, and on his master's death was transferred to the charge of the late Abraham Collea, under whom he finished his studies. He became a member of the Royal College of Surgeons, Ireland, in 1826, and graduated as A.M. and M.D. in the University of Dublin, in 1838. He was appointed surgeon to the Netterville Dispensary in Blackhall Street, and entered upon private practice; but it was not until he had nearly reached his fiftieth year that he succeeded in obtaining a hospital appointment. He was then made surgeon to the Richmond Surgical Hospital, and held the office for about 18 years. He also became consulting surgeon to Steven's Hospital, and held that office, as well as a seat on the board, until the time of his death. He was a Member of the Royal Irish Academy; President of the Royal College of Surgeons, 1859-60; President of the Pathological Society, 1860-61; Chairman of the Surgical Court of Examiners, Royal College of Surgeons, Ireland, for several years; Corresponding Member of the Surgical Society of Paris; Lecturer on Surgery in the Old Park Street School of Medicine; an Examiner in the same subject in the Queen's University, Ireland; and a Member of the Board of Superintendence of Dublin hospitals.

Mr. Fleming, although he succeeded to his hospital so late in life, set his class an example of industry and enthusiasm which made him one of the most popular teachers. He was a most careful and sagacious surgeon, and especially in dealing with diseases of the genito-urinary organs he exhibited the highest skill in diagnosis, and manipulative dexterity which was remarkable. His pupils were always his admirers, and they still bear the memory of his personal kindness, and of the example of careful observation which he set them. He was a frequent contributor to the periodical journals; among his best known papers being those on Abscesses of the Pharynx in Children and Adults. His writing upon questions of the sexual organs were very voluminous; and he became known as a leading authority upon this branch, with the result of enjoying for several years a very large and lucrative practice in it. Towards the close of his life he issued, in conjunction with Mr. W. Thomson, a volume which included much that he had already written on these affections, and it was received as a work of high merit and of great practical value to the surgeon.

During the later years of his life, when strength was failing, he still liked to recall the pleasant associations he had with his pupils, whose progress, so far as possible, he watched with some pride; and we are sure that to those of them who read this announcement, there will come deep regret for the loss of one who above all things desired to be regarded as their friend.

## Medical News.

**Harveian Society of London.**—The following list of names of gentlemen elected as officers of the Society for the year 1881:—*President:* Henry Power, F.R.C.S. *Vice-Presidents:* F. J. Gant, F.R.C.S., W. H. Day, M.D., \*J. Milner Fothergill, M.D., \*H. Sewill, M.R.C.S. *Treasurer:* James E. Pollock, M.D. *Hon. Secretaries:* George P. Field, M.R.C.S., \*Malcolm Morris, F.R.C.S. *Ed. Council:* G. C. P. Murray, M.D., W. Squire, M.D., G. Danford Thomas, M.D., J. W. Langmore, M.D., \*T. T. Whigham, M.D., \*Alfred Cooper, F.R.C.S., \*J. F. Payne, M.B., \*F. A. Mahomed, M.D., \*Osman Vincent, F.R.C.S. *Ed.*, \*Robert Argles, L.R.C.P., \*W. Towers Smith, M.R.C.S., \*W. Reynier, M.R.C.S. An asterisk is prefixed to the names of those gentlemen who did not hold the same office in the preceding year.

**University of Durham.**—Examinations in medicine and

surgery 6th, 7th, 8th, 9th, and 10th December, 1880. The following satisfied the examiners, and had their respective degrees conferred on December 14th. *For the Degree of Doctor in Medicine:* Edric Selous, M.R.C.S., Walter Lattey, L.R.C.P., John Balton Emerson, M.B., M.R.C.S., Bedford Fenwick, M.B., M.R.C.S. *For the Degree of Bachelor in Medicine:* Thomas George Ainsley, M.R.C.S., Thomas Dutton, L.R.C.P., Alexander William Woodman Dowding, L.R.C.P., M.R.C.S., L.S.A., Thomas Coke Squance, George Lucas Pardington, L.R.C.P., M.R.C.S. *For the Degree of Master in Surgery:* Alexander William Woodman Dowding, L.R.C.P., &c., Thomas Coke Squance. *Examiners:* Chas. Gibson, M.D., Chas. John Gibb, M.D., G. H. Philipson, M.A., M.D., F.R.C.P., Luke Armstrong, M.D., M.R.C.S., Henry E. Armstrong, M.R.C.S., Frederick Page, M.D., T. W. Barron, M.A., M.B., J. S. Bristowe, M.D. *Lond.*, F.R.C.P., Reginald Harrison, F.R.C.S. E.

**RESULTS OF MARRIAGES WITH IDIOTS.**—Dr. Berkhan, in the *Zeit. für Psych.*, vol. 37, making some interesting observations as to the capabilities of microcephalic and other idiots to propagate their species. A semi-idiotic man has been married for some years to a healthy woman, there is no family. A healthy man, married to an idiotic wife, has had three children by her, two of them are idiots. These cases support Vogt's view, that while female idiots may bear children, the males are very frequently incapable of begetting them. Marriages are very rare between male half-cretins and healthy women, but are not uncommon between healthy men and semi-cretinous females who may happen to own a little property. The author has never seen the progeny of these marriages arrive at maturity; if not still-born, the children usually die during childhood.

## NOTICES TO CORRESPONDENTS.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**CORRESPONDENCE.**—The letters of Dr. C. A. Cameron, Dr. John Martin, Dr. T. W. Morris, and Dr. T. M. Sunter are unavoidably held over to our next.

**A DISPENSARY DOCTOR.**—The *Australian Medical Journal* is obtainable in this country of Messrs. Gordon & Gotch, Colonial Newsagents, Bride Street, London, E.C.

MR. NORMAN COWOLLY is thanked for his translation of Prof. Snell's paper "On Simulated Insanity," which is marked for early insertion.

DR. C. W. MCCARTHY. — "Observations on Skin Grafting" will appear during the present month.

MR. WALLER would doubtless be able to obtain the desired information on application to the Secretary.

**AN OBJECTION.**—The practice is highly reprehensible, and owing to the admission of so many into the ranks of the profession of those who can hardly be expected to have "the feelings of gentlemen" is, we fear, on the increase in all large towns. If they are beyond the pale of the moral law the law of the land cannot touch them so long as their practice is kept within legal bounds.

**TAMAR INDIAN.**—Dr. Bumstead of New York, ascertained from the manufacturer in Paris that this preparation was mainly powdered senna leaves mixed with an agreeable confection.—*New Remedies.*

MR. T. M. DOLAN, F.R.C.S., Halifax.—Your papers on "Ophthalmia in Workhouse Schools" and on "The Prophylaxis of Eables and Hydrophobia" are marked for early insertion.

DR. BERRY, Wigan, is thanked for his "Notes of a Case of Hydrophobia," to which space will shortly be given.

### SUBURBAN CEMETERIES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The danger to the public health arising from our overcrowded suburban cemeteries can scarcely admit of exaggeration. Since Mr. Seymour Haden's eloquent letters on "Earth-to-Earth" burial appeared in the *Times* the attention of the authorities and of the public (whom it most concerns) has been again and again drawn to the evil

natives of interest in neighbourhoods thickly populated. Nothing, however, has been done. Notes of warning have been uttered in vain, while even the Government inspectors of grave-grounds have strongly urged that action should be taken in the matter. Certain of the metropolitan cemeteries are perfectly unsuited for the purpose of burial owing to the unfitness of the soil. This circumstance, added to the overcrowding of bodies in circumscribed places, must end calamitously if the practice be not checked. Our suburban cemeteries, like the old churchyards of London, are, to use the language of Mr. Chadwick, likely to become "the plague-spots of its population."

Surely there is no lack of places some miles distant, but yet readily reached, out of this teeming city wherein the dead can find meet sepulture. Woking Cemetery alone, on Mr. Haden's showing, on the principle even of giving a separate grave to each body, is owing to its dimensions, capable of meeting the annual mortality of greater London for all time to come. Besides, it possesses advantages of a suitable soil, salubrity, extent, picturesque, and isolation. So far it resembles the cemeteries of Mount Auburn, Laurel Hill, and Greenwood in the United States which are renowned for their spaciousness and attractiveness. Your obedient servant,

SANITARIAN.

**GERMAN THERAPEUTICS.**—In a recent issue we chronicled the fact "that thirty-eight out of ninety-five extraordinary students (foreigners) of the University of Vienna, during the last summer session, were Americans." In quoting this paragraph from our column the *Louisville Medical News* pertinently adds:—"And what a vast amount of bad therapeutics they will bring home!" What will our German saints in medicine think of this view of their training on the other side of the Atlantic?

**CLINICAL SOCIETY.**—Friday, Jan. 14, Annual Meeting.—Election of Officers.—Report on "The Treatment of Hip Disease, with especial reference to the Operation of Excision."—Mr. Croft, "On a Case of Traumatic Hydrocephalus."—Dr. E. H. Lloyd, "On Two Cases of Myxœdema."—Dr. Sutherland, "On a Case of Chronic Vomiting in which no Food, except Kermes, was taken for Sixteen Months."

## VACANCIES.

- Barnsbury Dispensary.**—Medical Officer. Salary, £120. Election, Jan. 17.
- Braintree Union.**—Medical Officer of Health. Salary, £150. Applications to the Clerk of the Union, Braintree, Essex, before Jan. 22.
- Brighton and Hove Dispensary.**—Resident House Surgeon. Salary, £140. Applications to the Hon. Sec., Queen's Road, Brighton, by Jan. 31.
- City of Dublin Hospital.**—House Surgeon. Salary, £100. Applications to the Secretary of the Medical Board before Jan. 26. (See Advt.)
- Dromore Dispensary.**—Medical Officer. Salary, £115. Election, Jan. 20.
- Dunmanway Dispensary.**—Medical Officer. Salary, £140. Election, Jan. 25.
- Hospital for Epilepsy and Paralysis, Regent's Park, N.W.**—Assistant Physician. Applications, with testimonials, to the Secretary, before Jan. 19.
- Manchester Royal Infirmary.**—Resident Medical Officer. Salary, £150, with board. Applications, with testimonials, to the Chairman by Jan. 22.
- West London Hospital.**—Assistant Physician. Honorary. Application to the Secretary on or before Jan. 21.

## APPOINTMENTS.

- BENTHALL, W., M.R.C.S.E.,** House Surgeon to the Derbyshire General Infirmary.
- EVERARD, H. N., M.B.,** House Surgeon and Apothecary to the Leicester Infirmary and Fever Hospital.
- HOOPER, C., M.R.C.S.E.,** Medical Officer of Health to the Aylesbury Rural Sanitary Authority.
- HYLTON, J., M.B., G.M.,** Assistant Physician to the Royal Edinburgh Asylum, Morristown.
- LONGWOOD, H., L.K.Q.C.P.I., L.R.C.S.I.,** Medical Officer to the Thirsk District and the Workhouse of the Thirsk Union.
- PADDISON, E. H., M.B.,** a Junior Assistant Medical Officer to the Surrey County Lunatic Asylum.
- PATON, C.A., M.R.C.S.E.,** Medical Officer of the Workhouse, Shore-ditch Union, London, E.
- POTTER, H. P., F.R.C.S., M.R.C.S.E.,** Resident Medical Superintendent to St. Mary Abbott's, Kensington.
- TOWLER, H. J., M.R.C.S.E.,** Medical Officer to the Barrowden District of the Uppingham Union.
- WALTER, W., M.D., L.K.Q.C.P.I., L.R.C.S.I.,** Honorary Surgeon to St. Mary's Hospital, Manchester.

## Births.

**ADAMSON.**—Jan. 9, at Hutton-le-Hole, Durham, the wife of James Adamson, M.D., of a daughter.

## Deaths.

- BARFOOT.**—Jan. 5, at Freshwater Villa, Surliton, Edward Wade Barfoot, M.R.C.S., aged 74.
- BUCK.**—Dec. 29, at the County Lunatic Asylum, Leicester, John Buck, M.R.C.S., for twenty-eight years Medical Superintendent of that Asylum, aged 64.
- DAVISON, R. S., M.R.C.S.E.,** Medical Officer of Health for the Castleward Rural Sanitary District, Northumberland.
- EVANS.**—Dec. 31, at Rome, of typhoid fever, George Harrison Evans, M.B., F.R.C.S., of Chad Road, Edgbaston, elder son of the late G. F. Evans, M.D., F.R.C.P., Birmingham, in his 35th year.
- ELPHICK.**—Jan. 5, at 16 Harwood Road, Lewisham, Mary, widow of the late Wm. Elphick, M.R.C.S., of Plaistow, Essex, aged 42.
- FLEMING.**—Dec. 30, at Donnybrook, co. Dublin, Christopher Fleming, M.D., ex-President of the College of Surgeons, Ireland, aged 80.
- KNOTT.**—Jan. 8, at his residence, Harwich, Wm. Knott, M.R.C.S. (half-pay), 6th Inniskilling Dragoons, aged 88.
- LEVER.**—Dec. 23, at Gowran, co. Kilkenny, John Lever, M.B., F.R.C.S., aged 48.

## DR. MARTIN'S RUBBER BANDAGES

(GENUINE),

By far superior to any of the numerous imitations, are now being sold at less cost than those of other manufacture.

**IMPORTANT NOTICE.**—Each Bandage bears Dr. H. A. Martin's signature, without which none is genuine.

No. 1a. 10½ ft. by 3 in., No. 23 wire gauge, price 4s. 0d.  
No. 8. 14 ft. by 3 in., No. 28 wire gauge, " 5s. 6d.  
No. 9a. 21 ft. by 3 in., No. 28 wire gauge, " 7s. 6d.

No. 1a. 10½ ft. by 3 in., No. 24 wire gauge, " 5s. 9d.  
No. 7. 14 ft. by 3 in., No. 24 wire gauge, " 7s. 0d.  
No. 9a. 21 ft. by 3 in., No. 24 wire gauge, " 10s. 6d.

Complete Price List also Dr. H. A. Martin's Pamphlet describing the Method of Treatment, post free on application to the Sole Agents, KROHNE & SESEMANN, Surgical Instrument Makers, 8 Drake Street Manchester Sq., London.

## DR. FELTON'S INHALER

(PATENT),

FOR THE INHALATION OF

CHLORIDE OF AMMONIUM

AND VARIOUS

MEDICATED VAPOURS,

For use in the treatment of

HAY FEVER, ASTHMA,

BRONCHIAL and CATARRHAL

AFFECTIONS, etc.

SOLE AGENTS for the UNITED KINGDOM,

SAVORY &amp; MOORE,

Descriptive Pamphlet on application.

The Inhaler occupies the space of an ordinary 3-oz. bottle.

Price 5s. 6d.

## MEDICAL AND OTHER OPINIONS ON THE SOLUBLE ESSENCE

- "Singularly free from resin."—*The Lancet*.
- "It is a pure, elegant preparation, and is free from resinous matter."—*Medical Times and Gazette*.
- "It should entirely supersede the official preparation of the British Pharmacopœia."—*Medical Press*.
- "It is a pharmaceutical desideratum."—*The Chemist and Druggist*.
- Dose.—Ten or 15 minims to Half-a-Teaspoonful in a Wineglass of Water.

*Medical and other Opinions on the Ginger Beer made from the Soluble Essence.*

- "An excellent effervescent drink."—*The Lancet*.
- "Clear and transparent, and very pleasing to the palate."—*Medical Times and Gazette*.
- "Extremely grateful and palatable, and certainly preferable to some wines we have tasted under the name of champagne."—*Medical Press*.
- "Has the purest Jamaica ginger aroma, distinguishable as soon as poured out. It is a beverage fit for any gentleman's table, and ought to attain great popularity."—*The Chemist and Druggist*.
- "Stands in the foremost rank of aerated waters."—*Mineral Water Trade Recorder*.

### ALCOHOL AS AN ANTISPASMODIC. (a)

By BENJAMIN WARD RICHARDSON, M.D., F.R.S.,  
President of the Medical Temperance Association.

(Concluded from page 24.)

THERE is another form of case, in which there is acute recurring spasm in the stomach or intestines, and in which, after taking food, or after long abstinence from food, or after much mental or bodily fatigue, the patient is seized with severe pain and faintness, which are not relieved until there is escape of flatus. These cases are sometimes, as we all know, accompanied by what is called gastrodynia, and the spasm, which is their marked symptom, varies from uneasiness and oppression to the most acute suffering.

In this state of disease there cannot be a doubt that alcohol gives relief. It reduces spasm, and permits the free escape of gaseous products, and so it relieves pain, and brings speedy quiet. There are no cases in which alcohol acts more promptly than these. There are, unfortunately, no cases in which it proves a worse friend. On one hand we must not, by any false enthusiasm, deny its efficacy. On the other hand we must not, by any bigoted sentiment for it, deny its danger. Carried a very little too far, it loses its effect, until a slowly fatal dose becomes almost a necessity of life. The patient, under the physician's own guidance, is, in fact, rescued from Scylla to be sacrificed on Charybdis. These are, *par excellence*, the cases that excite in the weak the desire for alcohol. The sufferers are of nervous or nervous lymphatic temperament, and they soon like and long for more than the direct relief from the too diffusible stimulant. From the local relief they court the universal degeneration.

I rarely see a week go by without having before me one or more of these examples of what may well be called nervous indigestion and spasm. I confess at once the extreme trouble and anxiety they give to a conscientiously anxious mind, which has to balance between the certain immediate good and the all but certain and distant evil.

I begin, always, the treatment of these cases without resort to alcohol. If I find that the sufferers have pyrosis, which is a very common accompanying symptom, I forbid specially two kinds of food, oatmeal porridge and tea. Tea I always counter-order, especially afternoon tea; and if the patient is a smoker I do my best to stop that habit. I then prescribe for the dyspeptic symptoms correctives for the secretions, and one or other of the digestive ferments pepsine, pancreatine, or diastase. For the spasm I prescribe bicarbonate of ammonia and potassa, with nitrite of amyl and infusion of cloves, using glycerine as the solvent for the nitrite. The prescription usually runs:—

Bicarbonate of ammonia, grā. v.;  
Bicarbonate of potassa, grā. x.;  
Glycerine, ℥j.;  
Amyl nitrite, m. ij.;  
Infusion of cloves, ℥j.

To be taken when the spasm is present, and to be repeated every hour until relief is obtained.

Only when this fails, or when this and other agents fail, do I resort to alcohol. Then I add to the above mixture from half a fluid ounce to six fluid drachms of '830 alcohol, for brief periods of time, withdrawing the alcohol as speedily as is possible.

Looking upon neuralgia as a form of vascular spasm in tracts of nerves, we have a very clear idea of the reason why antispasmodics are so useful in some forms of this disease, as immediate remedies. The alcohol in port wine has, for this reason, obtained its reputation for the relief of tic. But if, after the relief from relaxation has been obtained, there is one agent more than another which sustains the systemic irritation on which the pain rests, it is alcohol in any shape, and especially in that unknown sweet quantity called, ironically, port wine.

Admitting, therefore, the relaxing power of alcohol in the neuralgias, we have, in using it, always an ultimate

(a) Essay read at the First Meeting of the Session 1880-81 of the Medical Temperance Association.

danger to face, and happily we are not, I think, any longer obliged to face that danger. In croton chloral, and in croton chloral combined with quinine, we have an instant remedy, more effective than alcohol, and free of its reserved evil. For a year now I have successfully replaced alcohol by this new combination, for the use of which I am indebted to my good friend Dr. Elliot, of Hull. The formula is as follows:—

Croton chloral, gra. ij.;

Quinine, gra. ij.;

Glycerine, as much as suffices to make a pill.

The pill to be taken when the attack threatens, and to be repeated every two hours until relief is obtained.

The peculiarly painful spasm which attends the menstrual period in some women, and which becomes neuralgic in its character, is another affection strictly under my present subject. I do not deny for a moment that in these cases a full dose of alcohol—a very full dose—often repeated, relaxes, and so brings relief. But, perhaps, never was so much evil bought at the price of this temporary good as in these examples. That utterly untrustworthy compound sold as gin is the fluid with which these unhappy sufferers, often in early years, are dosed on these occasions. One of my lay friends who has a large number of women in his employ in a factory, writes to me on this topic, stating the demoralisation that the practice brings. He says, “In the young hands the time when the natural period is on is easily known by the odour of the gin in their breath.” “My wife,” he adds, “with motherly care, has been frequently amongst them to try to persuade them from the practice, for unfortunately the habit of taking the gin at these times soon infects the whole flock—sufferers and non-sufferers alike. But all her efforts are unavailing. The reply is that the gin generally relieves the pain, and, when the doctor is referred to, he is said to confirm the statement, and I have been told that you confirm it. But cannot something else be done?”

In better classes of society than factory girls this same practice prevails, and we have all of us often to sanction it or replace it. It struck me some time ago, as I have once before stated here, that possibly the juniper which is present in gin might be, in some degree, the useful agent. Juniper increases the secretion from the kidney like ethyl nitrite, and might be worth using, apart from the idea of gin. I have, therefore, given it in combination with croton chloral in proportion of three minims of the oil with two grains of the croton chloral made into a draught with glycerine and water.

This answers exceedingly well, and I press its use earnestly on your attention. The formula stands as follows:—

Croton chloral, gra. ij.;

Oil of juniper, m. iij.;

Glycerine, ℥j.;

Distilled water, ℥j. ss.

To make a draught. To be taken when in great pain, and repeated every five or six hours until relief is obtained.

In the spasmodic varieties of hysterias, with its neuralgias and other mimics of disease, we meet with many conditions in which the questions that have been already before us come up for consideration.

In these states of systemic derangement we have to confront conditions in which the immediate action of alcohol as an anti-spasmodic might be indicated. Here, however, according to my mind, a line should be sharply drawn. If there is any known agent which above all others sustains the hysterical condition, it is alcohol. For this reason I, for my part, leave it out of the list of remedies altogether, not because I doubt its effect to relieve, but because I am sure that its effect to sustain the evil far out-balances the temporary advantage. There is a stage of alcoholic intoxication, the second, which practically is a form of hysteria, and I know of no precise method of prescribing alcohol that shall not impinge upon that stage and intensify it.

I have, I trust, now given to alcohol all the credit as

an anti-spasmodic that belongs to it. I have given to it a wide range of action; I have not disguised its value; I have not concealed its dangers.

Let me now pass on to consider the mode of administration of alcohol for medicinal purposes.

In my lecture on the Alcohols, published so far back as 1869, in the *Medical Times and Gazette*, I wrote:—“As yet alcohol, the most commonly summoned of accredited remedies, has never been properly tested as a remedy for human diseases. I mean by this that it has never been tested as alcohol of a given chemical composition, of a given purity, and in given measures. Wines, beers, and spirits are anythings, compounds of alcohols, and compounds of alcohols with ethers and other foreign substances. It is time now, therefore, for the learned to be precise respecting alcohol, and for the learned to learn the positive use of one of their most potent instruments for good or for evil.” In the eleven years that have passed since that was published, I have steadily followed out the practice there suggested, and for five years past I have never prescribed alcohol in any other form than the .830 ethylic alcohol—the ordinary pure, but not quite absolute alcohol of commerce. I have known, therefore, in prescribing alcohol, for these five years, the precise thing prescribed, which is, I think, what few can say. I have by this means learned the value of dose, as well as of action. If I have wanted any other of the agents that belong to alcoholic beverages—the bitter of hop, diastase, and ether—I have added it in the same precise manner, and I most respectfully suggest that this is the only way in which alcohol can be scientifically applied in the treatment of disease. The advantage is all on the side of accuracy.

There is another and more cogent reason for this rule. By following it alcohol is kept in the hands of the prescriber and the chemist. When it has served its purpose it can, like mercury or arsenic, or other dangerous remedy, be withdrawn. Ordered as a common drink, instead of being prescribed, the patients become their own doctors and their own destroyers. It is hard enough, as we have seen, so to prescribe alcohol as to prevent evil from it; to order it without care is to endanger its current utility, and to make the perpetuation of its evils the most imminent of dangers.

An inquiry which springs out of these studies is the possibility of advancing further in the line of discovery towards substitutes for alcohol as an antispasmodic. I have shown that amyl nitrite may well come in for such substitution; and to this may be added either ammonia, methylic alcohol, or methylal. The two last-named remedies, when they are perfectly pure, are admirable substitutes. They are rather quicker in action, and the latter, methylal, is more pronounced in its effects as an antispasmodic.

On the mode of administering alcohol by prescription a word may be useful. I prescribe .830 alcohol, adding to it usually a little glycerine; one drachm of glycerine to the half-ounce fluid measure of alcohol and water. For those adults who are not accustomed to alcohol, half a fluid ounce of it in two ounces of water is a good standard dose. That dose will produce a distinct physiological effect. It will quicken the pulse to two thousand beats, and it will cause a preliminary rise of a fourth of a degree of surface temperature. This dose may be repeated every hour for four hours without harm, but not beyond that time with impunity.

For ordinary drinkers of alcohol the dose is small. They will take an ounce, or an ounce and a-half at once and not be seriously influenced, and to them, in emergency, the larger of these doses may not be too considerable. Its repetition must, of course, be considered with great care.

To us, who are engaged in the active work of the temperance reformation, these truths on the medicinal use of alcohol are of vital moment. It is as vain as it is untrue for us to declare to our patients that alcohol cannot relieve them under certain conditions. If we tell

them so, and suggest other plans, they simply resort to the thing itself, in its worst combinations, and instead of using it medicinally, they follow up the use of it, without asking our leave and not knowing when to stop. We, therefore, lose the benefit of applying it as a remedy, and of stopping the use of it when it has performed its purpose. Thus we lose influence in a double sense. To those, again, who are not engaged in our contest; to those who with cruel apathy treat the temperance reformation as a sublime joke, and its leaders with scoffing contempt, these studies are not less vital. Soon it will be learned, even by them, that the temperance movement has a root which cannot be drawn, and a development which cannot be suppressed. Then will come a time when the lay voice will be heard, standing out against the empirical use of alcohol altogether, and questions will be put and arguments used that will be as fatal to the interests of our professional body as all kinds of class bigotry, pride and fanaticism, ever have been, when they have ventured to cross swords with advancements the power of which has been foreseen by all except those who were most interested in their recognition.

### THE ACTION OF ANÆSTHETICS. (a)

By JOHN GRAY M'KENDRICK, M.D., F.R.C.P.,  
F.R.S.E.,

Professor of Medicine in the University of Glasgow.

Dr. M'KENDRICK said that in 1846 the use of ether was first known in America as an anæsthetic. It was practised first by a dentist, Dr. Morton, who said that the substance was first suggested to him by a physician, Dr. Jackson, and first used in dentistry. It very quickly was used in surgical operations, and spread very rapidly over America and the Continent. In the following year Sir James Simpson was led to the administration of chloroform as an anæsthetic, and it very quickly took the place which it still possessed in this country. The number of deaths occurring during the administration of chloroform were not numerous certainly, taking into account the large number of cases in which chloroform was administered for surgical purposes, but still they were often unlooked for, and gave rise to a certain feeling of distrust in the minds of some medical men, at all events, as to the use of this principal anæsthetic. In 1875, when the British Medical Association met in Edinburgh, a large committee was formed of leading surgeons in the principal towns of this country, but it was too bulky for practical work, and two years passed without any action being taken. In 1877, at the meeting of the British Medical Association in Manchester, a much smaller committee was formed, and this committee consisted of John G. M'Kendrick, M.D., Professor of Physiology in the University of Glasgow; Joseph Coats, M.D., Pathologist and Lecturer on Pathology, Western Infirmary, Glasgow; and Wm. Ramsay, Ph.D., assistant to the Professor of Chemistry in University of Glasgow. Dr. Ramsay retired from the committee on his appointment to the chair of chemistry in the University College, Bristol, when David Newman, M.B., Pathological Chemist, Western Infirmary, Glasgow, became a member of the committee. The object of the committee was to investigate generally the physiological action of anæsthetics, and, if possible, ascertain the sources of danger from their use, and perhaps also to suggest an anæsthetic which would be freer from danger than those in use. It was, of course, not the object of the committee to get up anything in the nature of a scare with regard to the use of anæsthetics. They had been so far too good servants in the hands of the surgeons of this country to be hastily thrown aside; but their object was to find out an anæsthetic which would be safer than those now in use; to find, if possible, the source of danger, and to indicate how these dangers might be avoided or overcome. The action of an anæsthetic

was very quickly seen by its interferences with the higher nervous centres. A person might become slightly excited, but after a period of excitement there came a period of confusion, and if anæsthesia was pushed still further there would come a period of complete insensibility, while at the same time the lower nervous centres connected with the movement of the heart, and with the movement of respiration, were interfered with. It was well known to surgeons that if anæsthetics were pushed too far the persons might suddenly die, either from failure of the heart's action or from failure of respiration. Dr. M'Kendrick then narrated experiments that had been made on cold and warm blooded animals, and from these it was ascertained without doubt that chloroform had an injurious influence on the heart, and that ether had not the same injurious influence. They then proceeded to ascertain whether they could find an anæsthetic which would not have the disadvantages of ether or chloroform. Ether as an anæsthetic was somewhat troublesome to use. It required a much larger dose of ether than of chloroform, and a longer time was taken to put an individual under ether than under chloroform, and after under its influence a person was more liable to come from under its influence quietly. Consequently it was important to look about and, if possible, find out some anæsthetic which would come midway between them. A number of substances were tried, and the best they could get were Isobutyl chloride and ethidene dichloride. The experiments with the latter were exceeding good. Under it frogs continued paralysed from 20 to 26 minutes, and there was no interference either with the action of the heart or with the respiration. With regard to ethidene dichloride, it was found, on looking up the literature of the subject that Dr. Snow, of London, in 1858 had experimented with it, but said that it was not likely to come into use on account of the difficulty of obtaining it in a state of purity. Since the committee brought the matter before the profession on January 18, 1879, it was being used in this country to a considerable extent. In Glasgow it had been given to a considerable number of human beings, and in London up to the 29th May last year. Mr. Clover had reported on 1,877 cases, on the whole favourably. Dr. M'Kendrick then explained the nature of several experiments which were made in order to compare the action of the ethidene with other anæsthetics, and, if possible, ascertain its influence on the living organisms, and then find out the influence of it upon what was called blood pressure. He explained that a falling of blood-pressure indicated generally that the heart was becoming rapidly enfeebled. This was exemplified in a series of drawings, showing the results obtained from the experiments made on the animals. These showed that in the use of chloroform there was a tendency to a sudden fall of blood-pressure, with ethidene the fall was gradual, but with ether the pressure was kept up steadily for a lengthened period. Dr. M'Kendrick then referred to several experiments that had been made by Dr. Newman, with the permission of the surgeon of the Glasgow Western Infirmary, and the results of these had been elaborately tabulated. The practical results were that when chloroform was administered the appearance of the countenance of the patient might be that of pallor, and if pushed further, deep breathing would be manifested; but when ethidene was administered the countenance of the patient was remarkably natural. One difficulty was that ethidene at first seemed to be more liable to produce sickness, and, of course, it was a matter of great importance to have no sickness after certain operations. The general effect, however, seemed to be that ethidene did not produce sickness to a greater extent, at all events, than chloroform, and that the sickness did not last for so long a time. Dr. M'Kendrick summed up the general results of the inquiry as follows:—  
With regard to the physiological effect:—1. The effect of anæsthesia with chloroform is to increase the amount of carbonic acid exhaled in a given time. 2. Both chloroform and ethidene, administered to animals, have a decided effect in reducing the blood-pressure, while ether has no

(a) Read at the meeting of the Glasgow Philosophical Society, January 6th, 1881.

appreciable effect of this kind. 3. Chloroform reduces the pressure much more rapidly, and to a greater extent, than ethidene. 4. Chloroform has sometimes an unexpected and apparently capricious effect, the pressure being reduced with great rapidity, almost to *nil*, while the pulsations are greatly retarded, or even stopped. The occurrence of these sudden and unlooked-for effects on the heart's action seems to be a source of serious danger to life—all the more that in two instances they occurred more than a minute after chloroform had ceased to be administered, and after the recovery of the blood-pressure. 5. Ethidene reduces the blood-pressure by regular gradations, and not, so far as observed, by these sudden and unexpected depressions. 6. Chloroform may cause death in dogs, either by primarily paralyzing the heart or the respiration. The variations in this respect seem to depend, to some extent, on individual peculiarities of the animals. In some, the cardiac centres are more readily affected; in others, the respiratory. But peculiarities in the condition of the same animal very probably have some effect in determining the vulnerability of these two centres respectively, and they may both fail simultaneously. 7. In most cases, respiration stops before the heart's action; but there was instances in which respiration continued while the heart had stopped, and only failed a considerable number of seconds after the heart had resumed. With regard to the practical results, it seems to be this—that, as regards comparative danger, the three anaesthetics may be arranged in the following order: chloroform, ethidene, ether; and the ease with which the vital functions can be restored may be conversely stated thus: the circulation is more easily re-established when its cessation is due to ether than to ethidene, and when the result of ethidene than when chloroform has been used. The advantages which chloroform possesses over ether—in being more agreeable to the patient, and more rapid in its action; in the complete insensibility produced by it, and the absence of excitement or movements during the operation—are more than counterbalanced by its additional dangers. The chief dangers are—(1) Sudden stoppage of the heart; (2) reduction of the blood-pressure; (3) alteration of the pulse respiration ratio; and (4) sudden cessation of the respiration. The danger with ether approaches from the pulmonary rather than from the cardiac side, so that by establishing artificial respiration we have a means of warding off death. Its disadvantages are to a great extent obviated by the use of ethidene, whilst the dangers of chloroform are also reduced to a minimum. In concluding, Dr. M'Kendrick said his own impression as to the results of this investigation was that those surgeons who required to use an anaesthetic would select one for particular cases. There were certain cases where chloroform might be best, and other cases where it would be better to give ethidene, which was really physiologically and clinically midway between the two—chloroform and ether. Then it might be said, why not use ethidene more frequently than it was at present done? The reason was a practical one. It was far too expensive at present, and ever since the committee began their work—although much more of it has been used—for some reason it was not manufactured now. It is now very costly; but if any one could manufacture ethidene at a much more reasonable price, he had not the slightest doubt it would be used pretty frequently as an anaesthetic.

## DISEASES OF THE HEART IN CHILDREN.

By W. H. DAY, M.D., M.R.C.P. Lond.;  
Physician to the Samaritan Hospital for Women and Children.  
(Continued from page 27.)

### VALVULAR DISEASES OF THE HEART.

The general symptoms of valvular disease of the heart may be thus briefly stated. The blood is either impeded in its passage through the heart, or it regurgitates from defect in the closure of the valves, and this leads to hyper-

trophy with congestion of the lungs and other organs, followed by dropsy. The symptoms vary a good deal, and in children, even when the valvular condition and hypertrophy appear to be about equal, the constitution suffers differently. This arises from the conservative process of hypertrophy, which, for a long time, keeps in check the symptoms; but, by and by, the heart labouring to empty its overplus, fails, and congestion of the venous system follows. Then ensue hurried respiration, dyspnoea, pain in the region of the heart or palpitation, anxiety of expression, pallor or suffusion of the face, inability to walk up stairs, and the impossibility of resting in the recumbent position. The symptoms are increased by indigestion or mental emotion. The valves on the *left* side of the heart, are far more prone to disease than those on the *right*. When the latter are affected, it has been attributed to foetal endocarditis.

The constitutional symptoms in these cases are liable to considerable variation. Some children who have all the physical signs of a severely damaged valve, as the consequence of rheumatic endocarditis, experience no breathlessness, and scarcely any other discomfort. They may go on for months or years with very little complaint. I have more than once known the heart entirely overlooked in these cases, and the symptoms of impaired health ascribed to weakness and general debility. But later on, the symptoms of obstruction to the circulation begin to be manifest, and there is cough, congestion of the lungs, and hurried breathing. In prolonged cases, the liver and digestive organs become deranged, the features are swelled, and oedema of the extremities supervenes.

*Diseases of the aortic valves* is so rare in childhood that it might be passed over unnoticed. But, since it does now and then occur in children, it is well to call attention to this lesion. When the aortic orifice is narrowed or constricted (*aortic obstruction—**aortic stenosis*), the blood is impeded in its passage from the left ventricle. Over the mid-sternum, but more especially over the second right costal cartilage, and in the course of the aorta and carotids a soft systolic murmur, corresponding in time with the pulse, is heard, diminishing in intensity towards the apex. A systolic thrill is often felt over the cardiac region, at the right base, with heaving impulse. There is usually great hypertrophy of the left ventricle. If the heart's action is weak, and the narrowing of the orifice smooth, the murmur may not be easily detected. When the narrowing is great, the pulse is small and feeble, but this will in some degree depend upon the amount of hypertrophy present, which modifies its character. The constitutional symptoms are pallor of the countenance, and often headache from cerebral anæmia, owing to the unfilled state of the arteries. Unless the mitral valve becomes involved, so as to allow of regurgitation taking place, the pulmonary circulation is not interfered with.

*Causes.*—These are most probably due to chronic valvulitis, and to endocarditis after rheumatic fever. When rheumatic endocarditis happens, the inflammation begins in the mitral valve, and then, after involving the ventricular endocardium, seizes upon the aortic valves. These remarks on aortic obstruction in childhood are rather theoretical than the result of my own clinical observation. The form assumed by aortic valvulitis in childhood is certainly that of regurgitation, the distortion and mutilation of the valves commences in their free edges, and is usually accompanied by dilatation of the aortic conus, and the actual enlargement of the aortic ostium.

When the aortic valves cannot effectually close the orifice on the aortic recoil, the blood stream returns into the ventricle, and *aortic regurgitation* is produced. The physical signs are a diastolic murmur heard at the mid-sternum obliterating the second sound, and frequently distinctly audible at the apex. It may be soft or rough, weak or loud, musical or prolonged. The pulse is sudden and jerking; it is known as "Corrigan's pulse," collapsing "like balls of blood shot under the finger," but there

may be considerable regurgitation without this being marked, or any visible pulsation in the superficial vessels.

The tendency of the disease is to produce extreme hypertrophy of the left ventricle, but very rarely any dropsy. The ventricle being always too full of blood undergoes comparative hypertrophy, and containing blood in diastole, dilatation is added to hypertrophy.

Dr. de Havilland Hall afforded me an opportunity of seeing a patient of his, a boy ten years of age, who was the subject of aortic regurgitation. Six weeks before he came under observation, he had complained of pains in his knees and feet, and had been confined to bed one week. When seen he was suffering from weakness and giddiness, and shortness of breath on exertion. On examination, he was found to have a soft aortic diastolic murmur, heard loudest over the third right interspace close to the sternum, and conducted along the sternum to the apex. The impulse was greatly diffused, but most marked in the fifth interspace in the nipple line. There was visible pulsation in the brachial arteries.

*Causes.*—This affection may possibly be congenital. It may also follow chronic changes, violent strains, and endocarditis after rheumatism in obstructive disease.

*Disease of the right auriculo-ventricular orifice (tricuspid regurgitation)* is rare, and murmurs are uncommon in this situation, except in long standing cases of mitral disease, in which the right side of the heart has become weakened, and there is obstruction to the pulmonary circulation. "Mitral stenosis is the most frequent cause of serious tricuspid regurgitation, and the earlier in life the stenosis occurs, the more rapidly, as a rule, the tricuspid regurgitation follows, and the more serious the prognosis. (a) The physical signs are increased præcordial dulness to the right of the sternum, at the level of the fourth rib, and epigastric pulsation, the ventricle being seen and felt between the ensiform cartilage and receding ribs in the left hypochondrium. Owing to the accumulation of blood in the right ventricle from congestion of the lungs, it becomes enlarged and dilated. As it encroaches on the position of the left ventricle, and lies in front of it, the apex is pushed away from the chest wall, and the impulse is extremely weak or cannot be felt at all. A murmur usually accompanies the systole, and is most audible over the lower part of the sternum, or ensiform cartilage. I say usually, because the murmur is altogether absent in some cases, and in others it cannot be detected, though the other signs of tricuspid incompetency are all present. Accentuation of the pulmonary second sound should be looked for, and weakness of the aortic sound. The increased outline can often be distinguished readily enough in children, whose chest walls are thin, and the left lobe of the liver may receive an impulse, while at the same time the liver is not unfrequently enlarged. This condition is often attended with over fulness of the cervical veins, because the right auricle is over-distended, and in fact the right side of the heart altogether undergoes passive dilatation. The tricuspid being insufficient, each contraction of the right ventricle drives backwards the blood into the right auricle, and the veins in communication with it. The wavy pulsation in the external jugular veins is an indication of considerable tricuspid regurgitation, but if the orifice is only slightly contracted, then the valve may act efficiently, and the pulsation in the vein be absent. Congestion of the intestinal veins, scanty urine, and even hæmorrhoids are sometimes present. In a boy, aged eleven years, under my care in 1877, or mitral and tricuspid disease, œdema and anasarca of the lower extremities came on a month before death.

When the cardiac enlargement exists to the same extent in two separate cases, we may have in one case regular bowels and normal extremities, with the power to lie down and assume any position; whilst in another case there are severe and continuous congestive headache, enlarged veins in the neck and pulmonary engorgement.

This depends upon the amount of injury the valve has sustained. If the tricuspid orifice is only partially contracted, and there is no defect in the valves, the venous circulation is partially congested; for it should be held in mind that a murmur in this situation, like a mitral regurgitant murmur, may be simply the expression of great debility.

A systolic murmur heard most distinctly over the pulmonary orifice is generally due to anæmia, or to pressure by consolidated lung. When organic it is almost always congenital.

*Disease of the left auriculo-ventricular (mitral) valve*, causing regurgitation from the ventricle into the auricle is the most common form of cardiac disease to be met with. It is evidenced by a murmur, diastolic in time, and unlike that of mitral stenosis is not caused by the contraction of the auricle. It is very much more frequent in girls than in boys. In these cases there is enlargement of the left ventricle, and the apex beat is below and external to the nipple; it often occupies a larger space than in health, except when it strikes directly behind a rib, and then it is not detected so readily. The impulse is considerable and heaving, and if the hand be placed over the præcordial region, there is an appreciable thrill. Over the apex is a bruit accompanying the systole, partially obscuring the first sound, and diminishing, or even disappearing at the base, if only slight; but if loud or intense, it may almost obliterate the second sound at the apex, and be detected over the whole præcordial region. The murmur is synchronous with the pulse, and owing to the blood being carried back into the left auricle, can be heard in the left axilla, at the angle of the scapula on the same side, and at the spinal column. The pulmonary second sound is generally intensified. This murmur (*bruit de soufflet*) is soft and bellows like in recent cases, where possibly the deposit on the valve has become highly organised, but in more advanced cases it is rough and grating, and resembles the sawing of wood. The purring tremor—*frémissement cataire*) occasionally found in disease of the mitral orifice is essentially connected with obstructive, and rarely, if ever, with mitral regurgitant disease. Cough, congestion of the lung, quick breathing, and a small contracted pulse, are common in these cases.

A loud apex murmur in mitral disease is compatible with fair strength and growth, and may be present without impairing the functions of the heart. In such cases there is probably a mere roughening of the surface of the valves, or even a vegetation, which does not permit any of the blood in the ventricle to flow back through the mitral orifice, yet a systolic apex bruit may be present, and regurgitation take place with a competent mitral valve. "In fact, the mitral valve may be perfectly free from disease, and the auriculo-ventricular opening perfectly natural and undilated, and yet regurgitation may, and often does, take place." (a) In anæmia and chlorosis a venous murmur may sometimes be heard over the mitral area, accompanied with accentuation of the pulmonary second sound, as in true mitral constriction and regurgitation, but unassociated with any valvular lesion. There are other cases in which the physical signs are the same, but graver mischief has been done, and the right side of the heart and lungs suffer in time. Children so affected, are small, dwarfed and stunted, and liable to die of dropsy at puberty. They rarely get over the pubertal changes.

(To be continued.)

At the last meeting of the Sanitary Institute of Great Britain, Dr. B. W. Richardson in the Chair, eight Fellows were elected, among whom were the Bishop of Exeter, Sir Stafford Northcote, and General Bartlett. Two members were also elected, and applications read for the election of others at next meeting.

## ON SANITATION. (a)

By C. A. CAMERON, M.D.,

President of the Society of Medical Officers of Health, Dublin.

In 1879 the provisions of the Public Health Acts of 1878 and 1879, came into force in reference to the returns of burials to be made by the cemeteries authorities to the registrars of deaths. In former years it was estimated that about 11 per cent. of the deaths that occurred in Dublin were not registered, but since the burials returns have been received this serious omission in death registration has been remedied. The corrections afforded by means of the returns from the cemeteries authorities would account for 10 or 11 per cent. of the increase in the registered deaths in 1879 and 1880 as compared with previous years. Thus the average of 27.1 deaths per 1,000 during the ten years ended in 1878 would have been 30 per 1,000 persons living if the registration of deaths had been corrected by returns of interments from the cemeteries authorities. It thus appears that in the Dublin registration area, the death-rate in 1879 was 4.6 per 1,000, or nearly 1.5 per cent. in excess of the average (corrected) death-rate of the previous ten years. Now the questions arise—1. What are the causes of the somewhat high rate of mortality which prevailed in Dublin before 1878? 2. How are we to account for the great increase in our bills of mortality which occurred in 1879 and 1880? It appears to me that it is much easier to answer the former of these questions than the latter. The bad condition of the tenement dwellings, the existence of ill-kept slaughter-houses and dairy-yards in the most densely-crowded parts of the city, the prevalence of poverty, intemperance, and uncleanness are prime factors in the production of our high death-rate. It is, however, difficult to account for the increase in the unhealthy condition of Dublin which has occurred since 1877, but more especially since 1878. During the last two years the condition of the tenement dwellings has certainly been improved, the sewerage system has been extended, and the streets have been kept cleaner.

The high death-rate in 1879 and 1880 has not been caused by any disproportionate increase in the number of deaths from zymotic diseases. Small-pox carried off 520 persons in 1879, but in 1878 this disease killed 560 persons. Scarletina was more destructive in 1879 than in 1878 and 1880, and in the latter year there was a very high and unusual mortality occasioned by diarrhoea. On scrutinising the death statistics of 1879 and 1880, it will be seen that the deaths from zymotic diseases and from all other of the great classes of diseases had increased in equal ratios, as compared with the average mortality from these maladies during the previous ten years.

## THE CAUSES OF OUR HIGH DEATH-RATE.

It is probable that the bad harvests of 1877, 1878, and 1879, have had some influence upon the condition of the public health, even in the case of the towns. In 1879, and the early part of 1880, great destitution prevailed in Dublin, and in many of the provincial towns. Visiting as I do daily the tenement dwellings, I have ample opportunities of observing the social condition of the poorer classes. During the last two years I have witnessed great destitution among the labouring and even the artisan classes. Their rooms were miserably furnished, their clothing and bedding scanty and ragged, and their food defective in quantity and quality.

One of the most saddening of the sights witnessed by those who inquire into the condition of the very poor, is afforded by the children who are not old enough to work. There are thousands of them miserably fed, clad in rags, and shoeless. Little boys from six to ten years old are commonly to be met with clothed in the remnants of their fathers' garments, their breasts and the lower parts of their legs exposed to the biting winds and frosts of winter. When these wretchedly-clothed and semi-nourished children catch measles, scarlatina, or other zymotic disease, is it to be wondered at that their enfeebled little bodies are incapable of resisting the onslaught of these diseases? Having given this matter some attention I say advisedly that the children of the labouring classes, and, to some extent, those of the artisans are worse clothed and shod than are the children of the same class in English towns. A short time ago I visited

(a) Read before the Society of Medical Officers of Health, Dublin.

a primary school near Watford, Hertfordshire, where there were about 200 girls, nearly all of whom were the children of labourers. Every child was warmly clad and provided with good boots. They were all neat and clean. I could not help contrasting in my mind's eye the tidy condition of these children with the squalid, ragged, unshodden, and filthy condition of so many of the children attending the primary schools of this city.

## THE TENEMENTAL DWELLINGS OF DUBLIN.

In the Report of the Royal Commissioners who inquired in 1879 into the sewerage arrangements of Dublin, it is stated that the tenemental dwellings are, according to the medical evidence tendered, "the prime source and cause of the excessively high death-rate" of Dublin. I do not fully endorse this opinion, for I believe that the bad condition of the tenemental dwellings is in a large proportion of cases an effect and not a cause. The poverty and intemperance of a large number of persons re-act upon their dwellings. Such persons placed in new and clean houses would soon render them dilapidated and filthy. Still, it is not to be denied that the wretched state of a large proportion of the homes of the poor is a matter beyond their control, and for which they are not to be held responsible. Nor can it be denied that the state of a very large percentage of the tenemental dwellings is inimical to health and morality. The defects of the tenemental dwellings appear to me to be mainly as follows:—

1. Many of them are built upon the yards or gardens of houses of an earlier erection, and are, therefore, deficient in air, light, and proper sites for water closets, privies, and ash-pits.

2. The greater number of families amongst the working classes inhabit each but one room, which is consequently generally occupied night and day, so that its atmosphere is always impure, and the apartment cannot be thoroughly cleansed.

3. As several families have the use of a common privy or water-closet, no one is immediately interested in keeping it clean; nor are the common hall, stairs, and lobbies of the tenement houses properly attended to for the same reason. In a large number of cases a person, generally an old woman, has a room rent free as payment for keeping the house and out-offices clean, but it is seldom that the work is properly performed. A few owners of tenemental dwellings employ men to keep them clean; in such instances the work is much better done.

4. The want of proper sanitary accommodation for females is all but general in the tenemental dwellings; such accommodation is only to be met with in the houses erected by the Artisans' Dwellings Company. I have no doubt that the lack of sanitary accommodation for a female population of the tenemental dwellings, which cannot be less than 25,000, must operate injuriously upon their health, and it certainly gives rise to uncleanly and unhealthy practices.

5. The circumstance that, as a rule, every room in a tenement house is occupied by a family, favours greatly the spread of contagious diseases. If a case of measles or small-pox occurs in one room of such a house, there is a great probability that the contagium of the disease will soon find its way into other rooms.

The evils which arise out of the present state of the majority of the homes of the poor require the most energetic and widespread measures for their eradication, or at least decided amelioration. Some of these measures I shall briefly describe. In the first place, I think in certain cases it would be desirable to insist that each person should be supplied with more than 300 cubic feet of space for sleeping which hitherto we have regarded as a minimal space for such purpose. Where the room is occupied only as a sleeping apartment, that space might be considered as sufficient; but where people live, cook, wash, clean, work, and sleep in one apartment, I think that the minimal space should be increased to 400 cubic feet.

I am of opinion that there is great danger to be apprehended wherever a large number of families occupy a large house having but one hall and staircase. I have met with several cases of such houses in which severe outbreaks of zymotic disease occurred. In some of these cases I insisted, and with success, on a reduction in the number of families occupying the house—in one instance to the extent of 50 per cent.

The bad odour which prevails in so many of the tenement

houses is often due to the state of their privies and ash-pits. These offices are generally in direct connection, and the contents of the latter are, as a rule, contaminated with those of the former, the whole being frequently converted into a semi-liquid state by rain. During the last two years it has been my constant aim to compel the owners or leaseholders of tenement houses to replace these filthy privies by water-closets of simple construction, and so far the result has been a tolerably successful one. About 40 water-closets per month are being put up, and, on the whole, they are kept in fairly good order, and undoubtedly they are a great improvement on the privies. One of our colleagues, Dr. Speedy, has been indefatigable in getting water-closets introduced into the houses of his district.

In reference to the subject of water-closets, I may say that I have great objection to putting them anywhere within the walls of the house. In a very few cases I have consented to have them placed inside houses, but only when the latter were large dwellings and of a superior kind. In every case the closet was placed in the top storey, and as far away from the dwelling-rooms as possible.

The sanitary authorities have great powers conferred upon them by recent sanitary statutes; and so far as the closing of houses unfit for human habitation is concerned, there is not much difficulty in effecting that object in Dublin, thanks, too, to the views which our police magistrates take. I must confess, however, that I often feel compunction in applying for the closing of houses—unless they are in an exceptionally bad state—belonging to poor persons, and who are unable to put their houses into a proper condition. There are many leaseholders who make a little profit out of subletting the houses. When houses of this class are compulsorily closed, it seems a hardship that the lessee should be compelled to pay his landlord rent for houses which had become unproductive. Legislation is required to remedy this grievance; and also to distribute the cost of putting houses into a proper state of repair, and of providing them with improved sanitary accommodation, on all the persons having a beneficiary interest in the premises.

#### IMPROVED TENEMENTS.

The Industrial Dwellings Company have done good work by erecting excellent and comparatively cheap dwellings for more than 2,000 persons, and they are about to erect additional houses on the large area in the Liberties lately cleared by the Corporation. This useful and energetic company are conferring great sanitary benefits upon this city, and I sincerely trust that ere long every hundred pounds of their capital may become a thousand.

#### CLOSING OF DWELLINGS UNFIT FOR HUMAN HABITATION.

From the 1st August, 1879, till the 31st December, 1880—a period of 16 months—604 houses and 197 cellar dwellings were closed in the city of Dublin, being unfit for human habitation. The greater number having been repaired and rendered tenable, have been re-opened; but a very substantial number have been allowed to go into utter ruin, whilst a few have been either pulled down or remain in much the same condition as when they were detenanted. It is most desirable that power should be given to the sanitary authority to take possession of any house allowed to go into a ruinous condition or to become derelict, and to sell it and have the site cleared and let for building purposes. This work might be done in trust for the owner, should one man be able to prove his claim and pay the costs of the procedure. There are large numbers of houses in Dublin which have been compulsorily closed, and have now become receptacles of filth and eyecores.

#### OUT-DOOR RELIEF.

There are drawbacks in the system of giving out-door relief, the seriousness of which has been, I think, overrated. In England the majority of persons receiving assistance under the provisions of the Poor-law get it in their homes. If a little assistance were given to certain classes of persons I am of opinion that the amount of illness and mortality would be lessened. Widows with young children, earning a little, but not sufficient to sustain life adequately, should be assisted. So also should women deserted by their husbands. In winter much benefit to health would result if the children of the very poor were supplied with some clothing as a species of out-door relief. In the case of persons recently discharged from hospital, but still too weak to work, out-door relief should certainly be given. It has been clearly proved by Stallard, Mitchell, and other eminent authorities, that the burden of supporting

the helpless poor should at least be equally borne by all the tax-payers of the district in which the poor work, and not upon the tax-payers of the district in which they reside. There is now a common fund for the poor contributed equally in proportion to the valuation of their properties or holdings by all the inhabitants of the London Metropolitan area. It is time that this equitable principle should be adopted in the Dublin Metropolitan district.

#### NOTIFICATION OF INFECTIOUS DISEASES.

This important subject was recently discussed before our Society, and a resolution adopted approving of its principle, and recommending that the notification to the sanitary authority should be made by both the physician and the person having charge of the patient. Mr. E. D. Gray, M.P., has introduced a bill into Parliament to render notification by the medical attendant compulsory. I trust this important bill will become law during the present session.

#### CONVALESCENT HOSPITALS.

It is much to be regretted that the efforts recently made to establish a convalescent hospital for infectious cases have failed. I am strongly of opinion that the management of convalescent hospitals of this kind should be entrusted to the authorities of the fever hospitals. I cannot help thinking that if the money subscribed two years ago towards founding an hospital for convalescents were given to, say, the governors of the Cork Street Fever Hospital, and that they were enabled by its means, and by other assistance, to establish a convalescent hospital upon even a very moderate scale, I have no doubt that the corporation would contribute as liberally as would be necessary towards the maintenance of the hospital. The public health authority are unable to manage an hospital, but no restriction is placed upon the pecuniary aid which the corporation are empowered to give towards its support.

#### CRÈCHES.

Very little has been done in Ireland in the way of establishing day crèches; no doubt this institution is much more urgently required in the manufacturing towns, but there is great room for it in Dublin. I constantly see very small children left at home by their mothers whilst the latter are out at work; and it is pitiable to see a child of the most tender years—of an age which, amongst a higher class, would be the object of a nurse's or elder sister's care—taking charge of a younger child. Amongst the poor, infants are the nurses of infants.

In conclusion, I have to congratulate our Society on our successful working during the past year. Many interesting subjects were brought under notice and ably discussed. No class of the community takes greater interest in the prevention of disease than the members of our profession; and in the vast domain of preventive medicine none have worked so hard or so successfully as the medical officers of health. I trust that ere long their valuable services will be recognised by a substantial increase of their salaries, which at present are utterly disproportionate to the status and labours of a most important class of public officers.

## Clinical Records.

### NOTES OF A CASE OF HYDROPHOBIA.

By WM. BERRY, M.R.C.S. Eng., & L.R.C.P. & S. Ed.,  
Surgeon to the Royal Albert Edward Infirmary, Wigan.

#### WITH REMARKS

By T. M. DOLAN, F.R.C.S. Ed., Halifax.

(*Medical Press and Circular* Special Commissioner for Reports on Rabies and Hydrophobia.)

J. D., æt. 40, mother of nine children, was bitten on the 19th of August, 1880, by a large dog (sheep and retriever). The wound was a jagged one, of a triangular shape, about one inch broad at its base, situate one and a-half inches above the left external malleolus. Her shoe and stocking were at once removed, and the wound, which bled freely, bathed well with warm water, bleeding thereby being encouraged. I saw her about one hour after the occurrence, and found her suffering from shock and excitement.

She was daily expecting her confinement, and being also of

a nervo-sanguineous temperament, the shock appeared greater than one would have expected from a similar wound derived from an injury other than a dog bite. She complained of great pain in the wound. I had it again bathed, and afterwards applied the vaunted specific, as a neutraliser of hydrophobic virus, namely, carbonate of soda in powder, completely covering the raw surface of the wound, applied then dry lint, and a bandage. Three days afterwards I delivered her of a fine healthy child after a natural labour.

The wound healed completely in the course of four or five weeks, but at times she complained of pains affecting the seat of wound, although the cicatrix appeared healthy, the pain extending up to her knee. She described the pain as being of a hot, burning character; with the exception of an attack of dyspepsia, and now and again supra-orbital neuralgia, she remained tolerably well till the 29th of December, being a little over four months after the bite, when, on washing, she complained of being very ill, and went to bed. The next day in the afternoon of the 30th December, she experienced difficulty in breathing after swallowing fluids, and attributed this to "wind on the stomach." I saw her on the 31st of December, about 7.30 a.m., and found her with a peculiar anxious expression, complaining of a sense of choking in her throat. Skin cold and clammy; tongue clean, pulse 84, regular, urine scanty, and of a deep colour; micturition frequent. She complained of a smarting pain in her leg, and severe pain in her genitals. On giving her a drink she tossed it down her throat in a peculiar manner, and after swallowing, a severe spasm of the larynx followed. Saliva was scanty. Solids could be swallowed without bringing on one of these attacks. I diagnosed the case to be one of hydrophobia, and prescribed for her the following mixture:—

R Chloral hydratis;  
Potassii bromidi aa ʒss.;  
Aque ad. fl., ʒviiij. solve;  
Sig. ʒj. Secundis horis

I then telegraphed to Dr. Dolan, of Halifax, and he kindly came over at once to see the case. We visited her with my friend, Dr. Tatham, at about 12.30 noon. She now appeared somewhat relieved, dosing a little from the effects of the chloral, but still the spasmodic attacks could be readily induced, even at times by the appearance of liquids. Pulse 90, thready and feeble. Temperature, 98°. Both Drs. Dolan and Tatham agreed with me that it was a true case of hydrophobia. On Dr. Dolan's recommendation I agreed to give her one dram doses of bromide of potassium every four hours, and fifteen grains of quinine every four hours. A vapour bath and beef tea and brandy *per rectum*.

At 5.30 p.m. I saw her again; found her in the same state, but weaker, although the spasms did not occur so frequently. I superintended the administration of the vapour bath, saw her in bed afterwards, gave her a dose of the quinine mixture, intending to give her the injection of beef-tea, &c. She swallowed the dose without trouble, but in a few seconds rose straight up in bed, gasping; in half-a-minute after she fell back on the pillow and ceased to breathe. I at once started artificial respiration, but only succeeded in getting respiratory attempts for a few moments, failing to rouse the heart's action in the least.

The dog was shot the same evening, so we were unable to get accurate information as to its state.

I must here express my obligations to Dr. Dolan for his suggestions, and also my friend Dr. Tatham for his assistance in the treatment of the case.

*Remarks by T. M. Dolan.*—This was an unmistakable case of hydrophobia. There was the well-marked facial expression I have seen in seven other cases, and which word-painting cannot adequately describe. The symptom of inhibitory spasm was well-marked. Consciousness was unimpaired, and the woman was wishful and anxious to get better, though not knowing the name of her disease, so that she readily took the medicine offered to her in my presence. This was swallowed, but produced such convulsive twitchings of the muscles of the neck, extending instantaneously over the whole body, that she sank back exhausted on her pillow. Spitting into a glass, in order to collect saliva for experimental purposes, produced a similar, though slight, convulsive seizure. I noticed the same effect in the boy I saw at Keighley with Dr. Dobie. The quinine was prescribed for physiological reasons. In the presumed cerebral hyperæmia existing in this case, quinine, by exerting its sedative influence, by diminishing the calibre of the blood-vessels, and thus producing lowered intra-cranial pressure, seemed to me an appropriate drug, whilst the bro-

mide of potassium was given in large doses to assist. The Turkish bath could not be given, so resort was had to the vapour bath. Seeing the slight effect produced by quinine and bromide in two cases, I am afraid we shall have to search for some other medicines which will have a more potent influence on the medulla oblongata. On physiological grounds there is one medicine which I think might be tried, and in the next case which I have under treatment I shall use it. It is a direct sedative of the medulla oblongata. It produces constriction of the throat, and has been much used for disturbance of the intercranial circulation, as congestive head-ache, sun-stroke, &c., by homœopaths, by whom it is well known as glondine—better known to us as nitro-glycerine. It was first introduced by Dr. Hering, of Philadelphia, in 1850.

## Special.

FRANCE

(FROM OUR OWN CORRESPONDENT.)

**MATERNAL NURSING.**—At the Académie de Médecine M. Blache read a work entitled *Maternal Nursing*, and the advantages to be derived from it to the mother and child. After insisting on the importance of maternal nursing, M. Blache cited the following figures in support of his opinion. According to the last census in England, the increase of the population was 145 per 10,000 inhabitants. In Sweden and Norway the proportion was still greater. In these two countries maternal nursing is the rule, and thus the mortality amongst children under one year is but 13 per cent. in Sweden, and 10 per cent. in Norway. For the same year (1878) the proportion of the increase of the population was 81 in 10,000 in Switzerland, 77 in Italy, 130 in Germany, and in France 36 only.

**NERVE-STRETCHING.**—At the Société Médicale des Hôpitaux, M. Debove reported the result of an operation (nerve-stretching) he performed on one of his patients attacked with locomotor ataxy. It was well known, he said, that lancinating pains constituted one of the symptoms, the most important, of locomotor ataxy. A great many attempts were tried to ease these pains, the most abused of which were subcutaneous injections of morphine. Thus at Bicêtre there was a patient who received 16 centigrammes (3 grains) daily of morphine in injection, and still he got only momentary relief. For some time the German doctors appear to have obtained good results from nerve-stretching in the case of rebellious neuralgia. A Berlin doctor had the idea of applying this treatment to the lancinating pains of locomotor ataxy. This operation was performed on at first one sciatic nerve, then the other, and finally on both the crural; the patient immediately experienced relief, he could walk, and was almost completely cured of his inco-ordination. At the last congress of German surgeons Esmarch related the history of a patient experiencing violent pains in the inferior members, but above all in the upper, on whom the nerve-stretching performed in the axillary region gave considerable relief, not only in the upper, but also in the lower extremities. These facts tempted M. Debove to try this operation on one of his patients suffering from locomotor ataxy, and who for a long time experienced violent pain in the lower limbs. Since the operation was performed three weeks ago this patient, who has suffered for ten years, has not felt one pain, and the inco-ordination is considerably ameliorated. M. Debove found it difficult to give a satisfactory explanation of these facts; he is disposed to believe that it is the central nervous system that is acted upon.

**REBELLIOUS VOMITING.**—At the Société de Biologie a member considered that in the case of rebellious vomiting, that the submission of the interior of the stomach to the influence of electricity, effected by one wire of a battery conducted into the stomach by means of an œsophageal sound, gave good results. He had been able after fifteen sittings to arrest vomiting, for which everything else was tried in vain.

**USE OF IODOFORM IN GERMANY.**—Iodoform is gaining partisans amongst gynecologists in Germany, especially it has been used with the best results in the treatment of

chronic metritis, perimetritis, and ulcerations of the cervix. Iodoform is applied in these cases under the form of plugs dipped in a solution (one in ten of glycerine), or as a pomade. It has shown itself greatly superior to tincture of iodine. It has also the advantage of speedily allaying pain. The introduction of the plug may be resorted to twice a week, and to act more quickly and effectually the employment of the plug should be combined with frictions of a pomade of iodoform upon the abdomen.

**BROMIDE OF POTASSIUM IN VESICAL CATARRH.**—An Italian doctor has published the effects of the administration of bromide of potassium in vesical catarrh. He considers that this medicine acts promptly and effectually in this affection. In the cases he had treated he had never observed any eruption due to the exhibition of the salt.

**ACUTE RHEUMATIC FEVER TREATED BY ERGOTINE.**—M. Chevallereau communicated two cases of acute rheumatic fever treated by subcutaneous injection of ergotine, at the meeting of the Société Clinique. These cases are, I esteem, worth giving in full. The first was that of a young girl, *æt.* 23, who was attacked with acute rheumatism, occupying especially the right side, shoulder, elbow, hip, knee, and ankle, being all engaged, the pain being very violent. The day the author visited her he injected into the right thigh ten drops of a solution of ergotine (*yyon*) which had diminished the pain in a marked manner, but the patient dreading the momentary pain of the little hypodermic syringe, M. Chevallereau was unable to make the second injection until three days afterwards, when the amelioration was very rapid and sensible. Nine days afterwards or twelve days after the first visit the cure was complete. The second case was that of a little girl, *æt.* 9, of a strumous disposition. On his first visit M. Chevallereau injected eight drops of the same solution of ergotine. Two days afterwards on his second visit the pains were found to have completely disappeared. There was still a little swelling in the right wrist. A second injection was made, and three days afterwards the child was able to be out. The author concluded by attributing the rapid cure in the above two cases to the action of the ergotine, as no other treatment was employed. A friend of mine told me a day or two ago that he was called to a case of acute rheumatism, the subject being a man, *æt.* about 60, and, imitating M. Chevallereau, he injected the ergotine in the right thigh. The effect was almost magic. The next day the swelling, which was considerable, especially at the wrists, had disappeared, and the pain was almost *nil*. It is not always easy to procure a proper solution of ergotine, but the following, which I give on the authority of Moatard Martin, may be depended upon: Ergotine, ʒss.; glycerine, water,  $\text{āā}$  ʒss. This solution keeps any length of time, and has the advantage of being easily prepared. The amount to be injected is from fifteen to twenty drops.

## REPORTS OF MEDICAL OFFICERS OF HEALTH.

### BOURNEMOUTH.

FROM the report of the medical officer of health for this fashionable health resort, we learn that the death-rate included 123 deaths amongst visitors; the resident death-rate being estimated at 12 per 1,000. There was one fatal case of small-pox, and four of scarlet fever, and singularly 14 deaths are attributed to whooping-cough. We trust that the pine trees of Bournemouth will not be cut down, as they contribute materially to the value of this place as a health resort.

There is an excellent regulation here in force at the day schools. A medical certificate is required from all children who have had infectious diseases before they are again admitted. This is a practice worthy of imitation.

### NEWCASTLE-ON-TYNE.

Mr. Armstrong is certainly a hard-working medical officer of health, and his report, with his colour disease charts, plans, and maps, is an excellent example of what a report should be. The conditions of a town like Newcastle are very different from that of a sanatorium, and looking at the

death-rate, we find that it reached 23·5 per 1,000, including 562 deaths from diseases of the respiratory organs.

Infant mortality was lower than in former years, reaching 784, against 888, 842, 971 in the preceding years.

We were very much struck by reading that only 38 cases have been sent to the hospital, and that only 8 scarlatina patients were received, especially since we learn that 284 deaths occurred from scarlet fever, and 33 from enteric fever. It is quite evident that the public do not appreciate Mr. Armstrong's advice, contained in the last part of the report, or the fever hospital would have been more used. Zymotic diseases cannot be extinguished unless the public assist the work of isolation; and if the first few cases of scarlatina were sent to the fever hospital, the disease would be checked in the initial stage, and much suffering would be prevented.

In most of the reports we notice the same facts about the use of fever hospitals. There is evidently a great repugnance to send children from their homes. This is an unwise prejudice detrimental to the health of the community.

Medical officers of health will have to beat it down, it can only be achieved by such a method of education as Mr. Armstrong adopts.

Compulsory notification of infectious diseases and compulsory removal will have to be adopted if the public do not awaken to their true interest in this matter.

## The Mineral Waters of Europe.

### THE "MEDICAL PRESS" ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, &c.

WITH

### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P.Lond.,  
Lecturer on Materia Medica and Therapeutics at the London  
Hospital, Physician to the Hospital for Diseases of the  
Throat, &c.

(Continued from page 12).

*Pullna Water.*—Clinical experience has shown us that this is similar in action, but more powerful, than Friedrichshall. The writer had, however, found that its greater activity had been rather overstated, and was scarcely equal to what might have been expected from the amount of salts. This discrepancy is explained by the new analysis, which shows Friedrichshall to contain more than was previously supposed. Comparing the analyses now furnished, we find Pullna, with less total solids (as 112 to 192·4) has more purgatives in the proportion of 104·5 to 84·7. It has also nearly three times as much antacids, but the total amount of these is of little import. The alleged presence of lithium is shown to be a fallacy; but far more important is the discovery that the bottled water now in the market is contaminated with organic impurity. The owners should take the hint, and at once set their houses in order. We confess we shall be more disposed to employ one of the other waters, especially for long courses, until this impurity is got rid of.

*Dose.*—Three to five ounces as an occasional purge for adults. For continuous doses a wineglassful, to be mixed with warm water, and taken before breakfast.

*Rákóczy* is twice as strong as either of the preceding waters, containing 200 grains of purgative salts in the half-pint, as against 104·5 in Pullna, and 84·7 in Friedrichshall. It is therefore well adapted when a more rapid laxative action is desired, especially as an occasional purge. It is a very useful family medicine, and the dose is smaller than that of the less concentrated waters. Sufficient hot water may therefore be added to raise it to as high a temperature as can be comfortably drunk, without at the same time making the dose too bulky. Then the considerable percentage of lithia in this water makes it specially appropriate for gouty and rheumatic patients, who may require a saline purgative. In the numerous disorders attributed to hepatic derangement, in lithiasis, and as a promoter of tissue metamorphosis, it may also prove useful. A little iron and a trace of fluorine discovered by Mr. Tichborne may also give some peculiarity to this water. For continued use the quantity taken should be small, and gradually decreased. We do not often advise it in this way unless as a supplement to a course of less powerful waters, such as Leamington or Cheltenham, and for this purpose it is very useful.

**Dose.**—As an occasional aperient, half-a-wineglassful to a wineglassful diluted with hot water first thing in the morning, followed by a cup of tea. For continuous use a less quantity may be taken, either at bed-time or in the morning, diluted with hot or cold water.

*Hunyadi János* is only a little weaker in salts than *Rákóczy*, is equally antacid, and may be given in similar doses and for similar purposes. But it contains no lithia, and therefore has not the special indication furnished by that alkali. On reference to the analyses it will be seen that this water contains very much less magnesium sulphate, but only a little less total purgative salts than the last, inasmuch as there is a larger proportion of sodium sulphate.

**Dose.**—As an occasional purgative half-a-wineglassful to a wineglassful, with an equal quantity of hot water before breakfast. For continuous use the dose should be gradually decreased, and it may be taken either at bed-time or in the morning, as the patient prefers.

*Aesculap Hungarian Bitter Water.*—The analyses in the last report show that this water is related to *Rákóczy*, but is rather weaker, containing ten grains less of solids, but only five grains less of purgatives. It is three times as rich in antacids, but it contains no lithia. Its proportion of magnesian sulphate is higher than the soda salt, of which it contains less than either of the Hungarian waters named. It contains, however, nearly three times as much chloride of sodium, and so approaches nearer those waters in which this salt is an important ingredient. Its uses will be readily recognised from what has preceded.

**Dose.**—As an occasional aperient, half-a-wineglassful to a wineglassful, diluted with hot water, first thing in the morning, followed by a cup of tea. For continuous use a less quantity may be taken, either at bed-time or in the morning, diluted with hot or cold water.

*Matton's Royal Hungarian Bitter Water.*—The chemical characteristics of this water have been already stated, and supply sufficient information respecting it.

*Seidlitz.*—This is a weaker water, containing only 61 grains of purgative salts in the half-pint, and yet this is sufficient to have obtained for the spring a high reputation which lasted many years, though it is now comparatively fallen out of use. Our chemical colleague finds it contains a good deal of sulphate of sodium, though other analyses do not mention this, and accordingly its action has hitherto been attributed entirely to magnesium sulphate, of which it contains much more.

*Saidschutz.*—From the same district as the last-named water is a little stronger. The analysis of Berzelius (quoted p. 394) assigns a larger proportion of nitrate of magnesia to this than to any similar water.

*Birmensdorf* is an excellent bitter water containing also the mixed sulphates but the magnesium salt greatly preponderating, though there is enough soda to give it some character. It contains more sulphate of magnesia than Friedrichshall or Pullna, but less than *Rákóczy* or *Hunyadi János*. On the other hand it has less sulphate of soda than either of them. It will thus be found useful when either of the other bitter waters are found rather too powerful, and may often be preferred when it is desired to continue the use of a purgative water, and the Epsom salts not contraindicated.

**Dose.**—About half-a-tumblerful diluted with warm water.

*Other mixed Bitter Waters* may be mentioned. Some, as *Kissengen* and *Uriage* may be almost regarded rather as salt waters with a small quantity of purgatives. The glory of the *Epsom* spring has departed, but its fame has fixed its name on the chief ingredient of the majority of purgative waters. Other English spas, as *Beulah*, *Streat-ham*, *Purton*, *Scarborough*, and above all *Cheltenham*, belong to this class, and are deserving of more attention than they now receive, especially as the waters when found not strong enough can be reinforced with one of the stronger importations, as we have already pointed out. *Cheltenham*, too, might well be preferred as a residence for a season to many foreign resorts, and between its climate and that of *Scarborough* the majority of patients needing such a course of saline purgatives as we have described might be well suited.

*Leamington* is another beautiful resort, but its waters contain no magnesium sulphate, and therefore more properly belong to our next group, the efficacy of which is due to Glauber's salts.

THE Board of Trinity College, Dublin, has granted the degree of Bachelor in Medicine (without fees) to Mr. John Charles Martin, for distinguished success in having obtained double first place at the recent examinations for medical and surgical degrees,

# Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 14.

The President, Dr. E. HEADLAM GREENHOW, F.R.S.,  
in the chair.

Mr. CROFT narrated a

## CASE OF HYDRONEPHROSIS OF TRAUMATIC ORIGIN.

A boy, *æt.* 12, was admitted under his care in St. Thomas's Hospital on June 3, 1880. On the previous day the boy had hurt his left side and hip by falling across a companion's back whilst trying to jump over him. This was followed by pain and hæmaturia, for which he was brought to the hospital. The pain in the left lumbar and hypochondriac regions continued, and the hæmaturia extended over five days. After that period the pain subsided, and the urine remained free from blood. The patient had never had any previous tumour in that region, or disease of the urinary apparatus. He was discharged on the 16th day to his own home. Twenty-two days after his return home, and thirty-nine days after the accident, he was brought back to the hospital, as he was suffering much discomfort in his side from a swelling, and he seemed very ill. This was on the 9th of July. Five days later he had become drowsy, though easily roused. He said he could not see bystanders, though he distinguished light from dark. His tongue was furred, and he had no appetite. The temperature was sub-febrile. The tumour, which distinctly fluctuated, extended through the lumbar region and left hypochondriac region into the epigastric and umbilical regions, causing the abdominal walls to project considerably. On the three preceding days the total amount of urine collected in twenty-four hours had been fourteen, eighteen, and twenty ounces respectively. On this date the swelling was aspirated, and seventy-nine ounces of urine-coloured fluid were drawn off. The fluid had a *sp. gr.* of 1008. It did not contain any blood or pus, but yielded to heat a trace of albumen. During the next three days twenty-five, twenty, and thirty-five ounces of urine were collected on each respective day; on the fourth day fifty-one ounces were collected, and on the fifth day twenty-five ounces. On the eighth day the swelling had re-assumed a large size, and it was therefore re-aspirated, and thirty-eight ounces of the same sort of fluid were drawn off. Nine days later it required re-tapping, and then sixty-two ounces were obtained. The specific gravity of the fluid was 1005, and contained a little albumen. Between this occasion, July 29th, and Oct. 15th he was tapped five times, more than three pints and less than four pints being drawn at each operation. At the last or eighth tapping the fluid was found to contain a large proportion of albumen. Since that date no further collection of fluid has taken place. No swelling was discovered after that date, and there is not any swelling now. His general health improved steadily after the relief afforded by the first tapping. The daily quantity of urine passed after that first tapping was observed to become increased, but no large and sudden changes were found in the amount passed at any period of his illness, and no morbid products manifested themselves in the urine, which he passed naturally. With regard to the origin of this morbid collection, Mr. Croft conjectured that at the time of the accident a lesion of the pelvis took place (not leading to extravasation of urine) at or above its junction with the ureter; and that the lesion was followed by the adhesive form of inflammation, and as a consequence obliteration of the communication with the ureter. He inclined to the view rather than to the hypothesis that the kidney itself was the seat of the lesion, but the succession of events in the case were in his opinion more consistent with total obstruction of the excretory tube than with disturbance of the excretory organ. The possibility of its being cystic in its origin was briefly considered but negatived. The author referred to the classical cases of Mr. Stanby, recorded in the *Med. Chir. Trans.* for 1844, but as one case was only to a slight degree similar in character to the one just narrated, and the other was dissimilar, they were only briefly adverted to. He presumed that the boy was permanently cured, and that the kidneys, at the side of the injury had undergone atrophic change.

Mr. HEATH said he thought the explanation of a lesion insufficient to account for the progress of the case, the time

allotted to recovery being too short in duration. He suggested that the origin of the injury might have been a small calculus impacted in the ureter, experience pointing to this cause in producing cystic tumours of the kind described. On the removal of the calculus by natural means, the symptoms abate, and rapid recovery ensues. He inquired whether the bladder had been carefully examined.

Mr. CROFT replied that the idea of a calculous origin had been entertained, but no account of any previous mischief to the bladder could be elicited; or of any indications pointing to a calculus in the ureter. The report of the quantities of urine passed showed a gradual decrease in the amounts; and following relief of the urgent symptoms there was nothing to lead to the supposition that a foreign body existed in the bladder.

Dr. LLOYD read notes of

## TWO CASES OF MYXŒDEMA.

Hannah Wall, *æt.* 35, unmarried, had enjoyed good health till within the last five years. Menses regular, but occasional leucorrhœa. Father died at 59 of dropsy and heart disease; the mother now alive, *æt.* 70, but suffers much from rheumatism, and is nearly blind. Brother and sister both healthy. Five years ago H. W. began to feel severe pain in both legs, and could rise with difficulty after sitting down, and movements were slowly made. Appetite also failed. Swelling under left eyelid appeared four years ago; twelve months later pain was felt in the neck, and the voice underwent a marked change, becoming rougher in tone. The memory was likewise impaired. At present the patient has a peculiar expressionless look; the whole face seems swollen; the eyelids puffy; nose enlarged and red. The skin is translucent and red; the superficial vessels much dilated in spots about the face. The hair of the scalp is dry, hard, and scanty. She never perspires. Speech is thick, and slowly uttered, with nasal intonation. The features are devoid of all expression, the mouth almost resembling a slit. Post-mortem examination of a second patient who died in May last, and who was dropsical for a length of time preceding death, showed the body to be much emaciated, the lower extremities swollen, but without marked pitting on pressure, except in the left leg. The skin over the belly was tense and shining, with tendency to desquamation of the cuticle, and purpuric patches on the dorsum of the forearm. The superficial vessels of the face were distended; hair of the scalp dry and scanty; subcutaneous fat yellow and moist, but did not collapse; 240 ounces of brown-yellow fluid were drawn from the abdomen, and patches of ecchymoses were everywhere found. The great omentum was glued to the parietal peritoneum. The kidneys were in a state of cirrhosis. The left pleura contained a pint of clear fluid, and presented a few old adhesions. The right pleura contained fluid, but no adhesions were present. Pericardium held half a-pint of clear yellow serum. The left ventricle was hypertrophied; the mitral and aortic valves thickened; no regurgitation. The dura mater firmly adhered to the bone; much atheroma of the vessels at the base of the brain; the convolutions were flattened; the right hemisphere was especially atrophied; ventricles normal.

Mr. HULKE suggested that the progress of the second case might have been influenced by the renal and cardiac complications.

Dr. ORD explained that he had seen both the cases, the last but a few days before death. The patient shown that night, exhibited all the special features of myxœdema in a marked manner. Skin dry and inelastic; hair scanty; contrast very marked between the cheeks and eyelids, the former red, the latter pale and tumid; no pitting in any parts; speech slow, uncertain, with nasal intonation; urine normal, except that it contains a minute amount of albumen; temperature below normal, and the gait peculiar and staggering. In the other case, which was, when seen, in the last stage of the disease, the skin was wrinkled and movable on the parts below. The cerebral or renal symptoms may be assumed to supervene on this condition. The heart was found to be hypertrophied; ascites was well developed. Several of the tissues had been prepared for examination; the spinal cord was especially interesting in connection with the question whether the nervous system underwent degeneration in such cases, or whether the altered sensibility was dependent on the mere interposition of a tumoid pad between the nerve fibrils. The spinal cord was found not to be sclerosed, but there was a general increase of connective tissues in all parts, the walls of the vessels, and of the central canal, sharing extensively in it. There was

however, no degeneration of the purely nervous structures.

At the suggestion of the President, Dr. Ord undertook, in conjunction with Dr. Savage, to draw up a report of the microscopical appearances when all the tissues in hand had been fully investigated.

Dr. ANDREW CLARK said that since 1870 he had been familiar with the class of cases so well described by Drs. Ord and Duckworth under the name myxœdema, and three years ago entrusted Dr. Burnett with the arrangement of the facts he had collected, but which were not yet ready for publication. He had had no experience of the post-mortem appearances these cases presented, but so far his observations of living subjects of the disease exactly corresponded with that of Dr. Ord. The majority, however, were males, and there was a strong personal likeness among them, produced as a feature of the complaint. The skin in all was dry and translucent, the eyelids swollen, hands puffy, and all complained of a feeling of being "bound" in the muscles. A weak heart—sometimes with a murmur, sometimes not—is found in every subject of the disease. The urine is of low density, and almost all are the subject of cerebral affections, producing change of intonation with low-pitched voice, amounting in women to a falsetto. Inability to move freely in the dark invariably attended the disease, and peculiar nerve symptoms as commonly made themselves apparent. Dr. Clark imagined the stages of the disease to be marked by (1) affections of the nervous system, (2) renal inadequacy, and (3) affections of the circulatory system.

Dr. ORD remarked that the quantity of urine passed was much below the average, in certain cases.

The PRESIDENT said he had seen several cases of myxœdema, but that until Dr. Ord first described them he did not understand them. In one case, however, within his experience, there was found distinct sclerosis of the spinal cord on post-mortem examination. One of the cases exhibited to the Society at its last meeting, he remembered to have seen fifteen or sixteen years ago.

Dr. LLOYD said the temperature of patients in the condition of myxœdema never exceeded 96 to 98 degrees, and might be as low as 84 degrees.

#### THE SOCIETY OF METROPOLITAN MEDICAL OFFICERS OF HEALTH, DUBLIN.

The annual general meeting of this Society was held at the Royal College of Surgeons in Ireland on Wednesday, Jan. 12, at 4.30 p.m.

The President, C. A. CAMERON, M.D., having taken the chair, and the minutes of the previous meeting having been read, confirmed, and signed, the ballot for the election of officers for the ensuing twelve months was declared open.

Some correspondence having been read, the Hon. Sec. informed the meeting that there was a small increase in their numbers, and that during the past year there had been eight meetings, at which seven papers had been read and discussed, and that these had been printed in two pamphlets and copies sent to all the members. The subjects of the various papers were as follows:—

"The position of Medical Officers of Health," by Dr. Chapman. "Some Points of Domestic Scavenging," by C. F. Moore, M.D. "Compulsory Removal to Hospital of persons suffering from Infectious Diseases," by J. F. Pollock. "Toxic Principles in Whisky," by C. A. Cameron, M.D. "Colour-blindness in relation to the Mercantile Marine, Railways, and the Public," by C. F. Moore, M.D. At two of the eight meetings no papers were read, but there were three long and important discussions, one an adjourned discussion on Dr. Cameron's paper on "Toxic Principles in Whisky;" a very important one on "The Quality of Drugs supplied to Public Institutions, and the Method of Supply;" and one on "The Proposed Legislation on the Notification of Infectious Diseases."

The Hon. Sec. congratulated the Society on its healthy financial condition.

The Hon. Treasurer then read a statement of accounts, by which it appeared that, after paying all its debts, there was a fair balance to the credit of the Society.

The President, C. A. CAMERON, M.D., then delivered his Address,

#### ON SANITATION,

which will be found on page 48.

At its conclusion a unanimous vote of thanks was passed to

the President for the interest he had taken in, and the time he had devoted to, the Society. The President briefly replied. Votes of thanks were also passed to the Hon. Sec. and the Hon. Treasurer, both of whom replied in suitable terms, the Secretary regretting that he had unavoidably to sever his official connection with the Society.

The PRESIDENT then declared the ballot closed, and the scrutineers having handed in the result of their scrutiny, the following were declared duly elected to serve during the ensuing year, viz.: *President*—C. A. Cameron, M.D. *Committee*—Drs. Chapman, J. F. Burne, C. F. Moore, Nowlan, Purcell, and Speedy. *Hon. Sec.*—Dr. Pollock. *Hon. Treasurer*—Dr. Peela.

The meeting then adjourned.

“SALUS POPULI SUPREMA LEX.

WEDNESDAY, JANUARY 19, 1881.

#### NOTIFICATION OF INFECTIVE DISEASE.

LAST week we discussed the broad principles upon which proposals to compel the medical practitioner to notify infective disease to the responsible sanitary authority ought, for the benefit of the public, to be dealt with, and we endeavoured then to make it clear that, while agreeing that an overwhelming necessity for sanitary reform might justify a sacrifice of professional interests, yet that those interests must be guarded vigilantly against any aggression not justified by such necessity. We insist that before the medical profession can be induced to submit itself to semi-gratuitous performance of duty as sanitary detectives, it must be clearly shown by those who would put us under this yoke:—

a. That the assumed benefits to public health cannot be attained without the direct and executive agency of the doctors.

b. That the proposed sanitary reform will not defeat its own object by leading to concealment of infective disease and false registration of death.

c. That the end, if attained, is worthy of the proposed sacrifice of medical interest and feeling.

Enthusiastic sanitarians and officials of sanitary authorities will, no doubt, answer all these requirements in the affirmative, and will attach very little value to professional interest and feeling as against the promotion of their own hobby, but we can assure these persons that there are good and sufficient public reasons, irrespective of professional etiquette, which make it almost paramount that a physician shall be perfectly free of every duty towards his patient save that of curing him if he can, and we say that it will be necessary to show a very strong necessity before a proposal can be accepted by which the physician may become not only the confidant and adviser of his patient, but at the same time the police officer acting for the public.

In discussing the proposal to make general in Ireland the compulsory notification of infective disease by the physician, we have hitherto confined ourselves to discussion of general principles and to warnings against possibly objectionable proposals. These proposals are now before us in a definite form, and we give them in their own words in all essential particulars. The following is the Bill introduced by Mr. E. D. Gray, Mr. Brooks, and Mr. Dawson, last week, and now standing for a second reading early in February:—

Whereas it is desirable that due notice should be given to the sanitary authorities in Ireland of the existence of dangerous infectious diseases within their district. Be it enacted, &c., as follows:—

1. Act may be cited as the Notification of Infectious Diseases (Ireland) Act, 1881.

2. This Act shall be read and construed with the Public Health (Ireland) Act, 1878.

3. Upon the application of any sanitary authority the Local Government Board for Ireland may, from time to time, if they think fit . . . declare this Act to be in force within the district or any part of the district of the sanitary authority.

4. If any inmate of any building used for human habitation in the district is suffering from small-pox, cholera, scarlatina, typhus, typhoid, puerperal, or relapsing fever, diphtheria, measles, or erysipelas, every medical practitioner attending or called in to visit such inmate, or if more than one medical practitioner is in attendance, then such one of them as was first called in, shall, on becoming aware that such inmate is suffering from any such disease as aforesaid, forthwith fill up, sign, and deliver, or cause to be delivered or transmitted by post to the sanitary authority, a certificate, stating, according to the forms contained in the schedule to this Act, the name of such inmate, the situation of such building, and the name of such occupier or person, and the nature of the disease from which such inmate is suffering.

5. If no medical practitioner be attending on or has been called in to visit such inmate, the occupier, or any other person having the management or control of such building, or if such occupier or other person be prevented by disease or otherwise, the person in charge of such inmate shall, as soon as he shall become aware of the existence in any such inmate of any such disease, forthwith cause notice thereof to be given to the sanitary authority at their office, in the form contained in the schedule to this Act.

6. The sanitary authority shall supply gratuitously to every registered medical practitioner resident or practising in the district forms stamped for transmission through the post, for the certifying by such medical practitioner of the particulars herein-before mentioned of such cases of infectious disease attended by him, and the authority shall pay to every medical practitioner who shall, in pursuance of this section, duly give any such certificate a fee of *one shilling* in respect of the same, provided that more than one fee shall not become payable under this section within an interval of *thirty days* to the same medical practitioner for certificates

given by him in respect of the same disease occurring in the same building; provided also, that in the case of work-houses, gaols, and public hospitals, no such fee shall be payable.

7. The sanitary authority may, from time to time, by resolution, subject to the approval of the Local Government Board, order that any other acute infectious disease, in addition to those above mentioned, shall be deemed to be within and subject to the provisions of this Act.

8. Any person neglecting to give or deliver, or cause to be given or delivered, any notice required to be given under this Act, shall be liable to a penalty not exceeding *five pounds*, to be recovered in the same manner as penalties under the Public Health (Ireland) Act, 1878.

#### FORM OF NOTICE.

#### NOTIFICATION OF INFECTIOUS DISEASES (IRELAND) ACT, 1881.

"Pursuant to the above-mentioned Act, I hereby certify and declare that, in my opinion, the under-mentioned person is suffering from a disease within the terms of the said Act.

"Dated                      day of                      18

"(Signed)

"Medical practitioner, duly registered.

"1. Name of person suffering from the disease.

"2. Situation of the building wherein such person is.

"3. Name of occupier or other person having the management or control of the building.

"4. Nature of the disease.

"To the sanitary authority of                      ."

We leave this measure to the temperate and unprejudiced consideration of the profession in Ireland, but in doing so we must point special attention to the following facts:—

Firstly, the Bill applies not only to Dublin, but to every sanitary authority in Ireland, and, so being, must be looked at from the differing points of view of town and country.

Secondly, the Bill is entirely permissive, and the sanitary authority may or may not adopt it. It will, therefore, if passed, be certainly put in operation in Dublin, but as certainly will be a dead letter in most country districts, and we shall, therefore, have different sanitary laws (on the subject) in various parts of Ireland.

Thirdly, the extent of the responsibilities of this Bill must be judged, not by the simple fact that notification of infection is to be compulsory, but by the consequential effects of that notification upon the house occupier, the patient, and the physician. Those effects are set forth in the sections of the Public Health (Ireland) Act, 1878, which set forth the part which the sanitary authority is to play on receiving the notification. We shall give these sections next week, and refrain from doing so now lest it might be supposed that we are seeking to provoke hostility to the Bill by exaggerating the inconveniences to the house occupier which the enforcement of sanitary precautions may involve.

Fourthly, the Bill adopts the proposal that the physician shall, when he leaves his patient, notify directly to the sanitary authority, and does not adopt the milder suggestion that he shall hand his certificate to the house occupier, and leave that person to do the rest.

Lastly, the Bill proposes a fee of *one shilling* for the delivery of the certificate; obliges the physician to notify any number of cases occurring in the same house for a whole month for that shilling; refuses him any fee for the trouble of such notification in public institutions; provides no fee for his attendance in Court, if he should be obliged to prove his certificate; and proposes to fine

him five pounds if he omits any part of the assigned duty.

We invite our Irish readers to think over this proposition of law, and to express themselves freely thereon. An opportunity has been given them to do so by the Irish Medical Association; and we would remind them that, if they refrain from expressing their minds as to these proposals, they must not complain afterwards if their responsibilities are irksome, or prejudicial to their interests.

### THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

It is stated that when things get to the worst there is always some hope of a change for the better. The truth of this adage appears about to be exemplified in the case of the Fellowship of the Royal College of Surgeons of Edinburgh. For some years there has been a growing feeling amongst many of the Fellows that the admission to the Fellowship had become a public scandal. An attempt was made by Mr. Annandale in 1876 to repair the damage done by the increasing sale of the diplomas, but owing to motives that cannot be too closely scanned, Mr. Annandale's proposals met with unmerited failure. The last attempt is that by Mr. Chiene on whose proposal a committee was formed to make an investigation into the college rules, and to propose such measures as they deemed necessary to put the Fellowship on a better footing. Before discussing the proposed alterations we must make a few remarks to enable our readers to understand the position of affairs. By a Royal Charter, granted in March 1851, the admission to the Fellowship is required to be by ballot, so that, as the law now stands, another charter would have to be granted before the admission by the ballot could be done away with, thus incurring expense and probably much opposition. Another obstacle to reform is also found in the fact that although the College almost petulantly repudiates the idea of its being a teaching body, it yet requires all lecturers and teachers in the extra-mural school to become its Fellows before granting them on examination a license to teach. Now this is no small difficulty, for a lecturer on *materia medica*, for instance, would doubtless feel aggrieved to have to pass an examination for the Fellowship, and another in his special department, before being allowed to teach. But to return to the reports. Mr. Annandale proposed two classes of Fellows—"Honorary Fellows," and Fellows by Examination. The former were to be members or licentiates of any recognised college of surgeons who had been in practice for not less than twelve years, to be seconded by two Fellows, and to pay a fee of not less than £45. The latter might be students of medicine showing certificates of good general education, and then pass two examinations—the first in anatomy, physiology, and chemistry; the second in the principles of surgery, clinical and operative surgery, surgical anatomy, pathology, and jurisprudence. The fee was to be £30. After these examinations the successful candidates were to be submitted to the ordeal of the ballot in terms of the charter. One of the objections against these proposals can scarcely be read without rubbing one's eyes. It is as follows:—"It would thus seem, under these cir-

cumstances, to be a work of supererogation to add another examination for the Fellowship. It is difficult to see how a standard of examination higher than that for the licence could be instituted, or, if instituted, could be stringently enforced." Mr. Chiene's committee also propose two classes, Fellows by examination and ballot, and Fellows by ballot, without examination, but no notice is taken of intending teachers in the medical school. The examinations are to be less stringent than those proposed by Mr. Annandale, the fees being also somewhat less than formerly suggested. The proposals of the committee are likely to meet with considerable opposition. Whatever may be the result of the deliberations at the meeting in February, two things are self-evident—that the present system of admitting candidates to the Fellowship cannot much longer be sustained; and that, if any examination is proposed, the income of the College will suffer considerable diminution—a result admitted by the committee themselves. Who will then take the Fellowship it is difficult to conjecture, for it is now chiefly taken by practitioners resident in England, either licentiates of the Edinburgh College or members of the London. In England, by a not altogether pardonable omission, the "E" or "Ed." is not written, and the Edinburgh Fellowship is passed off as the English. For what other object English residents can take the Edinburgh Fellowship it is difficult to understand, for it carries no weight with it in England; and, besides the use of the letters, non-resident Fellows have none of the social advantages such as the small band of some twenty-five or thirty Fellows, meeting quarterly in Surgeons' Hall to elect Fellows, enjoy. What are the causes that have been at work to reduce the Licentiate and Fellowship to their present standard it is not for us to inquire, but it is well known that Scotch students rather go to the expense of a visit to London than take the licentiate of their own college; and were it not for the double qualification there would scarcely be a licentiate except from that class of students who go the round of the examining boards in the hope of at last finding a resting place. We sincerely hope that something may be done to put the ancient College of Scotland on a better and more honourable footing.

### Notes on Current Topics.

#### Typhoid Fever in the Garrison of Portsmouth.

It appears that between the 30th of September and 10th of October last seven cases of fever designated *enteric* occurred in the Cambridge Barracks, Portsmouth. In the account of that outbreak before us the distinct significance to be attached to the term *enteric* does not appear, neither are particulars given as to the previous history and condition of the individuals affected, except in regard to one point, namely, that they all used milk obtained from a particular dairy, and that after they ceased to obtain milk from it there occurred no further cases of that fever among them. Now, here is an abstract, taken from the report before us, of the evidence upon which the conclusion has been arrived at that the cause of fever in these instances was the milk, the words itali-

cised being so in order the more distinctly to indicate the measure of their importance, namely—The milkman's son had been suffering from *some kind of fever with typhoid* (dynamic ? or is the term used as a synonym of enteric ?) symptoms. It seems probable that the infection may have been absorbed by the milk, which appears to have been exposed in the apartment in which he lay sick. If, however, as seems likely, the person employed in milking was also in attendance on the patient, the chances of the poison getting into the milk would be enormously facilitated. It would be satisfactory to learn whether or not the fever from which these seven persons suffered was looked upon as specific in its nature ; also the precise grounds upon which, from what really look like so many assumptions, the conclusion has been arrived at that the cause of disease was milk, and nothing else than milk. We are of opinion that information on these points would be of considerable value in a professional point of view.

#### Death from Rupture of a Varicose Vein.

THAT an ignorance of elementary physiology often leads to the sacrifice of human life, was painfully illustrated at an inquest held last week before Mr. Coroner Flint, at Burton-on-Trent, on the body of a married woman, named Sarah Newman. It was given in evidence that this woman had suffered for a long time from extreme varicosity of the veins of the legs, for which she had always declined to take medical advice, although frequently expressing the apprehension that the dilated vessels would burst some day and kill her. On the night of the 8th inst., as she was getting into bed, her fears were realised, a varicose vein giving way just below the knee. Her husband, who was with her at the time, instead of taking any prompt measures to arrest the hæmorrhage, went across the road to fetch her mother, who, on her arrival, bandaged the leg with a piece of a sheet. By that time, however, a large quantity of blood had been lost, and death from exhaustion took place three-quarters of an hour after the rupture. The doctor was brought about half-an-hour after the patient's death. Not without justice did the coroner remark that, if anyone had pressed a thumb on the wound until medical assistance arrived, the woman's life would have been saved. He might have added that, if medical assistance had been sought timeously, no wound would ever have occurred.

#### Some Important Uses of Amyl Nitrite.

THE editor of the *Alienist and Neurologist* gives the following uses for this agent :—

Differential diagnosis of cerebral hyperæmia and anæmia.—Although it is not difficult to distinguish marked forms of these opposite cerebral states, yet there are instances where they sometimes present, even to the neurologist, so many negative evidences that any additional sign that may aid in clearing away the doubt is an actual gain in our means of diagnosis. This sign we have found in the action of nitrite of amyl inhalations, in the minimum doses. In the markedly anæmic, a single five-drop inhalation does not produce cephalalgia or any considerable amount of head uneasiness or suffusion of the face, while in the decidedly hyperæmic the sense of fullness of the head, and even

of cephalic pain, is often exaggerated and very persistent even after one inhalation, the face also flushing more readily and extensively.

As a therapeutic agent in anæmia and imbecility.—The known property of this agent in quickening the cerebral circulation induced us to employ it by inhalation in the treatment of cerebral and spinal anæmia, and in the management of some imbecile patients. One little patient with very feeble head circulation, sluggish mental action and weakened power of control over the lower limbs, is now evidently being benefited by it conjoined with electricity and internal treatment. Two of our chronic aphasics are also on trial with it, conjoined with other medication, with a view of diminishing the area of possible arterial obstruction within the brain.

#### Treatment of Painful Callus.

PROF. GOSSELIN, of Paris, observes that when the pains which have their seat in the callus of a fracture are of a neuralgic origin, we should treat them by blisters or cutaneous revulsives, and especially by the tincture of iodine. Hot or cold douches, or sulphurous douches, or frictions with a chloroform liniment may also be had recourse to. Finally, a roll-bandage with wadding is of undoubted utility, diminishing the pain sensibly by saving the limb from the little shocks which keep up the painful condition.

#### On the Digestive Power of Figs.

IN the *Comptes Rendu*, xci, Prof. Bouchut speaks of some experiments he has made, going to show that the milky juice of the fig tree possesses a fermentative power of a digestive character. Having mixed some of it with a preparation from animal tissue, he found the latter well preserved at the end of a month. This fact when brought into connection with Prof. Billroth's case of cancer of the breast which was so excessively foul smelling that all his deodorisers failed, but which on applying a poultice made of dried figs cooked in milk, the previously unbearable odour was entirely done away with, gives an importance to this homely remedy not to be denied.

#### Regimental Surgeons in the French Army.

IN these days of *unification* and disestablishment of medical officers in our army, it is pleasant to find that elsewhere the position of regimental surgeons remains unchanged by that spirit of *reorganisation* which for some years back has more or less completely upset and destroyed all military establishments as they had grown up to meet the requirements and purposes of the service of this country. In the French army, although in times of war all hospital establishments are on the *general* system, and in times of peace all the sick except such men as are only trivially ill, are sent to general hospitals, yet to each battalion there is attached as belonging to it a medical officer, to whom are entrusted the numerous duties incidental to that position, as laid down in an elaborate code of instructions for his guidance. With regard to him the *Daily News* pleasantly discourses in this wise :—

"The médecin-major is certainly a general favourite in the regiment. He knows a good many odd secrets, and keeps them with much prudence and good nature. He is

everybody's friend, and is in nobody's way because he does not bar the promotion, or carry off the kudos, of other officers. Then he tells a good story, perhaps sings a good song, and plays a better game at dominoes than anybody except the colonel, who cannot safely be beaten in accordance with the rules of the service. He will grant sick certificates in a friendly way whenever it is at all decently possible to do so, and often gets a subaltern out of an awkward scrape by laying him up in lavender till the wrath of his commanding officer has blown over. He is the universal arbitrator and president of all duel cases, and generally renders them harmless when consulted in time. With respect to medical and surgical questions, he appears to be in want of rest. He has been so badgered by examiners and superiors that the thing in which he most delights is repose. It is darkly hinted in the ranks that he always prescribes the same remedy. He is a very round and mellow man, and a small fundholder, though not much given to saving or self-denial. One thing, however, is quite certain—he is an officer of scrupulous honour, and there is not a franc of his little property but could bear the light and look well in it."

#### Clinical Society of London.

THE annual general meeting of the Clinical Society was held on Friday last, when the report of the council was read, and officers for the ensuing year were elected. The report described the condition of the Society as very flourishing, the number of members reaching to 267, in addition to 58 non-resident. The balance sheet is highly satisfactory, showing a balance of £131 14s. 7d., notwithstanding the heavy expenses incurred with the recently issued volume of transactions, by far the largest and most important of the thirteen annual volumes yet printed. The Council regretted that two reports of committees, that on hip-joint disease, and that on hyperpyrexia in acute rheumatism, had not concluded their labours in time to have their reports issued before the general meeting took place. The Council concluded their report by congratulating the members of the Society on its prosperous state. The result of the ballot which took place during the evening was the election of Prof. Lister as president of the Society in the room of Dr. Greenhow, whose two years of office have expired; other changes in the list of office-bearers also took place, among them being the election of Mr. Hayward in place of Mr. Howard Marsh as secretary. Dr. Andrew Clark in an eloquent speech moved that the thanks of the Society be accorded to Dr. Greenhow for his valuable services rendered to the Society during his tenure of office as president. This having been seconded by Mr. Barker, was carried enthusiastically. Dr. Greenhow in responding referred to the attempt he had made to forward the committee work of the Society, and urged the necessity and value of such labours as had been accomplished in this connection. Several other votes of thanks were carried, among them being one to the retiring secretary, Mr. Howard Marsh, whose efforts on behalf of the Society made the compliment a richly deserved one.

#### Royal College of Surgeons of England.

ON Thursday last the quarterly meeting of the Council of the Royal College of Surgeons of England was held,

when the examination committee presented their report. In this it is recommended that the arts examination, conducted under the College of Preceptors, be discontinued after December, 1881; and further, it is suggested that the General Medical Council should be reminded of the necessity for consulting the convenience of candidates at the various examinations to be approved by the College of Surgeons in place of that it is about to disestablish. The adoption of the following resolutions was likewise recommended by the committee:—“(a) That a certificate of registration by the General Medical Council shall entitle a candidate to commence his professional education, whether for the membership or fellowship of the College, at any time after the date of such registration. (b) That the Council reserve to themselves the right of determining the conditions of admission to examination for the diploma of the College in the case of any colonial, Indian, or foreign student not registered by the General Medical Council; and (c) That, in future, candidates for the diploma of Fellow be not required to undergo any preliminary examination beyond that required for the diploma of Member of the College.” The report was adopted entire.

#### The Navy Health Report.

THE Annual Report of the Health of the Navy, for 1879, has just been issued. It records that 32.9 were invalided and 44.98 constantly sick per 1,000 of the average strength. The deaths were 8.58 of the same number. These figures show a reduction on the decennial average, and the reduction was observed on all foreign stations except the south-east coast of America, and west Africa and the Cape. The Zulu war, however, should be taken into account in this connection as having been instrumental in raising the mortality. It is to be desired that the returns presented in these reports may be compiled, if not more accurately, at least more with regard to comprehension, for the really valuable information they contain is in the present form often almost inaccessible. It is interesting to note that the younger men afford the higher percentage of hospital cases, and it justifies the thought whether the recruits for the navy are always judiciously selected.

#### Reward to a Surgeon.

THE Albert Medal of the second class has been conferred on Henry Grier, Surgeon, Army Medical Department, in consideration of his unselfish devotion in the practice of his professional calling. Lieutenant Graham, of the 10th Regiment, being in danger of death from diphtheria, in August last, Mr. Grier performed tracheotomy, and then applied his own mouth to the wound to restore respiration. The patient unfortunately died, and the surgeon sustained no ill consequences. For this act the medal has been conferred.

#### An Epidemic of Scarlatina.

A SEVERE epidemic of scarlatina is at present prevailing in Halifax, Yorkshire. We believe we are within the mark when we state that upwards of two hundred cases are under treatment. The disease is attributed by some to the milk supply from a particular farm; and as this very useful domestic article is not unfrequently fixed upon

as an easy and probable solution of zymotic difficulties, we are glad on this occasion to be able to protect its oft-smiled interests, by stating that we are informed on reliable authority that such a conclusion is erroneous. Halifax is suffering from the want of co-operation between the general body of medical practitioners of the town and its medical officer of health, and we trust that the Local Government Board will speedily investigate the matter, and assist the authorities to stamp out the present serious epidemic.

#### Completion of Ziemssen's Cyclopædia.

ZIEMSEN'S Cyclopædia of the Practice of Medicine has been completed during the past few days by the issue of Volume IX. There are now seventeen volumes in all, and during the first three years, an instalment was issued every three months with considerable regularity, but the present and last volume is two years behind date, a fault due, we believe, entirely to the German editors. Messrs. Wood and Co., the American publishers, and Messrs. Sampson Low and Co., agents for the work in this country, are to be congratulated upon the completion of their gigantic enterprise—a work of 14,596 pages deserves such an appellation—and upon keeping faith with the subscribers at a great additional and unexpected outlay to themselves.

#### The Fever at Tandragee, Ireland.

FROM our inquiries as to the truth of paragraphs on this subject which have been going the rounds of the papers, we learn that there has been an outbreak of typhoid in that district, not unprecedentedly violent or unusually fatal, that the Belgian flax which was debited by the newspapers with the responsibility for the outbreak is not believed to have had anything to say to it, but that the cause seems to have been the infection of a well by overflowing sewage. Under the existing inefficiency of the Public Health administration in Ireland, the only surprise should be that such outbreaks of typhoid are not of weekly occurrence.

#### The Approaching Meeting of the Social Science Congress in Dublin.

THE assembly of the Congress is fixed to be held in Dublin in the autumn of the present year, and already steps have been taken to organise the meeting and prepare subjects for discussion. With this object a preliminary meeting was held last week at the palace of the Archbishop of Dublin, and a programme was provisionally agreed to. It will contain—the separate and special consideration of—1, Tenemental dwellings; 2, Relief of the poor; 3, Intemperance; 4, Prostitution.

#### Hospital Saturday.

AT the meeting of delegates to whom the administration of the Hospital Saturday Fund is entrusted, the annual report was read, from which it appears the last collection realised £6,604, £1,398 of which was obtained in the streets. This amount shows an increase of £452 on the preceding year, while the expenses connected with the management of the fund have been reduced one-half, being now 14·73 per cent. of the amount received.

#### Devonshire Hospital, Buxton.

THE annual report of the Devonshire Hospital, Buxton, for 1880, shows that during the year 1,189 in-patients were admitted. Extensive works have interfered a good deal, however, with the working of the hospital, but not to the extent which, at one time, it was feared might be necessary. The financial position of the hospital is not unfavourable, the expenditure having been reduced by the inability to receive the full number of patients; the amount received has likewise been less than in the previous year. The alterations in progress are not expected to interfere to a much greater extent with the regular routine of hospital duties.

THE Hospital Sunday Fund in Liverpool realised on the 9th inst., so far as is at present ascertained, a sum of £2,871, against £2,819 last year.

FOR the enlargement of the County Lunatic Asylum the magistrates of Cornwall have sanctioned the expenditure of £20,000, so as to provide accommodation for 160 additional pauper lunatics.

THE rates of mortality per 1,000 last week in the principal large towns of the United Kingdom were—Portsmouth 13, Leicester 15, Bradford 16, Birmingham, Oldham, and Sheffield, 18, Newcastle-on-Tyne 18, Salford 20, London, Plymouth, Norwich, and Wolverhampton, 21, Hull 22, Brighton 23, Nottingham 23, Liverpool, Manchester, Bristol, and Leeds, 24, Sunderland and Edinburgh 25, Glasgow 26, and Dublin 31.

OF deaths last week from diseases of the zymotic class, scarlet fever showed the largest proportional fatality in Sunderland, Norwich, Nottingham, and Oldham; and whooping-cough in Nottingham, Portsmouth, Sunderland, and Leeds. The highest death-rates from fever (principally enteric) occurred in Plymouth, Leicester, Dublin, and Leeds. Of the 17 deaths referred to diphtheria in the twenty towns, 11 occurred in London. Small-pox caused 38 more deaths within London and its Outer Ring of suburban districts, 2 in Birmingham, and 1 in Dublin, whereas no fatal case was recorded in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE WORLD RESPECTS PEOPLE WHO RESPECT THEMSELVES.—GOVAN-HILL.—Some time ago we referred to the retirement of Dr. Hall, from the position of medical officer of health, to this infantile burgh, and the dignity displayed in so doing. As in other cases, unfortunately too frequently, there are not wanting numbers of people willing to step into any gap, no matter how created. On the 11th inst., a meeting of the Police Commissioners of this burgh was held in the Burgh Chambers. A letter was read from John V. Wallace, Esq., M.D., Langside Road, intimating his acceptance of appointment as medical officer for the burgh, the duties to be as stated, viz., that he should consult with the magistrates and officers of the burgh in all matters requiring

a medical opinion, make examinations, submit reports, and attend courts when required at a salary of £12 per annum ! the engagement to be terminable on a month's notice on either side. The charges, it was agreed, should come out of the burgh funds. Mr. Steele, with reasonable surprise, observed that he could scarcely believe that any medical gentleman would be willing to accept such an amount of work at such a remuneration, and asked if the appointment had been confirmed by the Board of Supervision. Provost Millen pointed out that the appointment was not under the Public Health Act, and therefore the sanction of the Board was not required. We cannot congratulate Dr. Wallace on this appointment ; yet the medical profession is being so beggared by inordinate charitable work, falsely so-called, and the struggle for existence is so pressing, that one can hardly be surprised, if such of its members as are not in possession of private means, are now and then obliged to accept appointments at the income of female domestic servants of the lower type. What will the state of the profession be with a new hospital on the south-side ?

**THE NEW MATERNITY HOSPITAL, GLASGOW.**—On the 11th inst., the New Maternity Hospital, at the corner of North Portland Street and Rotten Row, was formally opened by Lord Provost Ure. Among those present, were Professor Gairdner, Colonel Clark, several Bailies, Drs. Wilson, Scott Orr, &c. It is not said that this institution was opened by prayer. The proceedings were opened by Mr. R. R. Grant, the Deputy Chairman of the Board of Directors, who explained the circumstances which led to the erection of the new building. Not only, he said, was the former hospital "done," but attacks of disease had been frequent in it, and personal attacks, we may add, quite as frequent and more entertaining. On account of the outbreaks of disease it had several times to be closed, to the great dissatisfaction of the public. This seems rather as a revelation to us, as we were always led to believe that "the maternity" was one of the strongholds of the carbolic acid panacea, and that here, at least, disease, and it were incompatible. The new edifice, which was designed by Mr. R. Baldie, architect, was estimated to cost £8,500, but the actual sum would probably be somewhat larger, and, with the exception of about £900, the whole of it had been already provided, £4,132 by public subscription, and £1,700 out of a reserve fund under the control of the directorate. Professor Gairdner, speaking for the medical profession, was sure that on the part of its members nothing would be wanting to keep up the credit of the institution. Now that the directors had passed through their little period of trouble [their gestation] he hoped the public would thoroughly and earnestly support the hospital in such a manner as to make it worthy of the city. The Lord Provost remarked that, having examined the building, he could, with perfect truthfulness, declare it to be in a fit condition to be opened for the purpose to which it was to be devoted. Dr. Scott Orr moved a vote of thanks to the subscribers and building committee.

**GLASGOW DEATH-RATE.**—For the week ending with Saturday, the 9th inst., the death-rate of Glasgow was 26 per 1,000 per annum, as against 23 in the preceding week ; and 23, 28, and 24 in the corresponding weeks of 1880, 1879, and 1878 respectively.

**HEALTH OF EDINBURGH.**—The death-rate of Edinburgh for the week ending with Saturday, the 9th inst., was 25 per 1,000 per annum, the deaths having risen from 81 to 107 ; 19 occurred under one year, and 24 above 60, of which 4 were above 80, and 1 above 90. Chest diseases accounted for fully 50 deaths, and scarlatina for 9. The extreme se-

verity of the weather accounts for the large percentage of deaths from chest affections.

**THE PROPOSED FEVER HOSPITAL AT EDINBURGH.**—A meeting was held on the 10th inst. of the Joint Sub-Committee of the Lord Provost and Public Health Committees in reference to the proposed fever hospital. The propriety of purchasing a portion of the old infirmary buildings for conversion into a hospital for the treatment of infectious diseases was, we believe, fully discussed, and while this plan found influential support, a strong feeling was expressed on the other hand that, if such an hospital were necessary, it should be erected outside the city. Ultimately it was decided to request the medical officer of health to prepare a report on the accommodation at present existing for the treatment of infectious diseases in the city, and to suggest what, in the circumstances, it may seem desirable to do.

**VITAL STATISTICS OF THE PRINCIPAL SCOTCH TOWNS.**—From the registrar-general's returns for the week ending Saturday, January 8, we learn that the death-rate in the eight principal towns was 25·9 per 1,000 of estimated population. This rate is 3·6 above that for the corresponding week of last year, and 3·4 above that for the week immediately preceding. The lowest mortality was recorded in Greenock—viz., 15·9 per 1,000—and the highest in Paisley—viz., 36·0 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 4·1 per 1,000, being an increase of 0·4 on the rate of last week. Acute diseases of the chest caused 161 deaths, being an increase of 20 on the number for last week, which was exactly accounted for by the increase in Glasgow.

**ALLEGED FATAL ASSAULT IN A LUNATIC ASYLUM.**—The Board of Lunacy in Scotland were last week engaged in the investigation of a case of death from fractured ribs in an insane patient, at the Govan Asylum at Merryflatts. The deceased was admitted about two months since suffering from an acute form of mania. He was of a very powerful build, required constant watching, and considerable physical strength to keep him from injuring himself and others. During a violent seizure on the 2nd inst., the two night watchers are supposed to have used more than necessary force to subdue him as on the morning of the 3rd inst. Dr. Liddell, the medical superintendent, found him to be suffering from fractured ribs. Thereupon he communicated the circumstance to headquarters, and the two warders were, after examination, committed on remand.

### NOTIFICATION OF INFECTIOUS DISEASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to state that you have wholly misunderstood the tenor of some of my remarks upon the above subject. If you refer to the report of my observations in the current number of your journal you will see that I have stated that the medical profession are all but unanimous that someone should notify the existence of infectious diseases. You are surely not in earnest in attempting to "negate" this affirmation ? I do not think you could show any evidence to prove that even an important minority of the profession are opposed to the principle of notification. In fact, I do not myself know a single person opposed to it, unless you are yourself prepared to disapprove of notification in any form or by any person, medical or non-medical.

I remain, Sir, your obedient servant,

CHARLES A. CAMERON.

[Neither Dr. Cameron, nor any other of the writers and speakers in favour of compulsory notification of infectious disease, made it clear, in speaking of the approval of the project

by the profession, that that approval had reference to principle and not to the method by which notification was to be effected. On the contrary, they have all left it to be understood that the medical profession approves of compulsory notification as proposed by its advocates in Dublin; and from the statements to which we referred, the daily press has taken up this idea, and has assumed that the proposals of Dr. Cameron are backed up by the voice of the medical practitioners of Dublin. This—so far as the profession has declared its opinion—is not the fact. It has agreed that infectious disease ought to be notified; but there is reason to believe that it does not agree that the physician should be the notifier in writing. This latter is Dr. Cameron's proposition, and it is the enactment of the Bill just introduced by Mr. Gray, the ex-Lord Mayor. It was, therefore, our duty to point out that the public statements of Dr. Cameron conveyed an erroneous impression respecting the attitude of the profession on this subject.—ED. M. P. & C.]

### FISH-EATING AND LEPROSY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to Surgeon-Major Curran's letter on the connection of fish-eating and leprosy, I think I may safely aver that no case has been reported in the south of Ireland during the present century.

The Leper Hospital at Waterford is said by tradition to have been founded by King John, who having either eaten too much unwholesome salmon at Lismore, became afflicted by some serious skin disease, of which he was cured by drinking the water of a well dedicated to St. John, which then existed near the site of the present hospital. I fancy that in those days all bad skin disease was confounded with leprosy.

The worst case of eczema I ever saw was on the face, throat, and chest of a gentleman who ten days before had eaten of a spent salmon taken in the month of November, and there is a strong prejudice which, I think, is well founded, against the use of such fish unless when dried and salted.

When I settled here on the banks of the river, now close on half a century ago, salmon was only 3d. to 4d. a pound, and it was a custom with many families to dry and salt a large number of those fish during the autumn and use them during the winter in various forms of fish pies, and I cannot recall any case of skin disease produced by the use of wet fish. It was the custom in Clonmel and other boroughs to insert clauses in the indentures of apprentices that they should not be fed more than a certain number of days in the week on salmon, an unnecessary precaution at the present day.

I am, Sir, your obedient servant,

Portlaw, co. Waterford,

JAMES MARTIN.

Jan. 2, 1881.

### BICARBONATE OF SODA AS AN EMULSIFIER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I have never heard or seen that soda bicarb. has been used in making an emulsion, I beg to state that I have used it for this purpose, and found it answer admirably.

The following prescription will serve for an example:—

R Sodæ bicarb. grs. xv;

Spts. chloroformi, ʒj;

Aquæ cinnamomi vel menthæ ss., ʒx., solve.

Et adde ol. ricini ʒvj., agita bene ft. haustus.

The advantage of this over other emulsifiers is, that the resulting mixture is thinner, less nauseous, and more readily made, and in using it with copaiba, it serves a double purpose, as it renders the urine alkaline, which, of course, is useful in gonorrhœa, &c.

Once the emulsion is made, any quantity of water may be added without separating the ingredients. The softest water procurable should be used, viz., rain or Vartry.

I remain, yours &c.,

T. W. MORRIS, B.A., &c.

53 High Street, Dublin.

## Literature.

### CONSUMPTION AS A CONTAGIOUS DISEASE. (a)

A TRANSLATION of Professor Cohnheim's pamphlet "Die Tuberkulose vom Standpunkte der Infectious Lehre," forms the first 24 pages of this book. The translator deserves the thanks of the profession for his carefully performed work. The rest of the book is mostly devoted to the continuation of the argument in favour of the contagious character of consumption, and to a few brief and far too general remarks on the extremely complicated disease in question. It would appear that the writer, feeling strongly on the subject of contagion, falls naturally into the error of generalisation, and is rather inclined to ignore any other origin for consumption. He thus expresses himself "The one essential cause is the specific corpuscular contagious virus." We cannot go this length with him, for although recognising as a distinct disease miliary tuberculosis, and also rapid or galloping phthisis, being inclined to regard both these as mayhap contagious in character, we look upon the other varieties of phthisis, that is, the common or sub-acute, as secondary always to an inflammation affecting primarily the vesicular or bronchial tissue of the lungs. We were rather surprised to find that the writer placed so little stress on the condition of lungs hereditarily predisposed to break down rather than to recover from attacks of inflammation. Although glad to testify to the interesting character of the book and to recommend all interested in this disease to read it, we cannot but deplore that any—although scanty—room was found for the hackneyed subject of physical signs and treatment. Had any new material been introduced under these heads, there would have been naturally an excuse for mentioning it. As it is, however, these remarks are of little value. Doubtless interesting to lay readers, but of no use to those of the writer's own profession.

### WILSON'S HEALTH RESORTS. (a)

In a handy and attractive little volume Dr. Wilson has brought together a considerable amount of information suitable for invalids in search of places likely to help in restoring them to health. In a preliminary chapter on "Health and Disease," Dr. Wilson dwells on the importance of "change" as a therapeutic agent, and while he draws a scarcely flattering picture of the resources of medicine, few will dissent from his conclusions respecting this subject. It is possible, however, that all will not follow him in his dissertation on pulmonary consumption, although there is sound treatment in most of the advice he tenders. The descriptions of the health resorts are terse, sufficient, and clear, and serve the purpose they are intended to fulfil, by indicating for whom, that is, what class of invalids should proceed to each in search of relief to their symptoms. The concluding section of the work, on mineral springs, is an excellent guide to the features of the most important situations in which these natural fountains occur, and the whole work will prove an useful and acceptable companion to the sick and ailing of all places.

### ANOTHER NURSING DIFFICULTY.

WITH reference to the remarks made under the above heading in our last issue, we are assured by Dr. Palfrey that the information conveyed to us is certainly incorrect so far as it concerns the London Hospital. The lady superintendent, Miss Lückas, has not introduced any change whatever into the nursing system of that institution, and the relations existing between that lady and the staff of the hospital are of the most cordial and friendly character.

(a) "Health and Health Resorts." By John Wilson, M.D. Trubner and Co.

### INTERNATIONAL MEDICAL CONGRESS, (LONDON, AUGUST 2ND TO 9TH, 1881.)

The following programme in the Section of Medicine has just been decided on—*President*: Sir William Withey Gull, Bart., D.C.L., LL.D., F.R.S. *Vice-Presidents*: Professor W. T. Gairdner, Dr. George Johnson, F.R.S., Dr. Richard Quain, F.R.S., Dr. William Roberts, F.R.S. *Secretaries*: Dr. Dyce Duckworth, Dr. William M. Ord. *Lists of Subjects for Discussion*.—1. Localisation of Disease in Brain and Spinal Cord, so far as pathognomonic and diagnostic. 2. Trophic changes of nerve-origin. 3. Vascular changes, functional and organic, in Disease. 4. Primary diseases of the Lymph-system. 5. Gout, Rheumatoid Arthritis, and Rheumatism. 6. Forms of Renal Diseases (Bright's Diseases). 7. Methods of Physical Diagnosis. 8. Therapeutic Methods:—Revsulsions, Blood-letting, Diet-cure, Uses of Heat and Cold, Drug-cure, &c.

All communications regarding Section 4 should be addressed to Dr. Ord, 7 Brook Street, Grosvenor Square, London, W.

**Odontological Society of Great Britain.**—At the annual general meeting held 10th January, the following members were elected as officers and councillors for the year 1881. *President*: Mr. Thomas Arnold Rogers. *Vice-President*: Messrs. Joseph Walker, J. Smith Turner, Charles S. Tomes, Alfred O'Meara, J. E. Rose, Samuel Lee Rymer. *Treasurer*: Mr. James Parkinson. *Librarian*: Mr. Felix Weiss. *Curator*: Mr. S. J. Hutchinson. *Honorary Secretaries*: Mr. J. Howard Mummery (for Foreign Correspondence), F. Canton (Council), Mr. T. F. Ken Underwood (Society). *Councillors*: Messrs. J. Oakley Coles, W. H. Woodhouse, Edwin Saunders, T. Chartres White, G. Wallis, W. F. Henry, Alfred Coleman, H. Moon, J. Stocken, W. A. Hunt (Yeovil), T. W. G. Palmer (Cheltenham), T. J. Browne-Mason (Exeter), W. Williamson (Aberdeen), J. E. Palmer (Peterboro'), William Fothergill (Darlington).

### NOTICES TO CORRESPONDENTS.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**"CLINICAL LECTURES ON INFANTILE PARALYSIS."**—We propose commencing some valuable lectures on this subject by Dr. Buzzard in our next issue.

**BROMPTON CONSUMPTION HOSPITAL.**—A course of "Clinical Demonstrations of Cases of the less common Diseases of the Chest" will be commenced this (Wednesday) afternoon at 3 o'clock by Dr. J. Mitchell Bruce.

**"THE BLUES."**—In connection with the annotation on this subject in our last number, a correspondent who suffers occasionally from himself says, the remedy he always takes, and, moreover, prescribes with good effect, is coca in doses of ℥ss. of the fluid extract.

**AN INQUIRER.**—We have no personal experience of "Hazeline," it is under trial at the present moment; we will report results in due course.

**STUDENS.**—You should get Harris and Power's "Manual for the Physiological Laboratory," it is the most practical little manual on the subject we have had the pleasure of examining.

**THE QUALITIES OF A GOOD SURGEON.**—In the year 1863 Guy de Chauliac wrote in the introduction to his work on Surgery as follows: "The surgeon should be learned, skilled, ingenious, and of good morals; be bold in things sure, cautious in dangers; avoid evil cures and practices; be gracious to the sick, obliging to one's colleagues, wise in his predictions; be chaste, sober, pitiful, and merciful; not covetous nor extortionate of money, but the recompense be moderate according to the work, the means of the sick, the character of the issue or event and its dignity." What sounder advice can be now offered five centuries later.

**ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.**—Wednesday, Jan. 26, at 8.30 p.m., Annual General Meeting.—*Agenda*: Mr. W. A. N. Catlin, F.R.C.S., "On the Imperfections of the Dentist's Act, with suggestions as to the alterations required to protect the Interests of Qualified Surgeons."

### VACANCIES.

**Ballinrobe Dispensary.**—Medical Officer. Salary, £125. Election, Feb. 10.  
**Dromore Dispensary.**—Medical Officer. Salary, £115. Election, Jan. 20.  
**Glasgow Faculty of Physicians and Surgeons.**—Faculty Lectureship. Full particulars on application to the Secretary.  
**Liverpool Dispensaries.**—Assistant House Surgeon. Salary, £108. Applications to the Secretary before Jan. 24.  
**Maguirebridge Dispensary.**—Medical Officer. Salary, £115. Election, Jan. 24.  
**Manchester Hospital for Sick Children, Pendlebury.** Junior Resident Surgeon. Salary, £80, with board. Applications to the Chairman before Jan. 27.  
**Queen Charlotte's Lying-in Hospital, London.**—Resident Medical Officer and a Medical Officer for Out-patients. Salary for the former office, £80, with board; the latter, honorary. Applications to the Secretary before Jan. 25.  
**Richhill Dispensary.**—Medical Officer. Salary, £140. Election, Jan. 21.  
**Royal Free Hospital, London.**—Junior Resident Medical Officer. Board provided, but no salary. Applications to the Secretary before Jan. 26. (See Advt.)

### APPOINTMENTS.

**EVANS, E. P., L.R.C.P. Ed.,** Medical Officer for the Mountain Ash District of the Pontypridd Union.  
**HASLAM, G. J., M.D., M.B.C.S.E.,** District Surgeon to the Salford and Pendleton Royal Hospital.  
**HEMANS, G. E., M.B., M.R.C.P.L., F.R.C.S.E.,** Physician to the Eastern Division of the Royal Maternity Charity, London.  
**ILLINGWORTH, C. R., M.B., C.M.,** Medical Officer for the Rishton and Clayton-le-Moors Districts of the Blackburn Union.  
**LEAHY, A. W. D., M.R.C.S.,** Medical Registrar at Charing Cross Hospital.  
**MAHON, G. A. D., M.B.C.S.E.,** Medical Officer for the Eighth District of the Newport Pagnell Union.  
**MILNES, G. H., M.R.C.S.E.,** Assistant House Physician to St. George's Hospital.  
**NEWTON, J., M.R.C.S.E.,** House Surgeon to the Salford and Pendleton Royal Hospital.  
**SMITH, R. M. D., C.M., M.R.C.P.L.,** an Assistant Physician to Charing Cross Hospital.

### Births.

**ELLISON.**—Jan. 13, at Blythe House, Forest Hill, the wife of Frederick W. Ellison, M.R.C.S., of a son.  
**GIVEN.**—Jan. 7, at Gortin, co. Tyrone, the wife of George K. Given, M.D., of a son.  
**HEMSTED.**—Jan. 12, at Freemantle, Southampton, the wife of Edwin Hemsted, M.D., of a daughter.  
**M'BRIDE.**—Jan. 14, at Glenview, Freshford, the wife of A. M'Brade, M.D., Fleet Surgeon, R.N., of a son.  
**RICE.**—Jan. 13, at Swift's Hospital, the wife of William Rice, F.R.C.S., of a son.  
**SHELDON.**—Jan. 14, at 123 Cornwall Road, London, W., the wife of Thomas Sheldon, M.D., of a son.  
**THOMPSON.**—Jan. 8, at The Lawn, Belturbet, the wife of H. W. Thompson, M.D., of a daughter.  
**TICHBURST.**—Jan. 8, at Stichester House, St. Leonard's-on-Sea, the wife of A. E. Tichehurst, M.R.C.S., of a son.

### Deaths.

**ALCOCK.**—Dec. 23, at Catherine Street, Waterford, Daniel R. Alcock, Staff Surgeon, R.N. (retired), aged 43.  
**BAIR.**—Jan. 8, at Bournemouth, Benjamin Bain, L.R.C.S. Ed., late of Birtley, co. Durham, aged 87.  
**COOPER.**—Jan. 8, at 79 South Hill Park, Hampstead, Thomas Henry Cooper, M.R.C.S., aged 38.  
**DOWNING.**—Jan. 7, at Franklin Road, Brighton, Edward H. Downing, M.R.C.S.E., of Deptford, aged 51.  
**ROBERTS.**—Jan. 13, at 78 Southwark Bridge Road, London, Ellen, the wife of John D. Roberts, M.R.C.S.E. (formerly of St. Anstall), of bronchitis, aged 40.  
**TIMS.**—Jan. 8, at North Street, Langport, Thos. L. Tims, L.R.C.P. Ed., M.R.C.S.  
**WOOLLERY.**—Dec. 31, at Kent Cottage, Old Kent Road, S.E., S. Poole Woolley, M.D., M.R.C.S., aged 56.  
**WHITE.**—Dec. 29, at Duncan Terrace, Newington, Edinburgh, William Alexander White, M.D., F.R.C.S.E., Deputy Surgeon-General (retired), A.M.D.  
**WHITE.**—Jan. 2, at Clifton, Bristol, Charles Whyte, Inspector-General of Army Hospitals, aged 85.

## CLINICAL LECTURES

ON

### INFANTILE PARALYSIS, AND ACUTE ANTERIOR POLIO-MYELITIS IN ADULTS. (a)

By THOMAS BUZZARD, M.D., F.R.C.P.,  
Physician to the Hospital for the Paralyzed and Epileptic.

#### LECTURE I.

I PROPOSE in my lecture to-day to bring under your notice some cases of acute atrophic paralysis occurring in children. Up to a comparatively recent period the disease, of which you will see some examples, was called "infantile paralysis," or "essential paralysis of children," in consequence of its being supposed to be peculiar to that time of life. Later observations have, however, shown that it is by no means infrequent in adults, although probably occurring in much less proportion in them than in children, and especially in infants under two years of age.

Pathological investigations have shown that the disease is an acute form of systematic myelitis affecting the anterior portion of the grey matter of the spinal cord, and hence the name *polio-myelitis anterior acuta* (πολιός, grey; μωλος, marrow; ιτις, inflammation). The term systematic myelitis has been applied by M. Vulpian for inflammation which is restricted to certain systems of fibres or cells in place of being diffused over various parts of the section of the cord indefinitely. It is especially to the work of M. Charcot that we owe our knowledge of the existence of these systems of fibres. The accompanying scheme, which is very slightly modified from one given by Dr. Grasset, of Montpellier, in his admirable "Maladies du Système Nerveux," will be found useful in showing the position of acute anterior polio-myelitis among the other forms of systematic myelitis. It is indicated in italics.

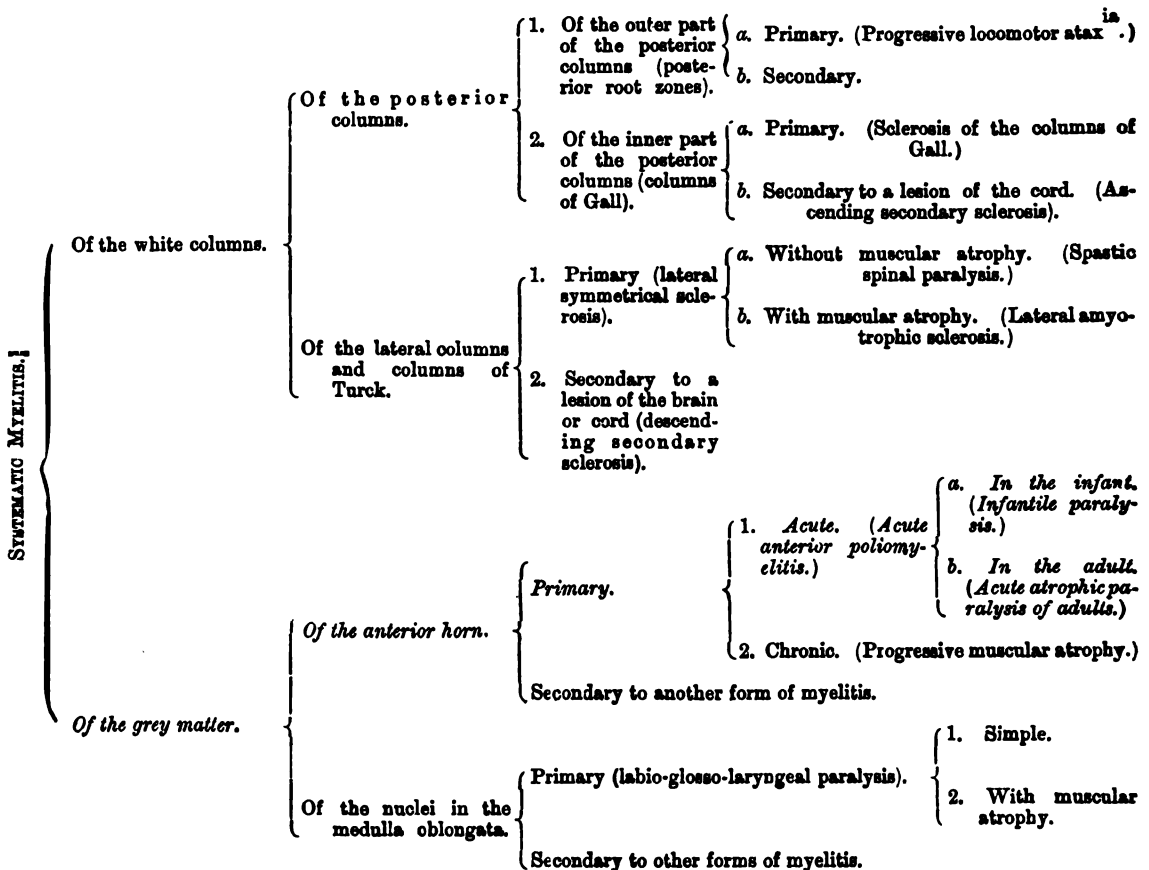

It should be remembered that, although a scheme of

this kind indicates in a general and convenient fashion the names applied to disease attacking various systems of fibres or cells in the cord, it must not be taken to be strictly accurate in detail. The pathological changes are not often confined absolutely to the localities indicated, although in these they may certainly be expected to be most strongly marked.

Before presenting to you some examples of acute atrophic paralysis which are at present under my care, I will give you a sketch of the symptoms of the disease.

As it occurs in infancy (and it is peculiarly apt to attack children under two years of age) the essence of the disease is this, that after a varying amount of febrile movement, one or more, or all, of the limbs are observed to be paralysed. You cannot always obtain a history of fever in these cases, but experience seems to show that absence of a certain amount of febrile disturbance is at all events exceptional. In a case lately in the hospital, and now attending as an out-patient, Mr. Broster, our then resident medical officer, made the following note of the mode of onset: "A strong healthy child when six months old used to pull herself up from the floor and walk by aid of the furniture. When she was fifteen months old her mother, who had to go out to work, left her in the morning quite well. When she returned at night the child seemed feverish and fretful. She was poorly for several days, and her mother kept her in bed. After this she got up again, but now she did not attempt to walk or climb upon chairs as she had previously done, and her mother noticed that the right leg felt quite soft and seemed quite useless." In other cases the febrile movement is much more marked, and excites suspicion of the onset of some zymotic disorder. In others, again, the first symptom to attract attention is the loss of power. In a case which I saw a few days since, a child, 11 years of age, had romped with other children in the afternoon and sat up to her parents' dessert. She went to bed and only woke once. Her bed companion noticed that she got out of bed and appeared to have some difficulty in getting in again. She was not feverish. Next morning she could not stand nor raise her body in bed.

(a) Delivered at the National Hospital for the Paralyzed and Epileptic.

There is a curious difference in the duration of the febrile disturbance. Duchenne fils found, in examining records of seventy cases, periods of fever lasting from one hour to fifteen days. The duration and intensity of the fever were thought to be, as a rule, less long the younger the child. The paralysis most often occurs with great rapidity, but occasionally, although rarely there is a gradual loss of power dating from the initial fever. The disease sometimes occurs at the close of a specific fever—as typhoid. I have seen it follow measles.

Out of sixty-two cases, Duchenne fils noted five in which the paralysis was general; nine, paraplegia; one, hemiplegia; two, crossed paralysis (the right upper and left lower limb); twenty-five in which the right lower limb was affected; seven of the left lower limb; ten of the right or left upper limb; two, lateral paralysis of the upper limb; and one case in which the muscles of the trunk and abdomen were paralysed. My own observation would lead me to think that the muscles of the trunk are not unfrequently involved.

Dr. B. Lees exhibited not long since, at the Clinical Society, two cases in which the serrati magni had remained paralysed after an attack of infantile paralysis. Occasionally, though I think very exceptionally, there is paralysis of muscles supplied by the medulla oblongata. I shall be able to show you in the next lecture an example of the kind.

In addition to the fever there may have been convulsion, coma, some transient loss of cutaneous sensibility, and a temporary trouble with the bladder or rectum, but to a great extent (though not exclusively) the brunt of the disease falls suddenly, or at least very rapidly, upon the motor power of a limb or limbs. Now and then there are pains in the limbs, with tenderness to the touch. There is no tendency to formation of bed-sores in typical cases. After the first day or so, any change which takes place in

the power of movement is a change for the better. The limbs do not become more paralysed. On the contrary, after a few weeks, or sometimes days, there is a gradual clearing off of the difficulty as regards some of the limbs, one or more perhaps remaining unimproved. Or the paralysis may remain limited to a few muscles in one limb. There are rarely or never relapses, so that the return of power in a limb may be regarded with confidence as of permanent, and not temporary, character.

Let me now draw your attention to the most remarkable feature in this form of paralysis. Many of the muscles paralysed lose their faradaic excitability entirely within a week, and rapidly waste. But although they fail to respond to the strongest induced currents they react to slow interruptions of the constant current (reaction of degeneration). The nerves to the muscles, on the other hand, lose their excitability to both forms of electrical excitation. Some, again, of the muscles whose faradaic excitability has been lowered, but not lost, are not long in regaining the power of contraction to voluntary impulses. This rapid loss of faradaic excitability is peculiar to the disease. In no other form of more or less generalised paralysis (unaccompanied by marked sensory disturbance) do you find within a few days that the muscles fail to contract to induced currents.

The earliest opportunity which Duchenne had of examining into the electrical condition of the muscles in a case of this kind was the third day. In that instance the right arm was paralysed. It was not until the fifth day that the electrical excitability of the deltoid was notably enfeebled. On the seventh day, however, it was completely abolished. His experience was, that if the muscles have retained, after the seventh or eighth day, some amount of electric contractility they always recover their motility, and the more rapidly the less the excitability has been enfeebled,

F. Müller has found the excitability of the nerves lost on the fourth day, and that of the muscles on the fifth and sixth days. The muscles paralysed are flaccid. The reflex from the sole of the foot is usually absent in cases of paralysis of the lower limb, and so also is the patellar tendon reflex where the muscles on the front of the thigh are involved.

The second period of the disease begins a few weeks, or may be delayed for several months, after the attack. It is called the period of regression, for in it there is a gradual return of power in more or less of the muscles, and their excitability to faradism again appears. The amount of recovery differs extraordinarily in cases, so that it is impossible to say more than this that when several limbs are attacked at first it is much more common than not for some of them to recover, but rare for all to do so. The mode in which recovery takes place is also very uncertain, in some muscles proceeding rapidly, in others very slowly. It occasionally happens that muscles which have remained for some time irresponsive to electrical stimuli (either induced or slowly interrupted voltaic currents) will suddenly show reaction to the latter, and increasing amendment follow. More often than not, perhaps, where the paralysis is extensively distributed, the improvement in the upper extremities precedes that which takes place in the lower limbs. With return of voluntary power and faradaic excitability, the muscles which have wasted gradually regain their volume. Those which remain paralysed, on the contrary, take no part in this amendment, but are more and more marked out by contrast with the others. I have found great differences in regard to the excitability by electrical currents in the muscles. In some cases muscles have refused to show response to either form of current after a few months, in others even after several years, though the limb continued helpless the application of a slowly interrupted voltaic current would bring about a distinct though feeble contraction. Voluntary power usually returns long before Faradaic excitability.

In the sequel of the disease atrophic changes are marked in the muscles, which may be so wasted as to leave the limb in a skeleton-like state, or fatty substitution may mask the real loss of muscular substance, and give a false air of plumpness to the limb. The development of the osseous system is more or less arrested, so that a bone may, in course of years, be some inches shorter, and considerably thinner than its fellow. There is diminution in the calibre of blood-vessels leading to comparative coldness and blueness of the limb, which also often shows unusual liability to chilblains. And most important of all, perhaps, the tonic of such muscles as remain sound or comparatively little injured causes them gradually to overpower those whose function is destroyed giving rise to deformities which often tend to persist and increase in spite of all efforts to reduce them. In this manner are produced the greatest number of those forms of club-foot which are not congenital. The relaxed state of the ligaments of the joints in these cases is a noteworthy and characteristic sign of the disease, the shrunk and useless member hanging like a flail. At a comparatively early period of the disease there will often be found a tendency to deformity, though at that time reduction by the hand (which later becomes impossible) is not difficult.

Duchenne says (*a*) that, by electric exploration, he has always found a greater quantity of healthy fibres in the contracted or retracted muscles than in the others. And this is what might be expected. In the commencement all the muscles of the limb affected are paralysed; later on certain muscles recover their contractility after having been more or less atrophied, and these draw the limb in their direction when their contractility appears. Their continued shortening determines, in the end, their retraction, the shortening of certain ligaments, the deformity of limbs and articular surfaces. Other muscles remain paralysed, and very probably undergo textural changes. It is in the antagonists of the retracted muscles that the

greatest fatty changes are found, but not exclusively in them.

I show you a boy who was attacked five months ago with this disease, and notes of whose case have been taken by Dr. Beevor, Resident Medical Officer.

CASE I.—Ernest R., *æt.* 4, the youngest of ten children, of whom two died at birth, was admitted into the hospital on October 6, 1880, on account of loss of power in the right leg. It seemed that three months previously to his admission, the child had a febrile attack which lasted a few days, and on its recovery from this it was observed that it could do nothing with its right leg. The other limbs appear from the history to have been unaffected. Since then it had slightly improved. When admitted, the child could not stand, and could only crawl upon the ground. It could not extend the knee or flex the hip-joint or move the ankle. The right leg was rather smaller than the left.

The boy has improved, as you see, since he came here. He can now stand and walk, although imperfectly. The knee-joint is lax, the internal lateral ligament being weak, and perhaps still more the capsular fibres (forming a lateral ligament) which are prolonged downwards from the insertion of the vastus internus to the inner tuberosity of the tibia. The leg, therefore, forms an obtuse angle with the thigh, the apex inwards. When seated he cannot extend or flex the leg, or lift the knee or the foot. Standing he can lift the foot off the ground by the iliaco-psoas.

Let me call your attention to certain points in the paralysed limb. In the first place there is no loss of cutaneous sensibility in it. He feels touches and pinches just as well with this leg as with the other, and this has been the case throughout. When he takes a warm bath the water feels just as warm to one leg as the other. He is too young for the muscular sensibility to be tested.

Next, the limb is distinctly smaller than the corresponding one, and Dr. Beevor who has, at my request, examined into this point, informs me that the diminution in size can be traced especially to the quadriceps (especially the vastus internus), the anterior tibial group, and the peronei, as well as, though to a less extent, to the calf muscles. You will note here, therefore, and this is a point to be remembered, that we have not to do with an affection of muscles, all of which are in the district of one particular nerve, or even of a single plexus of nerves. The quadriceps femoris, you will remember, is supplied (along with most of the other muscles in the front of the thigh and the iliacus) by the anterior crural nerve, which arises mainly from the third and fourth lumbar nerves. The anterior tibial muscles and peronei, on the other hand, derive their nerve supply from the great sciatic, which arises from the lumbo-sacral cord and the four upper sacral nerves. But so also do the muscles of the calf, which are not so much affected as those in front of the leg. A measurement made on November 9 gave the following: Right calf,  $7\frac{1}{4}$  inches; the left,  $8\frac{1}{2}$ . Right thigh (3 inches above patella), 10; the left,  $11\frac{1}{4}$  inches.

The patellar tendon reflex, you will observe, is absent on the right side, present on the left. Tickling the sole of the right foot causes a very slight reflex contraction of the muscles. On the left side the contractions are vigorous. There is no loss of cutaneous sensibility. The muscles of the right limb when last examined did not react to faradism, but contracted to slow interruptions of a constant current from ten cells of a Stöhrer's battery.

If one rheophore from an induced current machine be applied to this child's back and the other placed in succession over the motor points of the muscles of the thigh and leg no contraction is produced by a stronger current than is amply sufficient to cause vivid contractions of the corresponding muscles of the left limb. In order to save the child from pain as much as possible the current is interrupted slowly by pressing the hammer of the machine, instead of allowing this to be done rapidly by the automatic arrangement for the purpose. By degrees a very

(a) "L'Electrisation Localisée." Third Edition. Page 412.

powerful current can thus be put on, yet no contraction is caused.

If now there be substituted for faradaism the constant current derived from a voltaic battery, one rheophore being placed on each muscle in turn (the other being on some indifferent spot), it is found that when the current is gradually strengthened till it comes from ten cells, and this is interrupted by using a commutator, contraction takes place in the paralysed muscle.

I may say that, on October 6, when the boy was admitted it required a current coming from twenty cells to produce contractions.

On November 9, a month later, ten cells were sufficient. Throughout there has been no response at all to any strength of faradaic currents.

This is an example of a very common form of infantile paralysis. Before showing others, I should like to say a few words upon the pathological anatomy of such cases.

*To be concluded.)*

### PARTIAL EXCISION OF THE TONGUE. (a)

By WILLIAM THOMSON, F.R.C.S.,

Surgeon to the Richmond Hospital, Dublin; Member of the Court of Examiners, R.C.S.I.; and Examiner in Surgery, Queen's University, Ireland.

I wish to bring before the Society two cases in which I have performed partial excision of the tongue; and to raise two or three questions regarding the surgical methods of treating some diseases of that organ.

The first was that of a woman, aged about 50, who had suffered from an ulcer of the right side of the tongue for some months before she came under observation. When she presented herself the ulcer had all the appearance which indicate epithelioma. The induration extended across the median line, and corresponded to about the middle third of the tongue, from before backwards. The discharge was fetid, the pain was of the usual darting character; and as there were no enlarged glands discoverable, it was deemed a case in which the relief of an operation might be given. Accordingly, I proceeded to remove the anterior portion of the tongue with the *écraseur*. As the disease was further back than could be reached through the mouth, I adopted Colles's plan of slitting the cheek from the anterior edge of the masseter to the labial commissure. This gave very ample room, and when the *frænum* had been freely divided, I was able to pull the tongue well forwards, and put the chain of the *écraseur* behind the seat of disease. The tongue was transfixed by a stout handled-needle, in front of the loop, so as to prevent that from slipping forward when it was tightened. The screw was turned every half minute, and after a very tedious wait the diseased structure was removed. There was no hæmorrhage; the wound in the cheek was brought together, and the woman was well in about a fortnight. Three months afterwards she again presented herself, with a mass of glands in the sub-maxillary region, and the skin over them ulcerated in one spot. I could not unhappily propose any other operative interference; and the poor woman soon afterwards died.

The second case was that of a man, *æt.* 58, who was admitted to hospital under my care in March, 1878. He complained of a curious filiform-looking growth which occupies the middle of the left side of his tongue. It was about an inch in length from before backwards, extended to within a third of an inch of the central line of the dorsum, and lapped round the edge of the tongue to its inferior surface. The hair-like growths were pale in colour, and some of them were long enough to lie on the

surface of the tongue. He suffered from pains radiating from the angle of the jaw upwards to the temple, and downwards along the side of the neck. There was no glandular enlargement, but the patch was spreading, and the pain was always increased on eating. Three years before, after drinking and smoking to excess he observed three small blisters on the tongue, and came to hospital, where two got well; but the third remained, became warty, and finally assumed the proportions and appearances now presented. He had been under other care for this growth: it had been cauterised without good result; and he now came again under my observation. The growth was regarded as a decidedly suspicious one, and although its malignancy could not be declared, it was thought, looking at the history of the case, and the probability of its becoming cancerous, the best treatment was its immediate removal.

I was not satisfied with the *écraseur* as an instrument for removing growths about the tongue, and I determined in this case to use as the thermo-cautère. The cheek was slit as in the previous case; the tongue was well drawn forwards by a ligature through its tip, and the hot knife applied. The effect was most satisfactory. The tissues were cut through with the greatest ease, the small vessels being sealed up, and when in a couple of minutes the diseased piece had been removed there remained a seared surface, with two vessels in the centre bleeding rather freely. These were ligatured; the edges of the cheek-wound were brought together, and the patient was sent to bed.

There was a slight increase of temperature; and a good deal of pain, always referred to the site of one ligature; but the patient progressed rapidly. The wound in the cheek was entirely healed on the eighth day, and the man was allowed to leave bed. On the ninth day, while drinking some tea, and chatting with other patients, he had a fierce attack of secondary hæmorrhage. My resident pupil, Mr. White, happened to be present, and at once rendered help; but a good deal of blood was lost before the bleeding could be restrained by pressure. There was no more trouble, however, and the patient was quite well in a week afterwards.

I have sections of the growth here for exhibition. They were prepared by Mr. Richardson, and both he and Professor Bennett agree in the opinion that the disease was a papilloma. The patient came to hospital two months ago to show himself. He has remained perfectly well since the operation; the gap in his tongue has greatly diminished; the mark of the incision in the cheek is very slight, and his utterance is clear and distinct.

In speaking of this case a few minutes ago I expressed my dissatisfaction with the *écraseur* as an instrument for the removal of the tongue, and this feeling is based not upon any one case only, but upon others in which I have seen it used. There is no doubt that it will cut through the tissues if you give it time, and that it does so with little loss of blood. But the supposed bloodlessness of the operation is not sufficient to counterbalance the drawbacks; and that is its only positive claim. It is miserably slow in operation; it does not protect infallibly from hæmorrhage, immediate or remote; and if it should turn out that we have cut through a diseased nodule in the centre of apparently healthy tissue, we have to go over the whole process again, or revert to the knife or the cautery. There are cases in which the *écraseur* is a most valuable instrument, but in those of tongue extirpation it has nothing specially to commend its use.

Of the ligature there is little to be said, and certainly nothing favourable. To strangulate a diseased portion of tongue and to allow it to slough off in the patient's mouth is not high surgery; and to entail upon him for several days the presence there of a fetid rotting lump is a quite unnecessary infliction.

The two methods which I think are best suited to the removal of the tongue, or of any part of it, are the cautery and cutting. There are many surgeons who prefer the latter, and I think it presents some advantages. But

(a) Read before the Surgical Society of Ireland.

the hæmorrhage which is likely to follow any extensive removal is a great objection when compared with the other plan. It is not, however, so great as to be deterrent; and we always have the advantage of being able to examine tissues uncharred and unbruised, and so easily determine the character of the divided surface.

The cantery, whether the galvanic or that known as the thermo-cautère, is, I think, the most attractive and the most efficient instrument for operating. I prefer the thermo-cautère because it is less expensive, and more reliable in its action, the method is rapid, its track is almost bloodless, and it can be re-applied at once if we find that sufficient of the diseased parts have not been taken away. This is important, for it is worse than useless to operate if we do not remove all the visibly infected portions. To be on the borderland even only helps by irritation to give increased energy to the disease and make it spread more rapidly.

It is said that this method is liable to be followed by secondary hæmorrhage. Of course a cautery cannot be expected to seal up large vessels; and such arteries as the lingual must be ligatured. But that it is more likely to have the unfortunate complication of secondary hæmorrhage is by no means proved. All plans alike run this risk—the ligature, acupressure, and even the écraseur; so that in this respect, at all events, the cantery is in no worse a position than its competitors.

It is for the reasons I have assigned that I think this instrument most suitable for the removal of parts from very vascular situations, to which in addition access is difficult.

There is still a point, and it is the most important one, to which I should like to direct attention, and that is, as to the extent to which our excision should go in these cases. There is no more distressing disease in some respects than cancer of the tongue, and the surgeon is naturally anxious to give as much relief as possible from its horrors. Unhappily, as we know, the respite is usually short, the disease spreads in the stump and in the adjacent glands, and the patient dies. But still there seems to be no doubt that life is prolonged if the plan adopted be a sound one.

Mr. Fairlie Clark collected notes of thirty-nine cases, and observes, that of these "the average duration was fifty-seven weeks; the shortest ran its course in fourteen weeks; the longest extended over six years. If we divide these thirty-nine cases into two classes—1st. Those which were not operated on, twenty-five in number; 2nd, those which were fourteen in number—we find that the average duration of life after the disease was noticed was, in the 1st class, forty-two weeks, the longest period being less than two years; while in the second class the average was eighty-six weeks, the longest period being six years. Thus, it is evident that the balance is much in favour of the cases that were submitted to operation; and this tallies with the conclusions that have been arrived at by Sir James Paget."

The disease, however, is probably the most fatal of all forms of malignant infection, and if operative means hold out the hope of prolonged life, we should be sure that these means are the best. Now, I am very strongly of opinion that in these cases our operations should be more thorough than they are, and that we should not rest satisfied with the mere cutting out of what is tangibly diseased.

Far beyond the indurated piece of tongue the tissues are almost certain to have already in them the seeds of fresh outbreaks of disease; and there is, therefore, always a danger that in contenting ourselves with a moderate margin of apparently healthy structures we are leaving plenty of trouble behind us. We do not hope that we can remove the disease, but if we are only radical enough in our operation we shall certainly be the means of prolonging life to a greater extent than by mere partial excisions.

Where one side of the tongue only is affected, I should adopt the plan of Mr. Buchanan, of Glasgow, or of Mr. Mount Baker, of London, who, with some differences in detail, split the organ back to its root along the septum,

and then remove the diseased half. The lines of lymphatics are more numerous in the long axis, and the great dangers of infection lie along there. Therefore, where there is good evidence of lateral limitation, such a procedure holds out good hope of success. But when the central line is closely approached or crossed, I submit that the safest and wisest operation is to remove the tongue altogether. I mean by this a free separation of the tongue from the floor of the mouth, and the removal of all of it that is then possible. The operation is not often a fatal one; power of speech is preserved to a very remarkable extent, and the relief from local symptoms and the prolonged life certainly justify it.

## DISEASES OF THE HEART IN CHILDREN.

By W. H. DAY, M.D., M.R.C.P. Lond.;  
Physician to the Samaritan Hospital for Women and Children.

(Continued from page 47.)

### VALVULAR DISEASES OF THE HEART.

*Disease of the Left Auriculo-ventricular Orifice (Obstructive Disease), causing Contraction of the Orifice (Mitral Stenosis) and Obstruction to the Blood-flow into the Ventricle.*—In this disease, congestion of the lungs, hæmoptysis, or pulmonary hæmorrhage may ensue. The effects on the circulation are much the same as in the former case. Chronic bronchitis, pneumonia, and urgent dyspnoea, general venous congestion, and anasarca must be looked for. After a time the embarrassed pulmonary circulation affects the right side of the heart, and its cavities become enlarged; there is increased dulness to the right side of the sternum, and the right ventricle may be seen and felt between the ensiform cartilage, and the receding ribs of the left hypochondrium in long standing cases.

Some cases of mitral constriction are supposed to be of congenital origin, and they continue for years without causing any sign of heart mischief.

The pathognomonic physical sign of obstructive disease of the mitral valve is a presystolic murmur (*auricular systolic*), and when once heard there can exist no doubt as to its significance. The murmur is produced as the current of blood in its natural passage through the heart encounters resistance at the contracted valvular orifice; the valves being converted into a curtain with a slit in it (*the button-hole mitral*), or into a finger-like cone projecting into the ventricle. The bruit immediately precedes the first sound of the heart and carotid pulse; it is presystolic in character, and is coincident in time with the contraction of the auricles, and not that of the ventricles. It would serve no practical purpose to enter into the vexed question concerning the exact time during the heart's revolutions at which this murmur is produced, but I would just notice a remark by Dr. Andrew to the effect that it occurs at the latter part of the diastole and seems to be continuous with the first sound from which it is difficult to distinguish an interval. (a) It is a short and rough murmur, and obliterates the second sound at the apex, but intensifies it at the base. Accentuation of the pulmonary second sound is one of the most constant conditions of mitral stenosis. Its loudness, like all other cardiac murmurs, depends upon the condition of the blood, and the size of the aperture, and the force of the heart's action; but why it should disappear from time to time whilst the constriction remains unaltered is at present unexplained. A cardiac thrill (*diastolic*) is usually present, and the left ventricle is contracted, and its walls thin according to Niemeyer, (b) but Dr. Balfour remarks, "as we never have mitral stenosis without regurgitation, some degrees of hypertrophy of the left ventricle is almost always present, &c." (c) The left auricle is dilated

(a) "On Presystolic Murmurs at the Heart's Apex," St. Barts. Hosp. Report. Vol. xiii. Page 1.

(b) "Practical Medicine," 1875. Vol. 1. Page 363.

(c) "Diseases of the Heart," 1876. Page 153.

and hypertrophied, and the right side of the heart also. The pulse is occasionally regular, but often weak, rapid, and irregular. Mitral obstruction and regurgitation may exist together. (a) The murmur of mitral stenosis is heard at the left apex, and inclining towards the right apex; whilst a regurgitant murmur is carried towards the axilla, or behind from the left nipple to the mesial line at the back. It is heard over a less area than that of regurgitation. It is generally, but certainly not invariably, limited to the mitral area—"that is, within a circle of about an inch, described round the point where the apex impinges as a centre." (b) An attack of pulmonary catarrh with elevation of temperature will often render the murmur softer and more diffused.

The causes which induce valvular diseases of the heart in children are acute rheumatism, chronic albuminuria, chorea, and the specific fevers, especially scarlet fever; indeed, any circumstance which will set up pericarditis and endocarditis may lead to dilatation or contraction of the cardiac orifices, and to adhesion and rigidity of the valves which guard them. Dr. Hayden considers the poison of scarlet fever as next in frequency to that of rheumatism in producing heart disease. "Many of the most formidable examples of valvular lesion that I have met with owed their origin to scarlatina. The patients are generally children, and rarely survive the second period of life. The complication is usually declared in the second week of the fever, but occasionally in the first week, or the stage of desquamation." (c) Endocarditis is set up as we have already seen (*vide* Endocarditis) and the valves, more especially the mitral valve becomes involved in structural change. Of thirteen cases of heart disease associated with scarlatina, which came under Dr. Sausom's care, there were three cases of pericarditis; one case was uncomplicated, and two cases were complicated with endocarditis (mitral regurgitation). There were ten cases of endocarditis, including mitral regurgitation in eight cases, one case of dilatation of left and right cavities, mitral stenosis in one case, mitral stenosis and regurgitation one case. In six cases of heart disease associated with measles, there was pericarditis with endocarditis (mitral regurgitation) in one case; endocarditis inducing mitral regurgitation in three cases. In one case hypertrophy and dilatation; in one case tricuspid insufficiency. In one case mitral stenosis; in one case mitral stenosis and regurgitation. (d)

Dr. Dyce Duckworth has collected eighty cases of mitral stenosis, of which only seventeen were males; the oldest patient was 63, the youngest (a girl) 14; the majority of the cases occurred between the ages of 25 and 35. He arrives at the conclusion that two-thirds of the cases had a rheumatic origin, and that fright, strain, and other injuries are to be enumerated among the list of causes, or rather as the writer observes, the valve not being healthy, these special causes were enough to aggravate the condition which already existed. Slow degenerative changes

(a) "A girl, *æt.* 13, of rickety constitution, was admitted into the Samaritan Hospital under my care in November, 1878, with symptoms of mitral stenosis. There was no history of rheumatism or chorea, the disease being probably congenital. Two years previously she had a severe cough, and threw up a good deal of blood. Now the lungs gave some proof of hyperæmia and congestion. The heart's action was thumping and sudden; dulness extended to the sixth interspace below, a little external to the nipple line, and in the direction of the epigastrium. There was some hypertrophy and dilatation on the left side of the heart. There was no thrill, but a very distinct presystolic murmur limited to the area of the cardiac apex of a cantering sonorous character, fading in force towards its termination, like a sound dying away in the distance. It was well vocalised by the letters *R r r* or *V o o* as Dr. Balfour has pointed out (*Op. Cit.*, page 110). A louder and different murmur was heard posteriorly, and in the axillary line, also in diminished force over the right chest and back; it was systolic, and had all the characters of a mitral regurgitant murmur. The pulse averaged 90; it was jerking, weak, and wavy, but regular."

(b) Balfour, *op. cit.*, p. 103.

(c) "Diseases of the Heart and Aorta," 1875. P. 315.

(d) Clinical Lectures "On Diseases of the Heart in Childhood."—*Medical Times and Gazette*, October, 1879. P. 471.

in the mitral valve leading to stenosis are, I think rightly considered, not uncommon. (a) In the cases of two girls, affected with mitral stenosis, who came under my notice, aged respectively 13 and 17, there was no history of rheumatism, nor of any illness that could account for this grave cardiac condition. Of the above eighty cases, six only were traceable to chorea. Of sixty-one fatal cases of chorea mentioned by Dr. Hilton Fagge, there were only two in which all the valves of the heart were perfectly healthy. (b)

*Treatment of Valvular Diseases.*—This is at best but unsatisfactory. We cannot restore the injured valve in its integrity, but we can foster the growth of hypertrophy, and in some fortunate cases even restore the ventricular chamber to its normal size. The symptoms which arise as a consequence of these organic changes are best relieved by rest, and the avoidance of exercise and excitement. By maintaining the general strength and guarding against local congestions and inflammatory attacks, we may often succeed in giving a fair share of health and comfort to children, while warm clothing (particularly cotton-wool or flannel worn over the chest), nutritious food, and active aperients will tend to keep in check some of the worst symptoms, as dropsy, when they show themselves. If congestion of the lungs, or bronchitis occur, squill, carbonate of ammonia, belladonna, strychnia, and other stimulating expectorants and sinapisms will be indicated.

When the heart is getting weak and quick in mitral disease, and there is a tendency to dilatation of the right cavities, the tincture of digitalis administered in gradually increasing doses will improve the tone and fullness of the pulse beat, reduce the frequency of the heart's action, and cause the over-distended cavities to contract more vigorously on their contents. Instead, therefore, of blood accumulating in the heart during diastole, a larger quantity is expelled at each contraction of the ventricle. Digitalis has been said to increase the discharge of urine, but there is some doubt about this so long as low arterial tension remains unaffected. I carefully measured the quantity passed in two cases of mitral regurgitation in children with dilatation of the right ventricle, yet in neither was there any appreciable difference in the amount passed, nor any change in its quality. They were in no way improved by the drug. Traube first noticed that the fall of the pulse rate, and the rise of arterial tension during the employment of digitalis, are attended with an increased amount of urine.

In nearly all the cases in which I have given digitalis for the heart affections of children I have combined it with iron, and frequently with strychnia also. Iron improves the quality of the blood, and the muscular power of the heart. Digitalis is of most value in simple dilatation from debility in the cardiac muscle, and in both forms of mitral disease, where weakness and irregularity of the pulse are present. It may be given with advantage in dilatation with hypertrophy, but not in the latter form of heart affection alone. If nausea, headache, or unsteadiness of pulse should come on during the employment of digitalis, the drug should be intermitted for awhile.

In certain rickety children with thoracic deformity, with twisting of the aorta, hypertrophy of the left ventricle is early developed (Rokitanski), and in some cases even valvular disease (Hilton Fagge). In these cases cardiac failure is early developed.

Heart cough is common in adults in the failing stages of heart disease, and is usually found in children with heart disease at any stage. It is the result of congestion of the pulmonic circulation; it is aggravated by sedatives like paregoric, and even by bromide of potassium; it is effectually relieved by cardiac tonics like digitalis com-

bined with iron, and when very troublesome it is well to put the patient to bed with complete rest for a week or two.

(To be continued.)

### COLLES'S FRACTURE. (a)

By JOHN W. KNOTT, L.R.C.S.I.

A SHORT time since the body of a female subject was brought into the dissecting room of the College of Surgeons' School, in which the radius of each side was found to present the evidence of former fracture of the lower extremity, united with unreduced deformity, and I thought that a description of the specimens might be worth bringing under the notice of the Surgical Society, as both presented peculiarities which contrasted with the usual and typical form of fracture occurring in this situation, and with which the name of one of the greatest of Irish surgeons is so deservedly connected. I also thought the occasion a favourable one for giving a short *resumé* of the literature of the subject, on which it is said that more has been written than on any other similar lesion occurring in the human body.

Of the pair of specimens in question, the radius of the right side had been the seat of an oblique fracture, the obliquity, as is usually the case, running from above and behind downwards and forwards, but at a much higher level than is generally seen, the line of fracture being in front, an inch and three-quarters above the carpal extremity of the bone, whilst on the posterior aspect, it reached to a little more than two inches from the articular margin. The lower fragment had been, so far as I could make out, simply hinged backwards with the slightest possible amount of separation of the broken surfaces, and a vertical antero-posterior section showed no trace of the line of compact tissue imbedded in the spongy structure of the lower fragment, which was believed by Voillemier to be conclusive evidence of impaction. The carpal fragment had also undergone the peculiar form of rotation described by Goyrand, in which the triangular fibro-cartilage forms the radius of a circle, of which the lower piece of the broken bones describes an arc during the progress of displacement, so that the outer side of the lower fragment is carried further backwards than the inner. A remarkable complication existed in the form of a dislocation of the scaphoid bone, which had been rotated on its vertical axis, so that the tuberosity looked backwards and outwards, forming a prominence below and a little behind, the styloid process of the radius.

The fracture on the left side had been at a low level, the solution of continuity being placed in front about an inch above the lower end, while it reached about one-third higher posteriorly. On neither side did any evidence of impaction exist, but this is not to be wondered at, as even Voillemier himself, the great apostle of the impaction theory, says that it is not to be expected in fractures more than an inch or so above the articular extremity.

Although the name of Colles is in this country invariably associated with the usual form of solution of continuity of the lower end of the radius, the frequency of the occurrence of fracture in this locality was pointed out long before by Ponteau, whose description of the signs of this lesion in the second vol. of his "*Œuvres Posthumes*," will be found to contain a very excellent description of the most prominent local signs of the lesion. His pithy remarks that this is of all fractures the one in which a diagnosis can be most certainly made by a single *coup d'œil*, has become a household word in surgery; but his theory of the mechanism of the fracture, that it was due to a spasmodic contraction of the pronator and supinator muscles of the forearm, will not find many supporters at the present day. He ingeniously compares the articulated

bones of the forearm to a segment of a circle, of which the arc is represented by the radius, whilst the chord is formed by the ulna, and so demonstrates—to his own satisfaction, at least—that the action of the pronator muscles on the curved bone in approximating the fragments to the ulna, must be to produce lengthening of the broken radius. To this imaginary lengthening it is that he attributed the peculiar displacement of the carpus which he mentions as the first of the characteristic signs of the lesion. The other typical changes which he enumerates are, the tumour on the palmar aspect of the forearm, caused, as he thought, by contraction of the pronator quadratus, throwing forwards the flexor tendons; thirdly, diminished breadth of the forearm at the seat of fracture from the action of the same muscle causing approximation of the fragments, and consequent obliteration of the inter-osseous space; and fourthly, increased size of the wrist, produced by the *mouvement de la vasculæ*, communicated to the styloid process of the broken bone.

He also remarks that it is not necessary to expect much displacement, but a depression of the arch at the seat of fracture, which is aptly compared to the lezarde or baillement of architectural ornamentation.

Yet, strange to say, notwithstanding Ponteau's recognition of the importance and frequency of fractures of the lower end of the radius, we find his teaching on the subject absolutely ignored by subsequent authorities in French surgery for a very considerable period. Boyer writing in 1833 (a) and subsequently in 1820 (b) does not seem to be aware of the existence of such a lesion, and although he speaks of fractures of the radius produced by a fall on the hand, he places the seat at the centre of the shaft of the bone.

In Desault's *Journal de Chirurgie* in 1790, there had appeared, indeed, a record of a single case of fracture of the lower end of the radius, observed by Herne, but the case is merely noted, without further comment, and the writer does not make the smallest allusion to Ponteau's description. Most of the leading surgical authorities of the time followed the old errors; the four luxations of the wrist were unanimously recognised, their characteristic signs pointed out, and appropriate treatment recommended.

It was in 1820 that Dupuytren, by the immense influence of his writings and lectures, succeeded in establishing—for French surgeons at least—the non-existence of luxation of the wrist, of which he had never seen an example throughout the whole of his enormous experience; and the frequency of fractures of the carpal extremity of the radius, which formed a fifth of the cases occurring in his practice. So completely was the work of foreigners in this direction ignored by French writers, that we find Voillemier, in 1842, giving Dupuytren the credit of having created, so to speak, fracture of the lower end of the radius.

It was in 1814 the short but valuable description of Professor Colles appeared in the pages of the *Edinburgh Medical and Surgical Journal*, and with the exception of the single point of his localisation of the level of the seat of fracture, which he placed an inch and a-half above the carpal extremity of the bone, his account of the lesion has suffered but little at the hands of subsequent critics. Colles was not then aware that any previous account had been published, and wished to call the attention of surgeons to the frequency of the occurrence of a solution of continuity of the lower end of the radius, and the extreme infrequency of the forward (or so-called Desault's) dislocation of the carpal extremity of this bone, for which this injury had been mistaken, because of the "absence of crepitus" and other signs of fracture, together with the swelling which instantly arises in this as in other injuries of the wrist, render the difficulty of ascertaining the real nature of the case very considerable. He points out the depression which is seen about an inch and a-half above the end of the radius, the swelling and backward displace-

ment of the wrist and metacarpus, the fulness of the anterior surface of the forearm limited below by the anterior annular ligament of the wrist, and apparently caused by the flexor tendons being thrown forwards, and the projection of the lower end of the ulna towards the palm and inner side, to a degree varying in different instances. The lower end of this bone can also be moved backwards with abnormal facility; but an examination of the radius at the seat of fracture fails to detect either crepitus or yielding of the fragments till extension is made, so as to restore the limb to its natural form, when a backward and forward movement will be found to cause a sensible yielding of the broken surfaces. The inward projection of the lower end of the ulna he attributed to the pressure of the upper end of the carpal fragment of the radius, the yielding of the other bone being facilitated by laceration of the ligaments of the inferior radio-ulnar articulation. Such is Colles's account of his own fracture. Imperfect it of course is, but for an original description we cannot but admire the sagacity with which he appreciated, and the happy simplicity and clearness of language with which he detailed, the diagnostic value of the local signs of this lesion.

The teaching of Pontean in France, and of Colles in this country, was comparatively neglected till the subject was revived by Dupuytren, and by R. W. Smith, and it is indeed to the widespread influence of the opinions and writings of these eminent surgeons that may chiefly be attributed the prominence which has been accorded in the literature of the profession since their time to the consideration of this, the most frequent—at least, according to some authorities—of the fractures that have been met with in the human skeleton.

While Colles had contented himself with pointing out the comparative frequency of fracture, and the rare occurrence of dislocation, Dupuytren went so far as to doubt—although not of course absolutely deny—the possibility of the occurrence of a luxation occurring at the radio-carpal articulation, and amusing stories are still recorded of the fierce clinical dispute which sometimes took place on the subject, even in presence of the patients, between the hot-tempered surgeon of the Hotel Dieu and his colleagues, Pelletan and Marjolin, both of whom remained for a long time orthodox believers in the errors which had been impressed on them by their earliest surgical teachers. In one case a man who had fallen on the extended hand was brought into the hospital presenting the characteristic deformity of the lower end of the forearm, and the case was examined by both Marjolin and Dupuytren. The former diagnosed a luxation of the carpal; the latter a fracture of the radius. Neither was disposed to yield in the least to the opinion of the other, when an opportunity was afforded of settling the point by the death of the patient from some intercurrent disease. The autopsy was made in the presence of the two champions. The victory remained with Dupuytren.

In the description which is published in the *Lancette Francaise* in the year 1820, he notices the change in the axis of the fore-arm, and also in that of the hand, which is carried to the radial side by a movement of *abduction de totalité*. The projection of the lower end of the ulna he refers to the displacement of the hand. He points out the anterior and posterior tumours, the former of which he refers to the angular projection of the fragments in front, and the latter to the prominence of the carpus behind. He also adds that in those cases where an opportunity had been afforded of examining the recent specimen, he always found the inferior fragment divided by radiating lines into several pieces, as if it had been violently struck with a hammer, a condition to which he applied the term, *fracture par ecrasement*. He places the seat of fracture at two or three lines, up to half an inch, rarely so high as an inch or more, above the lower end of the bone, but makes no reference to the obliquity of the line of fracture. In the *Lecor's Orales* he points out the remarkable analogy which exists between this fracture and that of the lower end of the fibula, with which the

name of Pott is now so generally associated, and traces the prominent points of resemblance of the two lesions. The abduction of the hand in one case, is compared to the eversion of the foot in the other. The projection of the lower end of the ulna has its counterpart in the prominence of the inferior extremity of the tibia; the depression at the seat of the radial fracture resembles the *coup de hache* which is found above the external malleolus; while the action of the long abductor muscle of the thumb (extensor ossis metacarpi pollicis) is supposed to have an influence on the carpal deformity in the case of the lesion of the upper extremity similar to that which is exercised on the distortion of the foot by the peronei muscles in case of a solution of continuity of the lower end of the fibula.

The fact that the radius alone gives way, Dupuytren accounts for by observing that it is the bone which offers the greater resistance, as it only articulates with the wrist, and accordingly deserves the name, which was given to it by the old anatomists, of *manubrium manus*. By this anatomical arrangement the radius is made to receive all the force which is communicated to the upper extremity by a fall on the hand. The situation of the fracture at the lower end, in spite of the greater thickness and apparent strength, will be understood when it is remembered that the whole violence of the shock is concentrated on that part of the bone, and that the increased thickness does not by any means denote greater solidity, as the osseous tissue at the favourite seat of the lesion is almost purely cancellous. The liability to fracture is also vastly increased by the almost complete impossibility of dislocation, which is explained by the immense resisting power offered by the tendons, both flexors and extensors, which are closely applied to the surfaces of the radio-carpal articulation. If, as the writer believes, a force of 2,000 lbs. would be insufficient to overcome the resistance, a fall under ordinary circumstances will fail to do so, for the momentum or moving force, calculated by multiplying the weight of the body by the velocity of the fall, will not, except in cases where it has been from a great height, give so large a figure as the one mentioned. A violent fall on the hand, then, if not followed by a dislocation of both bones backwards at the elbow joint, nearly always produces a fracture of the lower end of the radius. Sometimes the result may be found to be a severe sprain of the wrist-joint, or fracture of some of the phalanges or metacarpal bones, but these are not often seen.

The example of M. Bouchet, who, in his thesis, published in 1834, gave the results of a series of experiments on the cadaver, was followed by a host of other inquirers, who endeavoured, by this method, to throw some new light on the mechanism of this still obscure lesion. Goyrand (d'Aix), had, indeed, been in the field before him, but had not done so much. He, however, made his views and experiments, the subject of a very valuable communication to the *Gazette Medicale* in the year 1832. He lays great stress on a point which had been neglected by Dupuytren, that is, the obliquity of the line of fracture, which, according to him, takes, in nineteen cases out of twenty, a direction from above and behind, downwards and forwards. He also makes three varieties of this fracture (1) by far the most frequent in which the line of fracture runs obliquely from behind downwards and forwards; (2) comparatively rare, in which the line of obliquity runs from the anterior aspect of the bone downwards and backwards; and (3) the *en toile* of Dupuytren. In the first of these forms the lower fragment glides on the inclined plane formed by the oblique surface of the other, and so becomes displaced upwards as well as backwards, either by muscular action alone, or by the violence which had produced the fracture persisting after the solution of continuity had been established. In the latter case the displacement, of course, would be much more considerable. At the same time, as the lower fragment is still tied to the ulna by the triangular fibro-cartilage, it is obliged to undergo a rotatory movement, in which it describes an arc of a circle, of which the radius is formed by the fibro-

cartilage, the centre being at the ulnar extremity of the same. By this double movement, the articular surface undergoes a change of direction, so that instead of looking forwards and inwards, it becomes inclined backwards and outwards. In the second form of fracture, analogous phenomena are met with, excepting that the forward deviation of the lower fragment is less pronounced than the backward in the other case, and that the direction of the articular surface is turned still more forwards than in the normal condition. With regard to the abduction of the hand, he expresses very strongly an opinion directly opposed to that of Dupuytren, who looked upon this deformity as one of the most characteristic signs of fracture of the lower end of the radius. Goyrand, on the other hand, considers its occurrence to be quite exceptional, and insists that so long as the internal lateral ligament of the wrist and styloid process of ulna remain whole, the hand will be found to be inclined not outwards but inwards; whilst he admits that in the rarer cases in which the ligament has been torn by an extreme amount of violence, or the styloid process wrenched from the head of the ulna, the axis of the displaced hand will be found to have undergone some deviation to the radial side of the forearm. The mechanism of the fracture is referred by this writer to *contre-coup*. In a fall on the palm of the hand the whole weight of the body is thrown on the upper extremity. The carpus, broken up into a great number of pieces, movable articulations decomposes the shock, and resists it, but the radius, pressed between the weight of the body, and the carpus, supported by the ground, receives the transmitted force at its inferior extremity, where from the sponginess of its structure, it is least able to resist. The opinion of Goyrand on the relative frequency of this fracture is somewhat remarkable, for he soundly asserts that the number of specimens admitted to the Hôpital d'Aix, bore to the number of all other fractures taken together, the proportion of one to two, at the same time observing that many genuine cases escaped observation, because the patients looking upon the injury as a sprain did not apply at the hospital for surgical assistance.

(To be continued.)

## Clinical Records.

### ST. MARY'S HOSPITAL.

*Abscess and Caries of Head of Tibia—Result of an Injury—Trephining—Removal of Sequestrum.*

Under the care of A. T. NORTON, F.R.C.S.

THE patient, a strong healthy looking man, æt. 27, injured the upper extremity of his left tibia by a fall from a cart about fourteen years ago. He was laid up for three months, after which he seemed to have completely recovered.

Last summer ("1879") he struck the same spot with a hammer; he did not take much notice of the injury however, but went to work as usual.

In July, "1879," the seat of former injury became painful, and continued so with some variation till September 18th, 1880, when he was admitted to the Hospital.

On examination, it was found that necrosis had taken place in the upper extremity of tibia.

On the 23rd of September the patient was taken to the theatre, chloroform was administered, the trephine employed, and a sequestrum removed. The wound was dressed with antiseptic marine lint, and syringed with carbolic lotion, a back splint being also supplied. The temperature remained at 98° 8'.

On the 24th the wound was dressed, as on the 23rd pain was gone. Temperature in the morning, 97° 6'; evening, 99°, which, with the evening of the 28th, when it was 99°, were the two highest temperatures recorded.

On the 30th the wound was dressed as before, with the addition of a drainage-tube in the cavity.

The dressings were continued the same way till Nov. 1st,

when the drainage-tube was cut short, the wound filling up with granulations.

On the 12th the patient was discharged apparently cured.

After leaving hospital suppuration again commenced, and a small opening formed through which the probe could be passed into the position of the former cavity where it came in contact with some carious bone tissue. He was, therefore, re-admitted on the 14th December. The former cavity was laid open by a simple incision and plugged with carbolic lint.

Jan. 1st, 1881.—No bone came away in quantity after re-admission, but healthy granulations sprang up absorbing what remained of the carious tissue.

On the 8th January the probe would no longer reach any grating material, and the wound was healing well and rapidly from the bottom. The plug of carbolic lint was inserted only into the mouth of the wound until its complete closure.

## Department of Lunacy.

### THE STAFFORD COUNTY ASYLUM AT LICHFIELD.

DR. DAVIS, the Medical Superintendent of the Stafford County Asylum at Lichfield, who is about to retire from that position on a pension, and who is to be succeeded by Dr. Spence, Assistant Medical Officer at the Idiot Asylum at Earlswood, does not err in his last annual report in the way of publicity or premature publication, that for the year 1879 having just reached us, and being confined, as far as Dr. Davis's contribution to it is concerned, to half a dozen brief and heavily loaded sentences. From the Report of the Visiting Commissioners in Lunacy, and from the tables appended, we learn that the Asylum contained at the end of 1879 511 patients, that the death-rate during that year was 16'01, calculated on the average daily number resident, which is so high as to call, we think, for special explanation which is not offered, and that the rate of recovery during that year was 24'95, calculated on the admissions, which is exceptionally low. The cost of maintenance of each patient per week was 8s. 11½d., of which amount 4s. 8½d. went for provisions. The diet table looks sufficient on paper, but wherever an asylum death-rate is high the manner in which the diet table is practically carried out in the stores and kitchen should be the subject of careful and independent scrutiny. One patient suffered from small-pox, but his immediate isolation prevented the propagation of the disease.

### THE SURREY COUNTY ASYLUM.

DR. BRUSHFIELD's reports are always clear and interesting and that for the year 1879, and bringing down the history of the Surrey County Asylum to the beginning of the present year, contains much peculiarly instructive matter. Bound up with it there is a special report to which we have given separate consideration, on the question of substituting non-stimulants for beer in the asylum dietary. The report itself shows that on the 1st January, 1879, there were 1,012 patients in the asylum, that 337 were admitted during the year, and that 191 having been discharged, and 117 having died, there remained on the 31st of December 1,061. Amongst the admissions there was a marked increase in the number of cases of general paralysis, and a diminution in the number of cases of epilepsy. More than one third of the total number of

deaths occurring in the asylum during the year were attributable to general paralysis. The recoveries were at the rate of 34·17 per cent. of the admissions, and included a case of complete restoration to reason after insanity of ten years' duration. A number of criminal lunatics, whose term of imprisonment had expired, were sent to the asylum during the year 1879, and with respect to these Dr. Brushfield says that while some of them had unquestionably become criminals owing to their insanity, others were criminals, independently of their insanity, to all intents and purposes. They had all the low propensities, and used the coarse and peculiar language customary among persons of that class, and were therefore undesirable companions for those patients of more refined habits and virtuous inclinations who were compelled to associate with them in the asylum wards. One wretched patient was received from Wandsworth Prison on April 28th, having been convicted on the 2nd of April of assault and aggravated assault, and sentenced to two consecutive sentences of six months each. He died of general paralysis on the 25th of May, that is to say, within a month of his admission, and two months of his conviction and sentence. Dr. Brushfield thinks, and no one familiar with the history of general paralysis will have any hesitation in agreeing with him, that this man was insane when he was tried, and insane when he committed the breaches of the peace for which he was punished. He was therefore solemnly tried, convicted, and imprisoned, when sinking under a fatal disease of the brain, for acts which were probably scarcely consciously performed. All such cases, and we are afraid they are of not infrequent occurrence, should be specially brought under the notice of the Home Secretary, so that some account may be required of the magistrate and officials who have played a part in such a grim farce. Only under a wholesale and rough and ready system of judicature could such cruel miscarriages of justice occur.

## Transactions of Societies.

### SURGICAL SOCIETY OF IRELAND.

SESSION OF 1880-81.

A MEETING of the Surgical Society was held on Friday evening, 7th inst., in the Albert Hall, Royal College of Surgeons. Dr. E. D. MAPOTHER, senior member of Council of the Society, in the Chair.

Mr. B. WILLS RICHARDSON, Hon. Sec., read the minutes of the previous meeting, which were confirmed.

Mr. WILLIAM WHEELER exhibited a conical bullet which he had removed from a gentleman on the 2nd inst. The history of the case was simply this:—The gentleman, being a landlord, had purchased a revolver for the purpose of defending himself on his return to the country. On the evening of the 2nd inst. he was sitting with his legs elevated at one side of the mantelpiece. A friend of his who happened to visit him was admiring the revolver, of which two barrels were loaded. Taking the revolver in his hand, one of the charges went off, and hit the owner of the weapon, entering close to the trochanter major. The bullet, impinging on the trochanter major, was deflected, and passed upwards and backwards, towards the sacrum. Called in by a medical man who was present, he (Mr. Wheeler) found the patient in a state of intense alarm, and stating that he was dying. However, his pulse was good, and there was no reason to fear that he would die. Having ascertained exactly where he had

been shot, he passed a long probe into the opening, following the track of the bullet, which he hit without much difficulty. The probe passed beyond the bullet, and touched the skin. Knowing that bullets often changed their situation, he at once cut down upon it, and, seizing it with a forceps, extracted it. The upper part of the trochanter was not injured, which might be expected, the bullet being conical. The initial velocity of the bullet must have been at the rate of 300 miles an hour. Taking as data that the old musket used at the Crimea projected bullets at a velocity of about 850 miles an hour, and calculating the quantity of powder that expelled the one, and the proportion it bore to the quantity of powder which expelled the other, he arrived at the result mentioned. Of course by such method of calculation one could only approximate. Intense pain was felt along the track of the bullet and underneath the site of it, but on its removal the pain ceased. There was very little hæmorrhage—merely what he could easily stop with pressure. The patient is rapidly recovering.

Mr. W. THOMSON read a communication on

#### PARTIAL EXCISION OF THE TONGUE,

which will be found at page 66.

The CHAIRMAN (Dr. Mapother) observed that in the hospital to which for a great many years he belonged, a large number of cases of cancer of the tongue and other organs annually presented themselves for surgical treatment. He at once acknowledged that they had been unsuccessful in preventing the return of the disease by the removal of portions of the tongue. There was not the least doubt that most of the cases had been of the true scirrhus type, and by no means epithelial. Most had developed hard glands in the sub-maxillary and sub-lingual regions. Of five operations he could call to mind but a single instance where the disease did not return. So impressed was he with the liability of the disease to return that four years ago, in a case he saw with Dr. Robert McDonnell, although the cancer was confined to the anterior fourth, they both expressed the opinion that removal was unadvisable; and death rapidly ensued in four weeks afterwards, consequent on the rapid extension backwards of the disease.

Dr. J. K. BARTON said the subject of the communication was one of great surgical interest. Surgeons were very slow in adopting operative procedure, feeling it safer to let those cases alone. He thought that Mr. Thomson had done well in bringing the subject forward in order to add as much as possible to their facts, and to clear away the doubt and difficulty that hung over the treatment of such cases. There had been so many instances of the return of disease shortly after removal that operative treatment had become very discouraging. But he thought that advance was to be made, and greater success hereafter attained by following the methods pointed out in Mr. Thomson's paper. Some three years ago he had himself a case—that of an old man—the carcinomatous disease occupying the posterior part of the right half of the tongue. As far as he could form an opinion at the time, it was epithelioma, and was exceedingly hard, but very limited. He operated by means of the thermo-cautery, and the tongue was easily cut. There was moderate hæmorrhage. The operation was readily and successfully performed, and he was enabled to see what he was about. The case was interesting as the mode adopted had been referred to by Dr. Thomson with commendation. Moreover, the patient was nearly eighty years of age at the time, and two years afterwards he (Dr. Barton) heard of him as being perfectly well.

Mr. W. THORNTON STOKER held a very strong opinion of the value of the thermo-cautery in this and a number of cases in which it had been used. He had himself employed the three methods spoken of by Mr. Thomson in removing a portion or the whole of the tongue, but only in one instance had he used a ligature for removing a cancerous tongue—it was his first case, and the last. He looked on it as a relic of barbarous surgery, which he trusted never to see employed again. It had an objection even greater than Mr. Thomson had referred to when he spoke of the disgusting slough occupying the mouth of the unfortunate patient—and this he had himself had experience of—the ligature would eat into the surface of the tongue; and, in his opinion, no matter how tightly applied, it became loosened, and the result was that a secondary operation had to be performed to strangulate what the surgeon had failed to strangulate in the first attempt. With regard to the use of the écraseur, it should be employed only when applied to the anterior surface of the tongue, and there

was a perfectly clear isthmus attached to the hyoid surface of the bone; but cancerous disease was seldom confined to the anterior part of the organ. The *écraseur*, once applied, cut straight through the tissues; so that to avoid the risk of hæmorrhage—which was a recommendation of the *écraseur*—it took an extraordinary time to remove the tongue (from an hour to an hour-and-a-half). He had seen a patient in a half-anæsthetic state for an hour-and-a-half, whilst the tongue was being strangled by that cruel instrument. But the *thermo-cautère* he had used in such a way as to remove all diseased tissue in one or two minutes, rapidly and bloodlessly except so far as large vessels were concerned, and it left a healthy and clean surface behind which could be inspected or examined with the finger, enabling the surgeon to scoop out any traces of disease that might have escaped the first incision. He did not believe there was any greater risk of secondary hæmorrhage after the *thermo-cautère* than there was after the *écraseur*. There was no method by which all risk of secondary hæmorrhage was removed, and he thought the *thermo-cautère*, if properly applied, avoids the risk of secondary hæmorrhage as much as any other.

Mr. W. WHEELER said he had operated on several cases of cancer of the tongue, one complete removal of it, in which he was assisted by Mr. Tufnell, and several cases of partial removal. He remembered accurately the case Mr. Stoker had alluded to of ligaturing the tongue, it was performed in Baggot Street Hospital, and certainly it was not satisfactory. With Mr. Stoker he therefore entirely condemned that mode of procedure. But he did not agree with Mr. Stoker in saying the ligature would cut through leaving portions of the part intended to be strangled still supplied with blood, unless too large a portion was included. By applying two ligatures instead of one the part would be cut away only with the disadvantage of having the slough remain in the mouth, a great disadvantage no doubt, and having regard to which no one would now adopt that method. He concurred in Mr. Thomson's views with regard to the excision of the tongue by means of the platinum knife or *thermo-cautère*, but he could not agree with him in the disparaging manner in which he spoke of the *écraseur*. He himself had adopted the method attributed to Collis, of dividing the cheek, and the attachment of the floor of the mouth he separated by means of the *écraseur*, and then he cut the tongue across with the platinum knife, but there was a severe spout of hæmorrhage. Mr. Tufnell, from whom he had had a communication on the subject, thought the hæmorrhage was from the lingual artery, and he (Mr. Wheeler) caught it and tied it. There was no more hæmorrhage from that vessel, but in eight or nine days afterwards there was secondary hæmorrhage from the other side. Therefore, he took it from that result alone that the cautery was not as good a way of stopping the hæmorrhage as the ligature. In that particular case the disease occupied the whole of the anterior surface of the tongue. Four years had since elapsed, and the patient, who was known to Mr. Tufnell, was still alive and well. Another reason why he did not speak so disparagingly of the *écraseur*, as Mr. Thomson had done, was this: that by adopting the plan Bryant recommended, viz., putting pins in and transfixing the tongue, and using the *écraseur*, beyond that the surgeon would get completely behind the disease, and would not cut into the diseased surface, but through healthy structures. Though he was not advocating the *écraseur*, he did not think it should be disparaged, as it was a useful instrument. His plan would be to separate the floor of the mouth with the *écraseur*, and then cut across with the hot knife, as in the case he had mentioned. The reason there were so many unfavourable results in partial removal of the tongue was that the operator did not cut far enough back. It was to insufficient examination rapid returns and unsuccessful results in the removal of the tongue must be often attributed. Surgeons did not remove sufficient of the tongue, and in cases of that kind there should be larger incisions than was recommended by Collis. In fact, Syme's method of cutting the lower lip and splitting the jaw to give room to get at the disease in order to remove every particle of it was quite legitimate.

Mr. THOMSON replied. The general tenour of the observations had been, he said, in the same line as that which he had himself travelled over. Mr. Wheeler did not seem to have noticed the fact of his having stated that he adopted the plan of transfixing the tongue when he used the *écraseur*. He inserted needles to prevent the loop of the chain slipping forward and passing through the diseased portion, at least

that discovered to be diseased on examination by the fingers. But even that method was not safe or reliable, and did not remove the objection he had indicated. Suppose when cutting through the tongue with the *écraseur*, the surgeon found he had passed through the middle of a diseased nodule, there was no provision to remove what remained but by going over the same operation again, occupying over half an hour. So far as that contingency was concerned the platinum knife had a vast advantage over the *écraseur*. As to hæmorrhage, plenty of cases could be noted where there was immediate hæmorrhage after the use of the *écraseur*, and also secondary hæmorrhage. That was an unfortunate danger of all operations, no matter what care was taken, and on that account there was no reason for pre-eminence of the *écraseur* over the platinum knife. Dr. Barton's case was one of extreme interest, not only because of the method employed, but the result of it. Mr. Stoker had condemned the use of the ligature from his own experience, but he did not agree in what he said as to using the *écraseur* in cases where the disease was confined to the anterior portion of the tongue. His (Mr. Thomson's) objection would apply to the removal of any portion of the tongue, the process was tedious, and did not save them from secondary hæmorrhage. If the disease was in a free portion of the tongue, the anterior part, the cautère was the instrument which would give the best results. Mr. Wheeler and Dr. Barton had both concurred in the view that he tried to press, namely, that they were entirely too limited in their operations of removing portions of the tongue. If he had to do his first case over again, the operation would certainly be a more radical one than it was.

Mr. KNOTT read a paper on the subject of

COLLES'S FRACTURE,

which appears at page 69.

Dr. BENNETT regretted that an accident prevented the discussion of the paper having the interest it otherwise would; for the specimens which Mr. Knott intended to present as the foundation of it had come to an untimely end. Thus the Society had the sermon without the text. The first point worthy of remark was in reference to the specimens but which could not be verified now. In describing them as specimens of Colles's fracture, Mr. Knott localised one of the fractures as being an inch and a-half or more than that above the level of the radial carpal surface. But whether rightly or wrongly, it had been the habit to exclude such specimens from the category of Colles's fracture, and to include those that fell within the distance of under an inch and three-quarters of the carpal extremity. Therefore it was open to question whether or not the data on which the facts of the paper were strung were cases of Colles's fracture at all; and the question of their being oblique or transverse fractures depended on the solution of that point. He had himself published statistics of those injuries far more than had hitherto been collected; and fractures of the radius within the limit of an inch, and close above it, he had been careful to exclude all such from the category of Colles's fracture. On that point he would be glad of an explanation, as it was well to be exact on the limits to which the discussion applied.

Mr. WHEELER congratulated Mr. Knott on his excellent and exhaustive paper, and pointed out that he had excluded the fractures referred to by Dr. Bennett from the class of Colles's fracture as being above three-quarters of an inch.

Dr. BENNETT said the paper appeared to be founded on two cases of Colles's fracture recently dissected.

The PRESIDENT.—The title is undoubtedly that of "Colles's Fracture."

Mr. RAWDON MACNAMARA observed that it was most extraordinary how deficient the museum of the College was in specimens of the fracture which had received the name of the great Irish surgeon, Colles. When he heard that three cases of Colles's fracture were to be brought before the Society, he rejoiced in the idea that the museum was to be so enriched; but he was now sorry to hear a gentleman boast of a large number coming under his observation without enriching their national museum of specimens. Over and over again the Council had represented their anxiety to get them, and he was sure now that the matter was brought before the members of the Society they would contribute specimens.

Dr. BENNETT said he happened to know the collection in the museum better than Mr. Macnamara did, and it contained the finest specimens—he did not mean in great number—but some of the most typical to be found in any museum.

Mr. MACNAMARA.—How many?

Mr. W. THORNLEY STOKER.—Five.

Mr. MACNAMARA.—They are very few.

Dr. ABRAHAMS said he had had an opportunity of examining Mr. Knott's specimens, and he corroborated all he had said about them as regarded the position of the fracture.

Mr. KNOTT replied. He did not consider the fractures as typical Colles's fractures, and he had in his paper pointed out their peculiar position as being much higher than the typical ones, excluding those above an inch. Colles himself had located them at an inch and a-half, but the typical ones were lower down.

The Society then adjourned.

“SALUS POPULI SUPREMA LEX.

WEDNESDAY, JANUARY 26, 1881.

### INUNDATION AND INFLAMMATION.

It is to be expected that among the sequæ to be anticipated as the consequences of the run of severe weather we have lately experienced, augmentation of the death-rate will not be the least important and striking. Not perhaps so forcibly as occurred in 1880, shall we be reminded of the fatal influence exerted by the winter changes on the susceptible and the aged, since the unprecedented fogs of last winter are accountable for the unusual mortality which was registered in the early part of the year; and from the nature of the diseases to which they gave rise, it was not in any way difficult to trace a direct connection between the fog and the prevailing illnesses of the time. The first months of 1881 will, we fear, be similarly distinguished from the later periods by the high number of deaths that will probably take place within the areas of the metropolis and other large towns. And in a similar fashion, too, we doubt not it may be shown that by no means a small proportion of the illness to be expected, will be of the kind influenced and set up by conditions that should be practically avoidable by a

civilised and enlightened State. At this moment there are very large districts in London, Manchester, and other places, either under water, or but recently so; and in every one of these situations there are resident a large number of people who, but for the miserable shelter afforded by their drowned-out abodes, would be homeless. Not by ones, or tens, or even hundreds, but by thousands are these unfortunates to be counted; and we may well ask ourselves how comes it that this thing can be in the heart of the world's greatest city. Again and again have suggestions been made, to pass unheeded, for ensuring the future protection of the quarters subject to inundation; and again and again, in consequence of the supine indifference of authority to suffering in which it has no immediate share, have the floods been allowed free play where it had been comparatively easy to restrain them. It may be, of course, that there is no proper appreciation of the mischief produced by these overflows, and this, because it is not seen at once, save in the mere physical sense of discomfort and loss of goods. This, however, is only the least of the evils to be anticipated. Far graver, and far less easily remedied, are those constitutional infirmities encouraged, or initiated, by the untoward condition of exposure and damp. Not at once, when the water has receded, or been pumped from a house, are its inmates relieved of the danger to be dreaded from its presence. It is the after, slow, gradual drying which is the more prejudicial to life and health. For a protracted time exhalations of moisture, laden with every impurity to be found in the flood-soaked soil, finds its way through the walls and under the doors of every habitation built within their reach; and those living in such a region, though they may not, and often do not, heed or recognise the influence at work on them, yet do they none the less surely and certainly at length succumb to one or other of the deadly diseases to be dreaded in such situations. The pathological relations of inflammation are now sufficiently well understood for us to have no difficulty in tracing a causal connection between the inflammatory stages of constitutional disease, and those etiological conditions originated in districts which are, or have been, flooded. Nor, as a rule, are we at a loss to trace the consequences that are likely to follow any fresh occasion of flooding, such as those which have occurred in the south metropolitan district within the last few days. There is nothing in the history of the past to justify an anticipation of immunity in the future for those people who are subjected to malarial, or only merely cold and damp, exhalations. Rheumatismal, bronchitic, even typhoid affections are no uncommon attendants on the densely aggregated poor of London, but the tendency to contract any one of these will be infinitely greater now that the surroundings of the unfortunate dwellers in the crowded neighbourhoods of the river-side are so peculiarly fitted to harbour any chance disease brought there. Never, it must be said, sufficiently robust to meet a long-continued attack, the ordinary poor are peculiarly unfitted to undergo the peril they will pass through, the majority of them, it must be feared, with only meagre prospect of safely emerging therefrom.

Admitting all this, then, it does seem a strange and unnatural truth that the cause of it should be permitted to

continue, with full knowledge of the disastrous consequences to be dreaded. It is incomprehensible that remedial measures are omitted, sufficient to ensure, at least, that high tides shall not swamp those dwelling in the vicinity of the river banks; and that, at any rate the most obvious precautions against the injurious effects of the riparian exhalations should not be taken. When, however, no one of these conditions is observed, but the warning emphasised by each additional overflow, and echoed in the dying sighs of thousands who suffer through the negligence of a few is allowed to pass unheeded, it is then assuredly time that an emphatic protest should stir into action the apathy that has too long looked regardless and remorselessly on.

Efficient though it is, and all-willing, the medical service can do but a little in the way of relieving the necessities of the numbers who will so soon need the utmost help possible. The aid must come from another source, and to be real it must be practical, and end in the adoption and fulfilment of measures adequate to the total prevention of a recurrence of those inundations which leave behind them a rich and funereal legacy of constitutional inflammations.

#### THE NOTIFICATION OF INFECTIOUS DISEASE.

We printed last week the text of the Bill which is being promoted by the Dublin Corporation, and is fixed for its second reading on the 30th of March, and we pointed out:—

1. That it applies to the whole of Ireland.
2. That it is entirely permissive.
3. That it compels the physician attending an infectious case to send a written notice to the sanitary authority.
4. That the fee proposed to be paid to the physician for notifying is ludicrously small as his responsibilities under the Bill are great.

We said also, that the extent of the responsibilities of this Bill must be judged, not by the simple fact that notification of infection is to be compulsory, but by the consequential effects of that notification upon the house occupier, the patient, and the physician. Those effects are set forth in the sections of the Public Health (Ireland) Act, 1878, which set forth the part which the sanitary authority is to play on receiving the notification, and it is impossible for us to form a judgment as to the amount of inconvenience, loss and responsibility which the Bill imposes on the physician until we ascertain what it is which may follow upon the performance of his duty as a notifier of disease.

This information we learn from the 137th and following sections of the Public Health Act of 1878 (page 576, Irish Medical Directory). We give the words of the sections, omitting redundancies of phraseology.

Where any sanitary authority are of opinion, on the certificate of any qualified practitioner, that the disinfecting of any house, and of articles therein likely to retain infection, would tend to prevent disease, it shall be their duty to give notice to the owner or occupier, requiring him to cleanse and disinfect such house and articles within a time specified. . . . If the person fails to comply, he shall be liable to a penalty of 40s. for every day during default; and the authority shall cause such house and articles to be disinfected, and recover the ex-

penses in a summary manner. . . . Any authority may destroy any bedding, or other articles which have been exposed to infection, and may give compensation for the same. . . . Any person suffering from any dangerous infectious disorder, and without proper lodging, or lodged in a room occupied by other persons not so suffering, or is on board any ship or vessel, may, on a certificate signed by a medical practitioner, be removed to such hospital. . . . Any person who disobeys such order shall be liable to a penalty of £10. . . . Any person who—(1) while suffering from such disorder wilfully exposes himself in any street, public place, shop, inn, or public conveyance, or enters any public conveyance; or (2) being in charge of any person so suffering so exposes such sufferer; or (3) gives, lends, sells, transmits, or exposes, without previous disinfection, any bedding, which have been exposed to infection; or (4) conveys without proper precaution the body of any person who has died of any infectious disorder; (5) or permits to be waked, the body of such person shall be liable to a penalty of £5; and a person who, while suffering from such disorder, enters any public conveyance, may be summarily ejected therefrom, and shall pay to owner the amount of any loss and expense they may incur. . . . Any person who knowingly lets for hire any house, or part of a house in which any person has been suffering, without having such house, and all articles therein liable to retain infection, disinfected to the satisfaction of a medical practitioner, shall be liable to a penalty of £20. . . . The keepers of an inn or school shall be deemed to let for hire any house to any person admitted as a guest. . . . Any person showing for the purpose of letting for hire part of a house who, on being questioned as to the existence of infectious disease therein, within three months previously, knowingly makes a false answer, shall be liable to a penalty of £20, or to imprisonment with hard labour for one month. . . . Any person who shall knowingly send a child to school who, within three months, has been suffering, or who has been resident in any house in which such disorder shall have existed within six weeks, without a medical certificate, that such child is free from infection, and unless it has been properly disinfected, shall be liable to a penalty of 40s.

These provisions may be supplemented by regulations made by the sanitary authority, subject to the sanction of the Local Government Board, which regulations may be of any degree of stringency, so long as they do not go beyond the powers here given to them.

Now we do not quote these sections of the Act as suggesting that they are in the least too stringent or unnecessarily burthensome on the house occupier. On the contrary, we hold that the custodian of the patient should be bound down by every possible legal means to perform his duty, however disagreeable, for the safety of his neighbours.

We refer to these sections for the purpose of showing that the physician incurs a very serious responsibility, and must perform a very unpopular duty, if—by the sending of his notification to the sanitary authority—he brings his employer directly within the grasp of these precautionary measures, and we cannot doubt that the fear of all these sanitary procedures would tend to produce an altered condition of things between the physician and his employer, and to make the communication of the physician respecting the nature of the disease less straightforward than it has been, and ought to be.

As to the extension of the system to Dublin, the profession has been afforded by the Irish Medical Association an opportunity of expressing its feeling, and the

whole subject was debated yesterday in the Council of that Association with that expression of feeling before it. The decision of the Association was arrived at too late for record in our pages to-day, but on it depends the question whether or not the Bill is to be actually resisted in Dublin. We shall next week be able to indicate a more decisive policy upon the question.

#### BARRACKS IN RELATION TO HEALTH.

THE subject of barracks has lately been discussed in presence of a distinguished military audience. The principles according to which these buildings are now built are no doubt perfect as compared to those which guided their constructors in former times, yet the facts ought not to be forgotten that in this as in various other matters the advance has been by slow degrees extending over many years, and that even now certain of those principles only being adopted on an extensive scale were suggested by Robert Jackson, the eminent army surgeon, more than eighty years ago, as for example small barrack rooms. He suggested that they should be constructed so as to accommodate twenty-five men each, those now erected accommodate twenty-eight.

Nowhere do we find that soldiers are provided with barracks built upon so large and extensive a scale as in India. These have all, with a very few exceptions, been erected since 1864, and yet already there is reason to doubt whether the results as regards health of this large and costly experiment have been at all equal to expectations regarding it. That such is the case, no doubt arises in some instances from faultiness in site. Thus, at Allahabad, the new palatial barracks were erected upon that of the old ones, the locality known to be unhealthy, so that among the initiated there was no surprise at the occurrence of a violent outbreak of cholera in the first regiment that occupied them. Experience has discovered various sanitary objections in regard to such barracks generally in India. They are believed to be hotter in the hot weather, colder in the cold weather, than the former style of buildings; to be more draughty and generally uncomfortable, more especially in the far interior of that country, where the winds during the cold season are peculiarly *piercing*, also that the occupants of the lower storey have the constant inconvenience arising from traffic in the upper—this inconvenience being in proportion to the thinness of the separating floor; and to the men in the upper stories the difficulty and inconvenience in getting to outhouses, more especially during night time. Some of these inconveniences no doubt admit of being remedied, others do not, but in some stations where the old one-storied and the new two-storied barracks co-exist, the preference of the soldiers is decidedly for the former.

A series of observations as to the comparative temperature in the upper and in the lower rooms of the new barracks gave the following results, namely:—At Peshawar in the month of July, August, and October 1870, the lower stages upon the whole cooler than the upper, the upper room cooler at night than the lower, the new barracks both in their upper and lower rooms slightly cooler at 4 p.m. than the old barracks at the same hour. At Jullundur the upper room was cooler at night than the lower,

but during the day hotter. At Barrackpore in July, August, September, and October, the lower rooms of the new barracks were cooler throughout the whole twenty-four hours than the upper, the temperature in the old barracks sank 2° F. below what it did on either floor of the new, but attained previously the same maximum temperature as in the latter. Thus, as a matter of fact, the diurnal range of temperature in the new barracks is considerably less than what it is in the old—in other words, the new offer better protection against extremes than the old. Nevertheless the general subject remains open, results vary according as to whether the barracks are situated in a dry arid part of India under the influence of the hot winds, or in Lower Bengal, with the peculiarities of soil and climate of that province.

Similar comparisons have been instituted as to the sickness among troops occupying upper and lower stories of Indian barracks respectively. At Lucknow the admissions from lower stories were, exclusive of venereal diseases and accidents, more than double those in the upper, from fever three times, and from bowel complaints in the proportion of 60 to 38 from the upper. From hepatic diseases the order was reversed; of these, 25 cases came from the upper against 23 from the lower, on the other hand, every case of palpitation, debility, and anæmia came from the lower. At Agra, the admissions from all diseases gave the proportion of 1,040 from the lower to 700 from the upper stories, of fevers 920 to 550, bowel complaints 40 to 16, while all hepatic cases came from the upper. At Rawul Pindie, on the contrary, the admissions from all causes were in the proportion of 1,594 from the upper storey to 1,465 from the lower, those by fever 1,316 from the upper against 1,182 from the lower, by bowel complaints 75 to 63, while of hepatic diseases only 12 cases occurred on the upper floor against 22 from the lower; all cases of palpitation, debility, and anæmia were from the lower floor. At Peshawar, the admissions from the upper floor were 3,120 against 1,878 from the lower, of fever 2,846 from the upper against 1,636 from the lower. On the other hand bowel complaints gave 60 admissions from the lower floor to 50 from the upper, palpitation and debility causing in their turn 60 admissions from the lower floor, but also 42 from the upper. At Julundur, in 1869, the troops occupying the double-storied new barracks suffered numerically more from fevers and from other diseases during hottest months of the year than those in the old single storied buildings in the same station. At Soobathoo the admissions by all diseases were 189 from the upper story and 341 from the lower, by fevers 102 against 221, local affections 15 against 25, hepatic diseases 5 against 12, while all the cases of palpitation, debility, and anæmia were from the lower storey. With regard generally to cholera at all Indian stations, the results of observations, so far as they have as yet been made, do not indicate any material difference as to liability to attack or mortality among the occupants of either floor of the double-storied barracks.

ON Saturday last a boiler in the kitchen of the Tiverton Infirmary exploded, killing a boy, and severely injuring one of the nurses.

## Notes on Current Topics.

### London Besieged.

THE intense cold and heavy snow of last week produced in London a state of things, in some respects, such as prevails in a besieged city. Communication with the outside world was cut off—not, indeed, by an investing circle of fire and steel, but by snow-drift, which stopped, and in some instances completely blocked up, railway trains. Street traffic was interrupted, not by falling shells, but by severe frost, and then by heavy snow, rendering it next to impossible for horses to draw carts, waggons, and other conveyances. Few pedestrians ventured upon the thoroughfares—not because they feared a stray shot or ambuscade, but because the biting east wind drove with violence and in eddies little pellets of congealed snow along the streets and round corners everywhere. Houses were quickly reduced to a state bordering upon darkness; cisterns became frozen; thus the water supply, like the gas, was to a great extent cut off. But, worse than all, the food supply speedily showed signs of failure; milk at once became scarce, and enhanced in price; fish and butchers' meat could not be obtained from the coast and country districts; and bakers, unable, similarly, to obtain their flour, expressed their difficulty in meeting demands of their customers. But, worst of all, hundreds of poor and needy people were rendered homeless—not as a result of their houses being torn to pieces by shot and shell, but by inundation of the Thames. Sickness has increased among all classes, but particularly among the lower and poorer orders. Thus, as in a regular siege, so now there is ample room and opportunity for those who are willing and able to render aid to the victims—not of actual war, but of an unusually severe winter, to do so.

### Legislation on London Fogs.

MR. CUBITT has given notice of his intention on an early day, to move for a Select Committee to consider to what extent the fogs of London are injurious to life, health, and property; whether they have increased, and are increasing, from causes which are controllable; whether the existing Acts of Parliament relative to the consumption of smoke are applicable to the present state of the metropolis, and can still be enforced; and whether alteration and extension of this legislation would be beneficial.

### Rewards to Army Surgeons.

In our last we briefly chronicled the fact that Her Majesty the Queen had conferred the Albert medal of the second class on Surgeon Henry Grier, of the Army Medical Department, for the performance of a heroic operation on Lieutenant Graham, who was dying of diphtheria, in the late Afghan campaign. We congratulate Mr. Grier on receiving the distinction justly due to his act of heroism and professional zeal. We trust that the precedent thus established may be liberally followed, and that medical officers of the army and navy may in due time receive, in the proportion they generally earn them, similar recognition for saving life. Hitherto, a wounded artery secured upon a field of battle, a fragment of skull

depressed by shot or shell, and other operations by means of which life has, beyond all question, been saved or prolonged, have received no other reward than the consciousness on the part of the operator of having performed the necessary operations—often under heavy fire and in the turmoil of battle. Already have the members of this department a large proportion of the crosses for valour; to that much-envied decoration is now added the further mark of heroism on their part.

### The Metropolitan Asylums Board.

THE small-pox scare has considerably subsided in London, for which the Arctic weather of the past ten days is probably responsible. There was, therefore, but little business to transact when the Board met on Saturday last, under the presidency of Dr. Brewer. A letter was read from Mr. John Jones, enclosing resolutions passed at a meeting of the inhabitants of Homerton and district deprecating the introduction of small-pox patients into the Fever Hospital there, and further protesting against the erection of huts for the accommodation of the same class of cases. With regard to the negotiations commenced with the view of purchasing the West Ham Hospital for conversion into a hospital for small-pox patients, the Board decided that the project should be abandoned.

### Pot. Iod. in Scarlet Fever.

DR. WATSON, of New Holland, Illinois, writing in the *Monthly Review of Medicine and Pharmacy*, advocates the employment of iodide of potassium in the treatment of scarlet fever, and quotes cases of its successful use in defence of the practice. He prescribes for a child of 7 years tablespoonful doses of a mixture consisting of syr. scillæ, ℥ij., and pot. iod., ℥ss., to be given every three hours. In severe cases he recommends also, in conjunction, quinia and stimulants internally, and a gargle of salt and vinegar; the body to be rubbed with bacon grease. He claims for the iodide that under its use, with due precautions regarding exposure, there are no abscesses to open or dropsical troubles to contend against. Given early in the onset of the disease too, it averts the coming mischief, and the patient easily and rapidly recovers.

### International Medical and Sanitary Exhibition.

A VERY commendable scheme for the holding of an International Medical and Sanitary Exhibition in London, in August 1881, has received an amount of support sufficient to justify the anticipation that it may be successfully carried through. Very appropriately the Parkes' Museum of Hygiene will act in a directing and organising capacity, the Secretary, Mr. Mark H. Judge, being also Secretary to the committee appointed to carry out the exhibition arrangements. The exhibition committee sat on Wednesday last, when it was decided to classify the exhibits under the heads of medical and sanitary. In each section a sub-division into eight classes will be made as follows:—*Medical Section*—1. Surgical instruments and Apparatus. 2. Appliances of the Ward and Sick Room. 3. Drugs, Disinfectants, Medical Dietetic Articles, and Mineral Waters. 4. Electrical Instruments

and Appliances. 5. Microscopes and other Optical Apparatus. 6. Apparatus of other kinds used in the Investigation of Diseases. 7. Appliances used for the Treatment of Sick and Wounded during War. 8. Appliances used in teaching Medicine; Books, Diagrams, Models, &c. *Sanitary Section*—1. Domestic and Hospital Architecture. 2. Planning and Construction. 3. Ventilation, Lighting, and Warming. 4. Water-closets, Sinks, and Baths. 5. Sewerage and Drainage. 6. Water-supply and Filtration. 7. Health Resorts and Sanatoria; Book and Diagrams. 8. Miscellaneous. All inquiries and communications respecting the exhibition should be addressed to the Secretary, Mr. Mark H. Judge, Parkes' Museum of Hygiene, University College, Gower Street.

#### Juridicial Sageness.

AN amusing instance of the ponderous gravity with which the ordinary jurymen of the coroner's court loves to weight his utterances, occurred during the week. A patient who had been run over and brought to Charing Cross Hospital was, after being seen to, permitted to go home, first being asked to remain in the house. He died the next day, and at the inquest several of the jurymen were conspicuously indignant that he was not kept in the hospital, and very freely vented their opinion in the matter of treatment. They considered that the use of the battery which the house-surgeon had applied was improper; and in other ways severely criticised the conduct of the medical officers in the case. The coroner, Mr. St. Clare Bedford, expressed regret that the jury should feel compelled to think the hospital had shown neglect. He might very well have gone further, and shown surprise that a body of jurymen should venture, in the absence of any contra medical evidence to guide them, to call in question the proceedings of the professional gentleman who had attended the case. It is surely within a coroner's duty to repress any such insult as was conveyed, in the absence of justification, by the officious remarks of these jurors. Intelligent criticism and suggestions are admirable in such a case, always; but ignorant abuse is surely out of place in a court of inquiry like the coroner's court.

#### A Deserving Case.

THERE is now depending on the parish of Alford, in Aberdeenshire, an old man, eighty-six years of age, who has possibly done more to deserve the gratitude of the scientific world than many a widely-honoured and richly-rewarded name. John Duncan is an aged country weaver, who, since he was forty years old, has been an assiduous collector of plants indigenous to the soil, from Banff to the shores of Northumberland. During this period he has brought together a rich and valuable herbarium, carefully kept in books; and which now he has given, a free gift, to the use of the students in Aberdeen University. In all, the collection contains 1,131 perfect specimens, and will be of infinite service in the position it now occupies. It is mournful to add that the author of this natural library is in want and overcome by years, and it is to be hoped a liberal response may be made to the appeal on his behalf instituted by Mr. W. Jolly, H.M. Inspector of Schools, Inverness, who will gladly acknowledge donations.

#### The Outbreak of Fever at Tandragee.

WE stated last week that we had reason to know that the severity of the epidemic of typhoid at Tandragee had been greatly exaggerated, and that the idea that it arose from Belgian flax was nonsensical. At a special meeting of the Tandragee Town Council, held on the 14th inst., the following resolution was passed:—"Whilst deeply regretting the existence of typhoid fever in our town, we emphatically condemn the misleading and greatly exaggerated accounts that have appeared in the public prints regarding it, as calculated to cause unnecessary alarm in the minds of those at a distance, and therefore unacquainted with the facts of the case, the truth being, that so far from eleven deaths having occurred in the town in one day, and six in one house, there have been only fifteen deaths from first to last, in or connected with the entire dispensary district, embracing a circuit of some miles. There were only three cases last week; there have been none since, and the disease is fast disappearing, most of the patients being convalescent."

#### The Differences of Doctors.

THE variance of professional judgments upon obscure disease have been quoted by unthinking people as an opprobrium of our art, and people who can't be cured of unknown diseases revenge themselves on their physicians by quoting the proverb that "doctors differ and patients die." But if this sneer be deserved by the professors of an eminent science like medicine what shall be said about the differences amongst lawyers about the mere construction of words and phrases which have been specially put together with an intention that the meaning shall be as clear as possible. One would suppose that upon the sense of such words no question could possibly arise, and yet we find the most ridiculous uncertainty as to their interpretation by the greatest professors of law in the world. For instance, we read that during the year 1880 the House of Lords affirmed 23 decisions and reversed 6. The Court of Appeal, England, decided on appeals from the decisions of Equity Judges, affirmed 51, and reversed 50. In the cases of five judges, whose decisions came up for judgment, it declared 4 of them to have been wrong in a majority of their judgments, and 1 of the 4 was wrong 23 times against 16 times in which his decision was confirmed. Taking the entire bench together, exactly half their decisions were found to be erroneous. Even the bitterest detractors of the doctors will hardly say that half of their diagnoses prove to be wrong.

#### The Dangers of Gymnasiums.

AN inmate of the Philanthropic Farm Schools, at Redhill, recently died from injuries received in the gymnasium attached to the school. In company with other boys deceased had been at play in the place, and was at length pulled to the top of a giant's stride by three of his companions. The latter having their attention momentarily diverted let him go, unthinkingly, and he fell to the ground, receiving such hurt as to cause his death. The coroner's inquiry into the details of the accident was adjourned on Thursday last for further evidence.

### The General Medical Council.

We understand that at a meeting of the executive committee held last week it was decided to call the General Council together on Thursday, February 3rd, "special dental business" being the cause assigned for this early assemblage. The passing of the Dental Act has proved a source of considerable annoyance to the respectable portion of the dental profession, and it is not improbable that proposals will be made for the erasure of a good many names from the Dental Register before the new edition is printed. The Medical Register will, we believe, be ready for publication in a few days.

### Nurses for the Transvaal.

We understand that a lady superintendent and six lady nurses have proceeded from England to the Transvaal with a view of being employed in the military hospitals during the anticipated hostilities against the Dutchmen now in revolt against the English Government. With every desire to be gallant towards the ladies who have thus proceeded upon what they doubtless consider an errand of mercy, the real fact is we are unable to see of what use they can possibly be, or, if they proceed to the actual scene of military operations, that they can be anything else than an encumbrance to the force to which they may be attached, while, as regards themselves, the "roughing" they must undergo, to say nothing of the scenes they must witness, are such as no woman ought to be exposed to. Another little fact is that (if ladies would only believe it) young men, and particularly young soldiers, dislike very much to be attended by them. They much prefer the regular "orderly."

### Accident Traps.

We referred last winter to one of the street dangers of which the gauntlet has to be run by pedestrians in frosty weather, viz., those horrible, shiny, intensely slippery, iron covers to the openings of street coal-cellars. Either in damp weather, or lightly covered with snow, these deceitful contrivances are a certain cause of accident to the unwary. A hundred times worse than a simple slide, they first cause the body to glide onward rapidly, and then, the foot arriving at the side, it is brought sharply up with a jerk, on the violence of which depends the amount of injury sustained by the unfortunate passenger. These slippery contrivances have, during the past week been the cause of many broken limbs, and once more we protest against their use being any longer permitted. It is easy enough to substitute a roughened substance for the material they consist of—a measure imperatively called for in the interests of public safety.

### The Farr Testimonial Fund.

The Executive Committee charged with the promotion of the Farr Testimonial Fund have issued a circular in which they state that they will shortly close the subscription list. The net result of the subscriptions at present paid, or promised, after provision for the necessary expenses of postage and advertising, is not quite £900. It is, however, still hoped that sufficient additional subscriptions may be obtained to raise this sum to a thousand gui-

neas, less than which could scarcely be regarded as a result in any way commensurate with the object in view—a general expression of the exceptional value of Dr. Farr's public services in the cause of sanitary and statistical science. The Executive Committee appeals for further assistance towards supplying the deficiency. The hon. sec. is Mr. Noel A. Humphreys, General Register Office, Somerset House.

### Taraxacum Coffee.

LAST week a grocer was charged with unlawfully selling dandelion coffee, not composed of ingredients in accordance with demand. The borough analyst found that it contained 70 per cent. of chicory and 30 per cent. of an unknown substance, which was neither coffee nor dandelion; on being cross-examined at great length, he was not prepared to say there was no concentrated essence of taraxacum in the preparation, as he had never thought of looking for it. The defendant's lawyer said that the preparation consisted of first-class coffee, chicory, concentrated essence of taraxacum and burnt sugar; and argued that in not putting the dandelion root in itself, but the essence, they were acting in the interests of the public at large, and at a disadvantage of profit to themselves. The magistrates dismissed the case.

### The Domestic Application of the Electric Light.

It would seem that we are not far from the realisation of this dream of the philosophers of the past and hope of the physicists of the future. We learn that the Duke of Northumberland has adopted Swan's electric light at Alwick Castle, and that the library, ante-room, and music room were experimentally lighted, with perfect success. It is stated that Mr. Swan's carbons are made by carbonising slips of vegetable parchment.

This announcement of course, does not mean the economic use of the light for domestic purposes has been achieved, but, at least, it shows that the subdivision of the light has been made practically useful.

### The Contagious Diseases Acts.

ON Monday week last Mr. Childers, on behalf of the government, moved the House of Commons to resume the inquiry into the working of these Acts which was discontinued upon the dissolution of Parliament last year. The committee nominated by Mr. Childers is as follows: Messrs. Massey, Stansfeld, Cavendish Bentinck, Colonel Alexander, Viscount Crichton, Messrs. Burt, O'Shaughnessy, Osborne Morgan, Cobbold, Colonel Burnaby, Sir Drummond Wolff, Mr. Noel, Colonel Digby, Messrs. Fowler and Hopwood, and five others to be nominated by the above committee.

### Kilkenny District Asylum.

DR. CHARLES Lyster, of Kilkenny, has been appointed to the office of Visiting Physician to the Kilkenny District Lunatic Asylum, in the room of Dr. Louis C. Kinchela, who has resigned.

THE president, vice-presidents, and council of the Royal College of Surgeons in England, have issued invitations

for a large party of distinguished visitors to the Hunterian festival to be held on the 14th prox., after the delivery of the biennial oration by Mr. Luke Holden.

MR. G. C. HENDERSON has been appointed as architect to the Royal College of Surgeons in Ireland, in the room of Messrs. Miller and Symes.

THE post of Secretary Superintendent to the Dreadnought Seamen's Hospital, Greenwich, *vice* Mr. H. C. Burdett, who has been elected to a lucrative appointment in the Share and Loan Department of the Stock Exchange, has been conferred on Mr. W. T. Evans.

PROFESSOR SCHAFER gave yesterday, at the Royal Institution of Great Britain, the first of a course of eleven lectures on the Blood. The next Friday evening discourse, at the same Institution, will be given by Dr. Arthur Schuster, on the Teachings of Modern Spectroscopy.

DR. LYON PLAYFAIR has obtained leave in the House of Commons to bring in a Bill to amend the manner of voting in the election of members of Parliament for Scotch Universities. This is in accordance with the threat made, when he was elected to represent the University of Edinburgh at the last general election, by a very narrow majority over Mr. Bickersteth, F.R.C.S.

DR. ILIFF, Medical Officer of Health for Lambeth, has been entering an earnest protest against the exercise of the power which the water companies possess of cutting off supplies either because rates are in arrears, or because proper fittings are not provided. As he rightly observes, the practice, although legal, is fraught with the gravest consequences to the health of those immediately concerned.

SURGEON-MAJOR FOX, of the Madras Medical Service, has been selected by Mr. Adam, the new governor of that Presidency, to be surgeon on the personal staff of His Excellency. His Grace the Duke of Buckingham had on his staff successively two surgeons of the Army Medical Department; it is, therefore, fair that the appointment be now given to the local service. Of Surgeon-Major Fox we are happy to learn that his professional reputation is of the very highest order.

INSTRUCTIONS have been received by the Principal Medical Officer of the Aldershot Division from the Director-General, Army Medical Department, that all recruits should be subjected to special supervision and examination by medical officers for a period of three months after their enlistment. Commanding officers are requested to afford the necessary assistance to medical officers to enable them to carry out their duties in this respect.

THE rates of mortality last week in the large towns of the United Kingdom were—Brighton 13, Newcastle-on-Tyne 16, Portsmouth 16, Hull 19, Bradford 20, Leicester 21, Wolverhampton 21, Sheffield 22, Birmingham 22, London 22, Leeds 22, Edinburgh 23, Plymouth 23, Norwich 24, Glasgow 24, Bristol 25, Nottingham 25, Sunderland 26, Liverpool 29, Salford 30, Manchester 32, and Oldham 33 per 1,000 of the population.

IN the principal large towns last week scarlet fever showed the largest proportional fatality in Oldham, Norwich, and Bristol; measles in Salford and Brighton; and whooping-cough in Nottingham and Leeds. The death-rate from fever (principally enteric) showed a further decline from that prevailing in recent weeks—Glasgow and Liverpool giving the highest average. Of the deaths referred to diphtheria 12 occurred in London. Small-pox caused 28 more deaths in London and its Outer Ring of suburban districts, whereas no fatal case was recorded in any of the provincial towns.

THE president of the King and Queen's College of Physicians in Ireland—Dr. George Johnston—entertained the Fellows and officers of the College and a number of the leading members of the profession in Dublin, at an official dinner in the College on Wednesday the 19th. Amongst the guests present were the president of the Royal College of Surgeons; the physicians, surgeons, and ophthalmic surgeons to Her Majesty and the Lord Lieutenant; the medical commissioner of the Local Government; the judge of the Admiralty Court; and many other officials and heads of departments connected with the profession. In the intervals between the toasts a number of glees and solos were performed by a party of musical artists. The entertainment was brilliant and eminently successful.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

GLASGOW TRAINING HOME FOR NURSES.—The Seventh Annual Meeting of the Glasgow Training Home for Nurses was held in the Christian Institute, Glasgow, on the 18th inst, Mr. J. White, of Overtoun, in the chair. Mr. Cuthbert, honorary secretary, read the annual report, which stated that the Glasgow Training Home for Nurses continues to make satisfactory progress. During the past year 159 patients were treated at the Home, of whom 93 underwent operations of more or less severity. After longer or shorter periods of treatment 105 of the patients left cured of their ailments, 18 were relieved, 23 improved, and 1 died. The number of patients in the Home at 31st December was 13. Although none of the patients suffered from infectious disorders, their ailments were of such a varied character as to afford good opportunity for practical training in the art of medical and surgical nursing. The directors have received the most gratifying assurances of the great advantages conferred by the private hospital department of the institution. Their only regret is that the accommodation for the reception of patients able and willing to pay for it is so limited. During the past year trained nurses were sent out to wait upon 233 cases of sickness in private families; and the reports received both from the medical profession and from the patients and their friends, in regard to the fidelity and efficiency of the nurses, are most satisfactory.

OUTBREAK OF FEVER AT ROSENEATH AND CLYNDER.—A serious outbreak of scarlet fever has taken place at Roseneath, which is causing much anxiety to every one connected with the parish and neighbourhood. The disease has been prevalent in Greenock and Helensburgh for some time, but

it was hoped that the opposite shore might escape. This has not, however, been the case, and the infection has broken out in a most virulent form, chiefly in Roseneath and Clynder, though it appears to be extending along the shores of the loch. Fortunately most of the cases are mild, but two deaths are as yet reported. Discussion has lately been rife on the necessity for a more complete system for getting rid of the sewage of the various localities around the Gareloch, and we trust a fresh impetus may be given to the inquiry by this disastrous epidemic. If the present unsavoury condition of many portions of the shore is allowed to continue nothing can be looked for but the repeated outbreaks of fever and other epidemic diseases that have already occurred. Dr. Yair is at present investigating the causes likely to have led to the present unfortunate state of matters, and is directing his particular attention to the drainage of the infected districts.

**DEATH OF A CHILD FROM DRINKING VITRIOL.**—A child has died in Dundee from accidentally drinking vitriol. On the 19th inst. the wife of Thomas Brown, fisher, gave what she supposed to be an empty bottle to her son Thomas, a boy about one year and nine months old, to amuse himself with. The bottle, however, seems to have contained a small quantity of vitriol, which the child, unobserved by its parents, drank. In a few seconds he began to suffer great pain, and the parents, ascertaining what had taken place, sent immediately for Dr. Gray, who was soon in attendance. The boy lingered in great agony until the 21st.

**THE LATE MR. JOHN CROOKS MORISON, DENTAL SURGEON.**—We regret to have to record the death of this young and esteemed surgeon-dentist. The cause of death was a virulent attack of typhoid fever which carried him off in a few days. After qualifying himself with considerable success, under the best authorities at the Royal College of Surgeons, London, as a licentiate in dental surgery, Mr. Morison came to Glasgow, his native place, and took over the business begun by his relative, the late Mr. Croods. The business was rapidly developing into one of the best practices in Scotland. With a few other gentlemen in the same department of practice he originated and was one of the lecturers in connection with the Dental College of Glasgow, the first of the kind in Scotland. Mr. Morison was the elder son of the Rev. Dr. Walter Morison, of London, and formerly of Glasgow.

**IMPORTANT MEDICAL APPOINTMENT.**—We understand that Dr. W. J. Fleming has been appointed President of the Glasgow Medical Smoking Club, a position, no one will dispute, which he is eminently qualified to adorn.

**A POKER BY A SCOTCH PROFESSOR.**—The following *difficult* problem was recently propounded to a class:—"What are the contents of the human stomach when it is empty?"

**HEALTH OF EDINBURGH.**—For the week ending with Saturday, the 15th inst., 97 deaths occurred in Edinburgh, and the rate per 1,000 was 23. Chest diseases accounted for, at least, 50 deaths, and scarlatina for 4, 3 of which occurred in the New Town and 1 in the Old. The northern suburbs were entirely free from zymotic deaths.

## Literature.

### AN ELEMENTARY TREATISE ON THE FUNCTION OF VISION AND ITS ANOMALIES. (a)

The next and handy volume before us, on the "Function of Vision and its Anomalies," although professedly a trans-

lation of a larger work by Giraud-Teulon, is a praiseworthy and earnest endeavour to give, in an English dress, the pith of a work, not sufficiently well known, even amongst specialists. The principles of modern ophthalmology are placed before the student and general practitioner, concisely and explicitly, by one who is evidently in perfect accord with the teaching of a master of the science, and who desired to render the principles of the more abstruse portions of modern ophthalmology more easily acceptable to those amongst his professional brethren, whose time is almost wholly engrossed in other branches of medical practice; but who desire, with all earnestness, to master the physical and mathematical niceties, which later investigations of the functions of vision seem to involve. It is quite as much the duty of the physician, as the ophthalmologist, to become acquainted with the anomalies and disturbances of vision, as without it certain functional disorders will hardly be discriminated and fairly diagnosed. This is even more essential since, in a large number of cases of eye disease, the physician's opinion is first sought, and upon his diagnosis very frequently hangs the welfare of the patient. Having said thus much we proceed to indicate the principal contents of the treatise, and which, for the sake of easy reference, is divided into several chapters. The first deals with the eye as an optical instrument. Its several physical conditions are then explained, as well as the function of images, and the mode of judging of proportions, and the faculty of accommodation or adaptation, together with binocularity. In chapter ii., we pass on to the consideration of the physiological influence of age in the production of many anomalies of vision, an abridged symptomatology, together with general indications for treatment, are lucidly set forth. As a specimen of Mr. Lloyd Owen's lucidity of style, and as enforcing the views of the author on the attention of the general practitioner, we quote the following:—

"The characteristic symptoms of accommodative asthenopia (hypermetropia), should be present in the mind of every practitioner of medicine; this affection is one of the most frequent which presents itself in the study of diseases of the eye; in the statistics of special clinics it occupies the fifth or sixth place in point of frequency. The practitioner should, however, be on his guard with respect to a deceptive appearance: it sometimes happens, either from the effect of spasm of the overstrained accommodation, or from a true consecutive amblyopia, that the hypermetropes presents, with the semblance of the opposite condition, myopia, phenomena due to two varieties of causes. In a high degree of hypermetropia, the long accommodative efforts, by congesting the deep membranes, frequently induce a certain degree of amblyopia, and the patient no longer seeks clearly defined images, and these are obtained by an increased approximation of objects, by means of which the retinal pictures enlarge much more rapidly than the circles of diffusion."

We demur to much that has lately been written and said upon the greater frequency of myopia amongst students, and the influences of school-life in its production. The statistics, however, compiled from the examination of a large number of scholars and students, the author tells us, show "that myopes are found in all schools; that whilst relatively few in village schools (1.4 per cent.), they are eight times more numerous in town schools (11.4 per cent.) That in the town schools the proportion of myopes increases with the standard of the schools, and that in all the schools of whatever kind, the upper classes contain more myopes than the lower."

The degree of myopia, we are also told, increases "in proportion with the standard of the school," and is believed to be owing chiefly to the close application of sight to near objects. "Among secondary causes, must be cited, insufficient illumination, bad print, pale ink, and very small type, antecedent amblyopia; in a word, all the conditions which impel the scholar to seek a larger retinal image by the approximation of the object." With a no inconsiderable experience we cannot say we agree with all the conclusions arrived at on the continent; nevertheless, we are quite of opinion that the consideration of the question is one of the highest importance for the future of the young, and calling

(a) "An Elementary Treatise on the Function of Vision and its Anomalies." Translated from the Second French Edition of Dr. Giraud-Teulon. By Lloyd Owen, F.R.C.S.I., &c, London; Baillière, Tindall, and Cox. 1880.

for the greatest solicitude, not only on the part of families and the medical practitioner, but likewise of departments of public health.

We can very conscientiously commend this manual for "its simplicity of arrangement, unimpeachable accuracy, and marked conciseness" to those who would become acquainted with the functions and anomalies of vision, as laid down in bulkier and far more expensive treatises on the subject.

### THE LONDON HOSPITAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—For some time rumours have been in circulation that dissensions had arisen between the committee and the staff of the London Hospital; and that in consequence of the pretensions of the nursing department and the meddling of religious zealots the efficacy of the charity and the independence of its civil officers were alike in peril.

At first these rumours were considered by us to be unworthy of notice; but now that they have taken definite form, have been permitted to appear in the public journals, have caused pain to many persons, and are influencing public opinion, it seems necessary that the truth should be made authoritatively known.

Permit us, therefore, to declare that all these rumours are wholly groundless; that the relations of the executive to the staff, and of the nursing department to both were never more complete and harmonious; and that at no former period of our history has the committee given us more liberal, enlightened, and salutary assistance in our practical and educational work.

We are, Sir,

Yours, &c.,

ANDREW CLARK, M.D., Senior Physician,  
JONATHAN HUTCHINSON, Senior Surgeon,  
T. TIBART SMITH, M.D., Hon. Secretary  
to the Medical Council.

19th January, 1881.

### DRUG CONTRACTS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I am glad to see by a recent issue that an effort is being made by some members of the medical profession in Dublin to put an end to the present system of supplying drugs to the workhouses and dispensaries in Ireland. It is high time to do something in the matter, as the way in which contracts for medicine are now given is simply ridiculous. I append a few of the prices at which the contractor to the union in which I hold a workhouse and dispensary appointment, has agreed to supply the best medicines; and by way of comparison I have taken the market value from the trade list of a respectable house:—

	Contract Price.		Market Value.	
	s.	d.	s.	d.
Acid sulph. aromat.	...	1 6	3	6
Spts. æther ol. (Hoffman)	...	0 10	4	0
Spts. æther nit.	...	1 0	3	2
Spta. ammon. aromat.	...	1 0	3	0
Tinc. cinch. co.	...	1 10	3	4
Pil. colocynth co.	...	3 0	13	0
Ferri et quinia citrate	...	10 0	40	0
Tinc. lobelia ætheral	...	1 10	6	6
Tinc. opium	...	2 6	4	6
Tinc. guaiacum ammon.	...	1 9	3	6

£1 5 3      £4 4 6

What is to become of the patients to whom such medicine is given?

I am, sir, yours truly,

A WORKHOUSE DISPENSARY DOCTOR.

## Novelties.

### MEDICATED THROAT PASTILLES.

(ALLEN AND HANBURY'S.)

WE have employed with much satisfaction and can therefore recommend with great confidence these agreeable and efficacious remedies. They are free from the defects of the lozenges in common use, for which they may be advantageously substituted, and they possess certain positive merits of their own. They are prepared from formulae furnished by Dr. Prosser James, who described them in a paper presented to the British Medical Association at Cambridge, where they were also exhibited by Messrs. Allen and Hanburys, the manufacturers. The qualities proper for medicated lozenges, as laid down in the paper mentioned, are all possessed by these pastilles which will, we doubt not, be extensively prescribed in affections of the throat and bronchial tubes. Some of them are used for their general, others for their topical effects, and others perhaps mostly for both. In order to bring them before our readers we shall take first those which may be regarded merely as pleasant substitutes for the lozenges of the Pharmacopœia. They are—1, *Pastilli morphiae*; 2, *pastil. ipecac.*; 3, *pastil. morph. et ipecac.*; 4, *pastil. opii et bell.* (equivalent to *troch. opii* with the addition of *belladonna*); 5, *pastil. ferri*; 6, *pastil. potass. chlor.* All these may be prescribed in the same manner as the similarly named *trochisci*, and they will in almost all cases be preferred by patients, especially children, who will take them as sweetmeats. The chlorate of potash pastille is a remarkable success, its nauseous flavour being completely disguised. It is not so strong as the B. P. lozenge, and may therefore be taken in double quantity, if need be. We may add a few words as to the specimens before us which have no corresponding lozenge in the Pharmacopœia.

1. *Pastilli aconiti.*—This drug was strongly recommended and the lozenge form indicated as often of special use in Dr. Prosser James's early writings. Accordingly, various lozenges have long been in use made from his prescriptions, but the present will probably, from its agreeable flavour and appearance, displace all its predecessors. Half a drop of B. P. tincture is contained in each pastille.

2. *Pastil. soda chloratis.*—This substitute for the chlorate of potash pastille lozenge, is prepared with the analogous soda salt, and often used by Dr. James.

3. *Pastil. lithic.*—Each contains one grain. An agreeable method of taking this alkali. Perhaps this pastille may be also regarded as a substitute for the B. P. soda lozenge.

4. *Pastil. benzoati.*—This is a mild but efficacious voice lozenge, agreeable to take, containing benzoic acid and flavoured with aniseed. It is of a very delicate green colour, quite *sui generis* among lozenges.

5. *Pastil. camphora comp.*—These are a stronger voice lozenge of a warm aromatic taste, but the flavour of the camphor is so pronounced that it will not be liked by some. It is the least agreeable of the series, but we have found it very valuable in several cases, in fact a better voice lozenge than any in the market, and also very useful in follicular sore throat.

6. *Pastil. morph. et ipec. comp.*—This contains squill, &c., in addition to the ipec. and morph. which are present in nearly the same amount as in the simple one. It will be extremely useful in chronic bronchial catarrh, and may be tried as a good cough lozenge, whenever such a remedy is required to be placed in the patients' hands.

We have described these pastilles thus fully because we are sure our readers will find them useful additions to their materia medica, and we think them a distinct advance in elegant pharmacy. Allen and Hanburys have produced them at a very moderate price.

### TEMPORARY HOSPITALS IN EPIDEMICS.

Now that London is threatened with another visitation of small-pox, the attention of the authorities might with advantage be drawn to the facility which the erection of hospital marquees affords for isolating cases of infectious diseases. Some time since we saw one which had been erected for this purpose by Messrs. Edgington & Co., of Smithfield, in full operation. To outward appearance it looked like an officer's mess tent. Inside it was lined to keep out the cold,

whilst a temporary wooden floor, six inches from the ground, served to prevent the dampness from rising, and to act as surface drainage. The ventilation was perfect, and every accommodation was provided for the comfort of the patients, and the convenience of doctors and nurses. The great advantages of these temporary structures is, that they are comparatively inexpensive; they can be put up in twenty-four hours in any open spot, and taken away equally quickly when the necessity for them has passed,

**THE LADIES' SANITARY TOWEL.**

MESSES. SOUTHALL, of Birmingham, have introduced a ladies' sanitary towel for use during the catamenial period, in place of the ordinary napkin. They are admirably adapted for the purpose they serve by virtue of their softness and antiseptic properties. We have received abundant testimony to their excellence, it being said of them that their slightly increased bulk makes them for a short time uncomfortable to wear, but this being got over, they are infinitely preferable to the hitherto universally employed napkin. The disagreeable chafing of the latter is entirely avoided, and the cost of the new towels is no more, in comparison. They are readily destroyed after use by burning, and in every way they are a vast improvement on ordinary appliances. In matters which do not pertain to fashion, ladies are generally averse to change, but if they will take the hint in this particular, we promise them it will redound very much to their comfort.

**TONGA.**

This remedy has proved effective in all those cases of facial neuralgia in which we have prescribed it; one of persistent acute attack having been markedly and quickly relieved by its use. Its action would seem to be chiefly confined to the fifth nerve, affections of other nerves being less influenced for good. It may with confidence, however, be given in the former description of case, and in the form in which it may be obtained from Messrs. Allen and Hanbury, it is an elegant and easily taken remedy.

**FRY'S MALTED COCOA.**

THE need of a palatable, unadulterated cocoa for the use of invalids and delicate persons, is often experienced by practitioners. Messrs. J. S. Fry and Sons' preparation of "malted cocoa," answers for an admirable degree this requirement, and to all who approve cocoa as a beverage, nothing of the kind more nutritious or more pleasant can be recommended. The flavour conferred by the extract of malt in combination is peculiarly agreeable, and adds tonic properties that highly increase the value of the compound.

**GINGER CHAMPAGNE.**

MR. HAY is now so well known throughout the profession and amongst manufacturing chemists as the discoverer of a method of producing a perfectly pure and transparent essence of ginger that any novelty coming from him deserves attention. Keeping pace with the wholesome demand for non-alcoholic beverages, he has introduced a "Ginger Champagne," which, to our minds, will take rank as one of the most delicate and wholesome of this class of drinks at present in the market. The creaminess, colour, and even the aroma of champagne are precisely imitated, and the after-flavour of the ginger essence is peculiarly grateful at this inclement season.

**Medical News.**

Royal College of Surgeons of England.—The following candidates having passed the required examination for the diploma, received the diploma of M.R.C.S. at a meeting of the Court of Examiners on January 18th:—

- Carter, D'Arcy Bainbridge, Leeds.
- Clarke, Walter James, Birmingham.
- Evans, Thomas Jones, Llanbyther, Carmarthen.
- Holt, William, Camberwell New Road.
- Hooley, Arthur, L.R.C.P. Edin., Cobham.
- Houghton, F. E. Caulfield, Dudley.
- Jones, Robert Langford, L.S.A., Bangor.
- Lloyd, William, Gt. Harwood.
- Matthews, Samuel Richard, Llandinabo.

- Oates, John Harrison, Dewsbury.
- Poett, Patrick Matthias, L.K. & Q.C.P.I., Teremire, Dublin.
- Prendergast, Joseph Moran, L.S.A., Melbourne, Australia.
- Sellers, William, M.D., Radcliffe, Manchester.
- Sharples, William Henry, Preston.
- Stanwell, William, Rochdale.

The following passed on Wednesday, January 19th:—

- Bell, William Taylor, Totterdean Park.
- Bond, Richard Pratt, L.R.C.P. Edin., Cheltenham.
- Brown Percy, L.S.A., Camberwell.
- Chronnell, James, Manchester.
- Field, C. A. E. Adolphus, Camden Road.
- Gardner, James Clark, Newcastle-on-Tyne.
- Lidiard, Sydney Robert, Dulwich Road.
- Marshall, James, Plymouth.
- Puddicombe, Francis Moran, Dartmouth.
- Roberts, Frank Ernest, Lower Norwood.
- Shepherd, T. A. Jordan, L.S.A., Rotherhithe.
- Voisain, Alexander Bishop, Jersey.

Liverpool Medical Institution.—At the annual meeting on Tuesday, Jan. 11th, the following officers and council were elected for the ensuing year:—*President*: Mr. Reginald Harrison. *Vice-Presidents*: Dr. Caton, Dr. Dickinson, Dr. Gee, and Mr. Townson. *Hon. Treasurer*: Dr. W. M. Campbell. *Hon. General Secretary*: Mr. Rushton Parker. *Hon. Secretary, Ordinary Meetings*: Mr. E. A. Browne. *Hon. Librarian*: Dr. Howe. *Council*: Dr. Barr, Mr. Banks, Mr. McCheane, Mr. Ransford, Dr. Rawdon, Dr. Waters, Dr. Burton, Dr. Costine, Dr. Cregeen, Dr. Hicks, Dr. Hoppey, and Mr. Paul. *Microscopical Committee*: Dr. Alexander, Dr. Braidwood, Dr. Briggs, Dr. Glynne, Dr. Grossmann, Dr. Hicks, Mr. Newton, Mr. Rushton Parker, Mr. Paul, and Dr. W. Williams.

**RETENTION OF URINE COMPLICATING PREGNANCY.**

A CASE in the practice of Dr. Canvy, of Beziers, was brought before the Paris Société de Chirurgie, Dec. 29 (*Le Praticien*). A woman in the third month of pregnancy showed a swelling of the abdomen which would seem to indicate a more advanced period. One physician she consulted indeed thought so, but really there was retention of urine due to vesical tenesmus. Dr. Canvy, for a month, had to employ catheterism daily. It is probable that the trouble had its origin in a uterine retroversion compressing the neck of the bladder. Practitioners would do well to be on their guard against similar cases.

**NOTICES TO CORRESPONDENTS.**

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 36 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The usual quarterly court of the Directors of the above Society was held on Wednesday, Jan. 12, at 5 p.m., Mr. John Gregory Forbes, V.P., in the chair. A sum of £1,270 was awarded to 59 widows, 15 orphans, and 3 recipients of relief from the Copeland Fund. The expenses of the quarter were 268 2s. 6d. There were no fresh applicants for ordinary grants, and one only for extra relief from the Copeland Fund. Two new members were elected, and the death of one was announced.

**QUALIFICATION FOR DISPENSARY LOCUM TENENS.**

To the Editor of the MEDICAL PRESS AND CIRCULAR,

SIR,—You will oblige me very much by informing me in your next issue "if a person can, with one qualification (i.e., surgeon or physician), hold the office of locum tenens in a dispensary district?"

Yours obediently,  
L.R.C.S.I.

[No, except by special permission of the Local Government Board, which, however, might be granted under exceptional circumstances. See regulations, Article 20, "Irish Med. Directory," page 250.—Ed.]

PROF. NEVINS HYDE, Chicago, is thanked for his courteous letter of the 2nd January, and the two pamphlets accompanying it. We shall endeavour to continue to merit the grateful appreciation of our Transatlantic correspondents.

DR. OGILVIE WILL, Aberdeen, will please accept our thanks.

LAST WEEK'S WEEKS.—There were 13½ British and foreign wrecks, of which 100 were British, reported during the past week, making a total of 225 for the present year, or an increase of 128 as compared with the corresponding period of last year. The approximate value of property lost was £12,000,000, including British £9,800,000. One hundred and eight vessels were lost off the coasts of the United Kingdom. Such a destruction of life and property has never before been registered in so short a space of time.

#### THE CIVIL SERVICE RATE OF SUPERANNUATION.

To the Editor of the Medical Press and Circular.

SIR,—In one of your leaders of yesterday's date there is the word "one-sixth"—in the circular of the English Local Government Board of last week "sixtenths," and in something I read lately about the Civil Service there is the word "one-sixtieth," and which are all probably intended to mean the same thing. Would you be pleased to say which is the proper word to be used, and give a case as an example in your next, and oblige,

Yours truly,

R. C.

[The Civil Service rate is one-sixtieth for each year of service—i.e., if an officer has served 20 years he is entitled to twenty-sixtieths, otherwise one-third of his salary and emoluments.—Ed.]

DR. T. M. D.—Letter approved and sent to the gentlemen concerned. The communication for our columns shall appear as soon as space permits.

LE DR. BOURNEVILLE, Paris, is thanked for his courtesy.

DR. NORMAN KEER.—We regret our inability to have inserted your paper owing to great pressure upon our space. We hope to find space for it during next month.

REFRACTORY PAUPERS.—A correspondent writes us that an outbreak occurred on Saturday amongst the paupers at the Alderbury Union Workhouse, near Salisbury. A number of able-bodied men broke out of the house and got drunk. On their return they broke nearly 700 panes of glass, and smashed bedsteads and other articles. Beds and bed-clothing were thrown into the yard, and a valuable St. Bernard dog belonging to the master was so injured by a spade that it had to be killed. Seven of the rioters are in custody.

#### TOFFEE.

To the Editor of the Medical Press and Circular.

SIR,—Co'd wintry weather recalls visions of one of the great solaces of our youth, namely, "toffee." We hear little of it now; yet it held an honoured position up to a recent period. We used to think "toffee" the sweet of all others, either when we had a cold or the weather was severe. It was a pleasure to buy it; but our delight was at its height when the big brass preserving pan was got out and a liberal quantity of butter and sugar found its way into it. Treacle was not despised nor despicable. How well I remember our impatience while the mass boiled, the cups full of cold water put forward at brief intervals for a spoonful of the boiling fluid in order to test how it got on. The obagrin while it still diffused itself through the water; the boisterous joy when it turned firm. Then to see it poured into moulds to cool; or a certain portion, after partial cooling, taken into hands covered with flour and pulled into sticks, and then twisted or wreathed into knots. And then the eating of it while we ran or slid on the frozen ponds and icy roadways rendered almost unfit for travel by the "slides" established upon them. The rural police have probably been responsible for the repression of the latter; but surely they have not abolished "toffee." That delectable sweet, however, has some how gone out of fashion. Yet it was a grand mixture of hydrocarbon! Sugar and butter, the latter such a digestible fat. How cold children, or even those of riper years, possibly have a more digestible hydrocarbon, with greater heating property, than "toffee" for cold weather! It is not nearly so destructive to the teeth as the acid sweets. In fact, it may be asserted that "toffee" belonged to times when dental caries was almost unknown. Doubtless, the sticky mass can produce toothache when greedily chewed; but that is not a sufficient reason for its present disfavour. It is old-fashioned and antiquated as compared with the modern cheap sugar sweets; but for heat-giving power they cannot compare with it in cold weather. Why then, should not "toffee" take its place once more?

Yours faithfully,

AN OLD-FASHIONED M.D.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.—Wednesday, Jan. 28, at 8.30 p.m., Annual General Meeting.—Mr. W. A. N. Cattlin, "On the Imperfections of the Dentists Act, with suggestions as to the Alterations required to protect the interests of qualified Surgeons."

HUNTERIAN SOCIETY.—Wednesday, Jan. 26, at 8 p.m., Mr. Waren Tay, "On a Case of Colotomy."—Mr. Gilbert, "Notes on Cases in General Practice."

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—Wednesday, Jan. 24, at 8 p.m., Mr. Edmund Johnson, "On Five Years' Experience of the Working of the Trade Marks Registration Act."

ROYAL INSTITUTION.—Friday, Jan. 29, at 9 p.m., Dr. Schnater, "On Modern Spectroscopy."

QUEKETT MICROSCOPICAL CLUB.—Friday, Jan. 29, at 8 p.m., Mr. B. W. Priest, "On Sponges."—Dr. T. S. Cobbold, "On Filariæ."

CLINICAL SOCIETY OF LONDON.—Friday, Jan. 29, at 8.30 p.m., Dr. Sutherland, "On a Case of Chronic Vomiting, in which no food except Koumiss was taken for sixteen months."—Mr. Hulke, "On the Results of a Trial of Chian Turpentine as a Reputed Remedy for Cancer of the Female Genital Organs, conducted during several months of 1880 in Whitbread Ward, Middlesex Hospital."—Mr. J. W. T. Sale (Scarborough), "On a Case of Quiescent Scirrhus."—Mr. Heath, "On a Case of Gangrene of the Arm from a Poisoned Wound; Amputation at the Shoulder, and Recovery."—Dr. Whigham, "On a small Round-celled Sarcoma of the Dura Mater encroaching on the Left Temporo-sphenoidal Lobe of the Brain, and producing Extensive Softening in its neighbourhood; Absence of Aphasia, the Patient being Left-handed."

THE DUBLIN OBSTETRICAL SOCIETY will meet on Saturday, Feb. 4, at 8 o'clock, at the Royal College of Physicians, when the following communications are set down for reading: The President, "On Uterine Polyp."—Dr. Macan, "On Antiseptics in Obstetrics."

THE PHARMACEUTICAL SOCIETY OF ENGLAND.—The next evening meeting will be held on Feb. 3, at 8.30, when the following paper will be read: "On the Weights, Balances, and Measures employed in Pharmacy, the errors which are liable to occur in using them, and means by which the accuracy required in the weighing and measuring of medicines may be promoted," by Prof. Redwood.

HARVEIAN SOCIETY OF LONDON.—Monday, Feb. 3, at 8.30, "A Case of Temporary Hemiplegia after Localised Convulsion," by Dr. Hughlings Jackson.—Paper: "Types of Imbecility," by Dr. Fletcher Beach.

#### VACANCIES.

Baillinrobe Dispensary.—Medical Officer. Salary, £125. Election, Feb. 10.

Bromyard Union.—Medical Officer for No. 1 District. Salary, £120, with the usual extra fees. Applications to the Clerk of the Union before Feb. 6.

Carney, No. 2 Dispensary.—Medical Officer. Salary, £120. Election, Feb. 2.

Devon and Exeter Hospital.—House Surgeon. Salary, £180, with board. Immediate applications to the Secretary at the Hospital, Exeter.

Richhill Dispensary.—Medical Officer. Salary, £140. Election, Jan. 31.

Richmond District Lunatic Asylum.—Assistant Medical Superintendent. Salary, £180, with other allowances valued at £84 per annum. (See Advt.)

Royston Union.—Medical Officer of Health. Salary, £100. Applications to the Clerk of the Guardians before Feb. 8.

Three Counties Asylum, Arlesey, Beds.—Assistant Medical Officer. Salary, £100, with board. Applications to the Medical Superintendent.

#### APPOINTMENTS.

CARSON, H., M.R.C.S.E., Medical Officer to the Stapleford District of the Wilton Union.

CUMMINGHAM, A., M.B., C.M., Medical Officer of Health for the Oldbury Urban Sanitary District.

FARRAR, C., L.F.P.S.G., Medical Officer to the Fourth District of the North Wiltshire Union.

FURSVALL, C. H., M.B.C.S.E., Medical Officer of Health for the District of Acton.

HOOPER, A., M.R.C.S.F., Medical Officer of the Burton-on-Trent District and Workhouse of the Burton-on-Trent Union.

KAY, T. V., L.R.C.P. Ed., L.R. S. Ed., Medical Officer to the Clay Cross District of the Chesterfield Union.

MILLES, W. J., L.R.C.P.L., M.R.C.S.E., House Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

OGILVIE, L., M.B., B.Sc., Extra Physician to the North West London Free Dispensary for Sick Children.

#### Births.

BERNARD.—Jan. 19, at Queen's Road, Upton Park, E., the wife of A. G. Bernard, M.R.C.S., of a daughter.

BODY.—Jan. 13, at Crediton, Devon, the wife of H. M. Body, M.R.C.S., of a daughter.

MYRTLE.—Jan. 19, at Hart gate, the wife of Dr. Myrtle, of a son.

SANKEY.—Jan. 14, at Sandycroft Park, Gloucestershire, the wife of W. A. C. O. Sankey, L.R.C.P. Ed., of a son.

#### Marriages.

SPARKS—GREEN.—Jan. 18, at Capel, Surrey, Alfred Sparks, of Broadstairs, Ramsgate, to Edith Ellen, fourth daughter of Wm. Abbott Green, M.R.C.P. Lond., Principal Inspector-General of Hospitals, Bengal (retired).

#### Deaths.

CRUCKNELL.—Jan. 14, at Epsom, after a long illness, H. H. Crucknell, M.D., Fellow of Oriel, Oxford, aged 50.

HARLAND.—Jan. 20, at Tunbridge Wells, Sarah Frances Julia, wife of Henry Harland, M.D., aged 45.

IRONSIDE.—Jan. 16, at Edinburgh, Surgeon-Major Wm. Ironside, M.D., Army Medical Department.

KEER.—Jan. 19, suddenly, William Kerr, L.R.C.P. Ed., L.F.P.S.G., of 59 Vauxhall Walk, Lambeth, S.E., aged 37.

MOORE.—Jan. 17, at his residence, 8 Queen Street, Lancaster, J. Daniel Moore, M.D., after a lingering illness, aged 64.

MYRTLE.—Jan. 18, at Harrigate, William Ernest, fourth son of Dr. Myrtle, aged 13.

### THE CATGUT LIGATURE. (a)

By JOSEPH LISTER, D.C.L. Oxon., LL.D. Cantab., F.R.C.S., F.R.S., &c.;

Professor of Clinical Surgery in King's College; Surgeon to King's College Hospital; President of the Clinical Society of London.

It was originally feared that the catgut ligature would not be found suitable in every case, and occasional accidents following its use justified the gradual disfavour it encountered. Prof. Lister, however, could now use it with safety in all cases, and he trusted that his experience might affect the practice of those surgeons who, disappointed with catgut, were returning again to silk as a ligature. Some time ago he himself, while operating on the thyroid body, found himself without an animal ligature of strength sufficient for the purpose in hand, and employed in place, hemp—previously made antiseptic. For eight or nine days after, the wound pursued a regular antiseptic course; at the end of a month one ligature escaped; six days later four more came away. When examined they were found to possess a sour odour, and acid reaction, thus showing that a fermentation of a peculiar kind had been going on in the wound. The microscope revealed a special minute organism in the meshes of the hemp, to which the term *granuligera* had been applied. Mr. Cheyne has since proved that this fermentation is of common occurrence, and in no way interrupts the antiseptic progress of the wound. The influence exercised by the fermentative material was shown by the turbid condition of a bottle of water, into which, four days previously, a small portion of blood clot from a wound had been in-

(a) Abstract of the Presidential Address delivered before the Clinical Society of London, Friday, January 28th, 1881.

duced. Mischief may be set up by the organisms in spite of their usually harmless presence. In the case referred to the patient was discharged with a small sinus; and last September the remaining hempen ligature came away unaltered. Ligatures made from the fibrous elastic coat of the aorta of large animals, have been introduced by Mr. Barlow, but they are not so reliable as good catgut. The latter, too, is cheap, being obtainable at a penny a hank; but in the condition in which it leaves the manufacturer it is unfit for the surgeon's use, by reason of the ready manner in which it is softened and altered by blood serum, the knots on it then at once yielding. When properly prepared, however, and previously tested in blood, good catgut is pre-eminently the best material for ligaturing arteries in continuity. Prof. Lister narrated the details of nine cases in which he had so employed it. In one, a young woman, the carotid was successfully tied, but now—six years after—the pulsating tumour, on account of which the operation was performed, still exists. The wound, however, healed entirely without suppuration. In six of the cases the operation of tying the femoral was resorted to for popliteal aneurism, four being in no way remarkable. One was a large arterial venous aneurism in the thigh, of such special interest that Mr. Lister promised to bring it *in extenso* before the Society. In all but two of the nine cases, catgut prepared according to the old plan was used for ligatures, and perfect recovery ensued. Mr. Lister attributed the success which had attended him to observance of certain precautions, viz.: (1) to use only reliable (tested) catgut; (2) to adopt rigid antiseptic treatment until the wound has entirely healed.

The older method of preparing catgut ligatures is so tedious, and at times, uncertain, that it became desirable to find some better and simpler plan of securing as good results. After a series of experiments, extending over two years, Mr. Lister had, at length, arrived at a means of so preparing it,

that it could, at all times, be readily and easily made. He found that the "seasoning" of the catgut is a material improvement to it, and sought, therefore, to develop similar qualities in a shorter period of time. Having described the method of manufacturing catgut from the small intestine of the sheep, Mr. Lister proceeded to describe the experiments to which he resorted, in order to convert this into a surgically serviceable material, possessing the following characteristics, viz. :—1. Strength, so that it may resist the strain of the hands in tying; 2, power of resisting the softening action of blood serum, so that the knot made on it may remain firm throughout; 3, pliancy, thus avoiding the rigidity of catgut over-prepared under the old plan; 4. softness and an unirritating presence, while being yet not too rapidly absorbed; 5, firmness throughout the whole period of absorption. During the time over which his trials extended, he frequently obtained catgut which would answer many of these requirements, sometimes even all save one, but only recently had he been able to secure *every* one. Tannic acid produced a catgut in all respects admirable, save that it was absorbed too rapidly, an objection attaching also to kid leather, which some authorities recommended for ligatures. Chromic acid alone, proved useless. With glycerine, however, it yielded better results. About this time, Mr. Oliver Pemberton, of Birmingham applied to Prof. Lister for catgut, to be used as ligatures at a special operation, and he received a supply of that prepared by the chromic acid method. The patient did well for a time, but eventually the wound suppurated, and the ligature at length was discharged in a rigid and wire-like condition. It was "over-prepared," and acted as an irritant, and in one German school it is an invariable experience that the ligatures come away for the same reason as produced the result in Mr. Pemberton's case.

The effects produced on catgut by a one in twenty water solution of carbolic acid is greater than that by carbolised oil, hence by blending the two the best result is obtained, and a most admirable preparing fluid is formed. The mixture which finally gave the catgut answering all the requirements named, and producing these in so short a time as 48 hours, consists of chromic acid one part, pure distilled water 4,000 parts, pure phenol (carbolic acid) 200 parts. The amount of catgut introduced into the mixture should equal in weight the chromic acid employed, and at the end of forty-eight hours it ought to be removed, dried, and kept in carbolised oil, one to five. The quality of the catgut is necessarily to some extent dependent on the sheep from which it has been obtained. The intestines ought to be fresh, and it is wise to procure the supply from a maker in whom implicit trust can be placed. When in store, the ligatures should be kept well coiled, to ensure that they will not give in the wound, the tension to which they are subjected while stored being regulated to ensure that this shall not take place. Catgut of common size prepared as thus recommended should stand a strain of about thirteen pounds. A portion,  $2\frac{3}{4}$  one-hundredths of an inch in diameter, when tested, broke under thirteen pounds six ounces. It was then steeped for half-an-hour in serum at 98° F., and at the end of that time being again tried, it bore eleven pounds four ounces before giving. Mr. Lister expressed his conviction that the catgut in a wound does not undergo chemical solution, but that actual *absorption* of it occurred in the same way as non-putrid bony sequestra are absorbed. The time usually occupied in the process of absorption is about twenty-one days. Erosion first begins about fourteen days after the introduction of the ligature, and in proof he

exhibited a ligature removed at the end of ten days, on which no action had been exerted. He also showed the carotid artery of a calf, on which it had first been demonstrated that the catgut ligature is replaced by organised tissue. Mr. Lister concluded his exhaustive and admirable address by protesting against the misrepresentation which made him appear to declare that the catgut ligature in a wound becomes actually revitalised. He had never been guilty of such an absurdity, but asserted only that living tissue replaces the catgut as absorption advances.

## CLINICAL LECTURES

ON

### INFANTILE PARALYSIS, AND ACUTE ANTERIOR POLIO-MYELITIS IN ADULTS. (a)

By THOMAS BUZZARD, M.D., F.R.C.P.,  
Physician to the Hospital for the Paralysed and Epileptic.

#### LECTURE I.—(Continued.)

GENTLEMEN,—I would remind you that motor impulses from the brain travel to the muscles for the most part by the lateral column of the spinal cord opposite to the hemisphere in which they originate. In the anterior horns of grey matter they act upon large ganglionic cells, and it is through the medium of these (and not as a rule directly), that the motor impulses are transmitted to the muscles by the anterior roots of spinal nerves continuous with the cells. The ganglionic cells are also the reflex centres by which afferent impulses conveyed from the periphery by the posterior roots, give rise to muscular contractions. There is no reasonable doubt also, that the centres of nutrition for the muscles lie in the cells of the anterior horn of the spinal cord. Destruction of these cells, or such a lesion as without being absolutely destructive suspends their action for a longer or shorter period betrays itself, by paralysis, by such an alteration in the motor nerve going to the muscle as renders it incapable of being stimulated by electric currents, by wasting and degeneration of the muscular structure, and by absence of muscular contraction brought about by reflex action.

The anterior horn of grey matter contains the largest cells that are to be found anywhere in the cord. These are clustered in three groups, of which the most important is usually found towards the outside of the anterior part of the horn. The cells have prolongations which, according to Deiters, receive a coating of myeline and thus become continuous with the nerve fibres of the anterior root. Huguenin describes the anterior root as composed partly of fibres thus connected with the cells of the anterior horn and of others which quit the grey substance and pass into the lateral columns in an upward direction. (a)

It is essentially in the anterior horn of grey matter that the pathological change occurs which has been described by Prévost, Vulpian, Lockhart Clarke, Charcot, Joffray, Roger, Damaschino amongst others, and last year in admirable detail by Dr. Turner, Dr. Taylor, and Dr. Humphreys at the Pathological Society.

(a) Delivered at the National Hospital for the Paralysed and Epileptic.

(a) It appears to me possible that the existence of some fibres which run in the anterior roots and pass into the lateral columns without direct connection with the ganglion cells, may explain the circumstance that a certain amount of voluntary power will often return in this disease before the nerve-trunk shows excitability to electrical currents, and whilst the muscle still fails to contract to induced currents. The trophic centre for most of the fibres would be the large ganglionic cells, and the fibres would therefore degenerate upon lesion or destruction of the cells. But the fibres to which I have referred above having a trophic centre higher up may be readily supposed to escape all but a temporary obstruction of function.

The changes observed by these authorities may be briefly summed up as follows :

Under the microscope, at an early stage, areas of inflammatory softening are found in the grey substance of the anterior horns, especially in the lumbar and cervical enlargements of the cord. In these areas of disintegration the substance is soft, friable, and disseminated with numerous granulation-cells, the blood vessels overcharged, and there is increase of connective tissue, with its nuclei. The large multipolar ganglion cells have, in great part disappeared—entire groups having vanished, whilst of those that remain some are degenerated and atrophied, others undamaged. The nerve fibres and axis cylinders within the area of softening have also disappeared. The anterior horn as a whole appears wasted. There is often also some overgrowth of connective tissue with wasting of nerve fibres in the antero-lateral columns.

The anterior roots are diminished in size, atrophied, and under the microscope show signs of degenerative atrophy; those most changed corresponding with those parts of the anterior horns, where the lesion is most pronounced.

Observations made many years after the attack show firm connective tissue, with thickened blood vessels in the areas of destruction, with large numbers of corpora amylacea. The ganglion cells and nerve-fibres are more or less extensively destroyed—those remaining being in all stages of degeneration. There is more or less sclerosis of the antero-lateral columns.

Now, the effect of section of a nerve is to bring about, within a week, structural changes which can be traced throughout its ramifications. And lesion of a ganglionic cell with which a nerve fibre is continuous, has a similar effect to section of the nerve. As a result of these changes, not only does the nerve cease to transmit motor impulses, but it is rendered inexcitable by electrical stimuli. When you apply the two rheophores of an induced current machine to the skin covering a muscle, and thereby obtain a contraction of muscular structure, that contraction is brought about by the momentary current stimulating the intra-muscular nerve, and not by the action of the current directly on the muscular fibre. So that when, as a result of destruction of ganglion cells, the motor nerve roots going from them to the muscle undergo a change, the effect necessarily is that you fail to produce contraction of the muscle by applying the induced current. This failure of response then merely shows that there is something wrong with the nerve. If now you apply a voltaic current you will find that on making and breaking the circuit contractions occur. This is because this form of electrical stimulus acts directly upon the muscular fibre itself. The mere absence, therefore, of response in a muscle to the induced current is quite compatible with integrity of muscular structure. It is probable that muscular structure retains its electrical contractility for a very long time after it has lost its physiological connection with the trophic centre in the spinal cord.

The principal, as well as the earliest, change which the paralysed muscle undergoes in this disease is one of simple atrophy. Laborde found this as early as fifteen days after the onset.

Portions of muscular tissue have been hooked out by means of a "harpoon" from the living, and examined microscopically. It would seem that in the first period of the disease, i.e., within the first few months, a great number of fibres are found in a state of simple atrophy, of very small diameter, but with the natural striation, and without traces of fatty granulations. Amongst them are a few presenting different degrees of granulo-fatty degeneration. With this there is often considerable overgrowth of connective tissue. In the second period, fatty substitution is largely added, according to Charcot, to the preceding changes. Masses of granulations and fat globules are substituted in the sheaths of sarcolemma for the primitive fibre which has disappeared. In other parts the adipose cells accumulate outside the sarcolemma in the intervals separating the primitive fasciculi. Hayem de-

scribes how in some cases the interstitial tissue is in much excess, and the muscles are converted wholly, or in part, into a hardened fibroid tissue in which the thin and discoloured fasciculi are distant from one another. The anomalous development of adipose tissue gives a lipomatous consistence and development which may mask the muscular atrophy, and produce a pseudo-hypertrophy.

The patient whom I now show you, and who was attacked with infantile paralysis fourteen months ago, illustrates some points of importance connected especially with the diagnosis of the disease.

CASE II.—Daisy A., æt. 1½, was admitted into the hospital on October 6th, 1880, on account of paralysis of the right arm. She had been attending as out-patient since July; notes of her case were taken by Dr. Beever.

The child is said to have had enteric fever when three weeks old—otherwise it had been fairly healthy. About a year ago, the mother noticed one day that the child seemed sleepy and feverish. Next day when she was moved she "twitched her eyes upwards," and her arms were convulsed: not her legs. Her mother thinks she lost consciousness for three days. During this time she was convulsed, mostly when she was moved. Directly after this her mother observed that her "eyes were crossed," and that she "equinted inwards." This appears to have lasted ten days.

The right arm was not observed to be affected until ten days after the twitching, when the mother noticed that the arm was always behind the child's back, and could not be brought forwards, and it fell, if lifted, like a dead weight. Neither the left arm nor the legs were affected. For about three days it is said the hands were closed, and it made her scream when an attempt was made to open them. She has not been able to move the right elbow or shoulder-joints at all.

The girl is thin and sickly looking. The right arm is smaller than the left, the deltoid and biceps being especially wasted. She can move her fingers and hand, but cannot flex the elbow-joint, though she can extend it. She cannot abduct the right arm from her chest.

The muscles of the right arm show no response to faradism. They re-act to the constant current interrupted.

When I tap the tendon of the supinator longus of the left arm the muscle contracts and causes a sudden flexion of the forearm. (The supinator longus is, as you are aware, in spite of its name a flexor of the forearm on the arm.) On the right (affected) side a similar manoeuvre produces no result. The tendon reflex is absent, then, at the wrist of the paralysed arm.

In such a case as this, and especially having regard to the unusually severe head symptoms by which it was attended, the suggestion first arises that it is probably a case of hemiplegia of cerebral origin.

Now if this were a case of cerebral hemiplegia and you applied the test which I have just shown you, one of two results would certainly have followed. Either there would have been no difference between the two arms, or the reflex on the affected side would have been stronger than that on the sound side.

I will show you a child of about the same age, Florence W., æt. 16 months, who lost the use of her right arm and leg three months ago. She had been laid up on account of diarrhoea, and it was when she was taken up after this that the paralysis was first observed. You will notice that the right leg although weak, is not at all wasted, and that the patellar tendon reflex on that side is somewhat in excess of that of the other side. The limb is not stiff. The upper limb shows some rigidity, and in this the tendon reflex at the wrist is greatly in excess. The contrast is very striking with what I have just shown you in Daisy H. There can be no doubt that this case is one of cerebral hemiplegia. Two circumstances, I may add, go to confirm this. We find, on inquiry, that the child's face was at first paralysed, although that has since recovered, and there was marked cutaneous anaesthesia of the affected limbs for three weeks.

The absence of the tendon reflex of the wrist has the same significance in the case of Daisy H. as did that of the patellar tendon in the other cases shown. It is evidence of a break in the nervous arc which connects the tendon with its muscle through the mediation of the spinal cord. In order to find out, as far as that is possible, the situation of the break we apply induced currents of electricity to the muscles of the arm. There is no contraction. When, however, we apply a constant current, and slowly interrupt it, we obtain contractions. This is what is called the reaction of degeneration, and its presence signifies that the muscle is physiologically cut off from the influence of the spinal cord. Now, this influence can evidently be cut off in two different ways. Either the nutritive centre itself, in the spinal cord, may be diseased, or there is some solution of continuity in the spinal nerve passing to the muscles, brought about either by disease or injury.

There is no loss of sensibility in the skin of this child's arm. We may take it, therefore, as certain that the break of continuity, supposing this to be present, does not affect the nerve trunk, since this is both motor and sensory in its function. A spinal nerve arises, as we know, by two roots of which the anterior is concerned in the propagation of motor impulses, the posterior in the conduction of sensory impressions from the periphery to the centre. It is evident, therefore, that the pressure of a destructive lesion involving the *motor roots* only of several nerves going to form the brachial plexus might explain the paralysis and wasting of muscles which we see in this case, as well as the absence of tendon reflex and of reaction to faradism. But the anterior (or motor root) of a spinal nerve as I have before remarked, is in intimate association with the large ganglionic cells which are found in the anterior horns of grey matter in the spinal cord. Lesion of this structure, involving atrophy of the cells in question, brings about the same results as a destructive lesion of the anterior roots which are in intimate relation with these ganglionic cells. As far as regards the particular symptoms which we are considering, we cannot, by the tests applied, say whether the lesion is in the right anterior horn of grey matter, or in certain anterior roots of spinal nerves emanating from the cervical enlargement of the cord. No doubt a spinal meningitis, with resulting effusion, might explain the condition, but we should have to imagine the inflammation to be of so limited a character as to make the explanation an improbable one. It would have to be limited in extent horizontally to one half of the anterior portion of the cord, and perpendicularly to the points of egress of a few of the anterior roots. On the other hand, let me draw your attention to the important fact that, whilst the deltoid (supplied by the circumflex nerve) is most paralysed of all the muscles, the triceps which, with others, is supplied by the musculo-spiral is one of those least affected. As you see, the elbow-joint can be well extended. Now, as it will be remembered, the musculo-spiral and the circumflex are the most important divisions of the posterior cord of the brachial plexus, and could hardly fail, therefore, to be equally affected if the lesion were one of anterior nerve roots.

We are driven then by exclusion to the certainty that the paralysed and atrophied state of the muscles here seen depends upon lesion of the large motor ganglion cells in the right anterior horn of the cord. Moreover, this brings us to another point of extreme interest in regard to the relation borne by the ganglionic cells to the innervation of the muscles.

I long ago learned from Dr. Hughlings Jackson his opinion that the groups of ganglion cells in the anterior horns of the spinal cord represent *movements* not muscles, and Remak has recently published some important observations bearing upon the same point. He has come to the conclusion (*Centralblatt*, 1879, p. 939) that in anterior polio-myelitis and lead palsy the groups of ganglion cells corresponding to the muscles *functionally associated* lie together in the grey substance of the cord,

inasmuch as those muscles have been found diseased together, which work together synergically without reference to their innervation by this or that nerve. According to his experience, there are typical combinations of muscles diseased which must correspond to constant and definite territories for movement in the spinal cord. For example, there is an upper arm type in which of all the muscles the deltoid, biceps, brachialis anticus, and the supinators are alone attacked with degenerative atrophy. One of these muscles will not be attacked severely without the others showing, if only trifling, electro-diagnostic signs of degeneration. He remarks upon the escape of this sartorius in affections of the district of the anterior crural nerve and the sparing of the tibialis anticus in affections of the peroneus district.

(To be continued.)

## DISEASES OF THE HEART IN CHILDREN.

By W. H. DAY, M.D., M.R.C.P. Lond.;  
Physician to the Samaritan Hospital for Women and Children.

(Concluded from page 69.)

### HYPERTROPHY AND DILATATION.

**HYPERTROPHY** of the heart, which consists of an increase in its muscular tissue, is owing to the greater effort which the organ makes to overcome the obstruction to the passage of blood through its cavities.

In children it is noticed as a consequence of valvular disease (especially mitral obstruction or regurgitation), adherent pericardium, emphysema of the lungs, and chronic renal disease.

The *physical signs* are heaving impulse, diffused over a large space, visible to the eye, and raising the ear of the listener, when the head is applied to the cardiac region. The apex beat may be seen and felt between the sixth and seventh ribs, or even lower. The pulse is full and strong in simple hypertrophy, but if accompanied with dilatation, the force of the arterial stream is considerably lessened. The heart's sounds are dull or muffled, and very rarely accompanied by murmur. The area of dulness is increased laterally, and to the left of the sternum when the left ventricle is involved. When pulmonary emphysema is present, the percussion dulness is masked through the margins of the lungs overlapping the heart. In rickety subjects the præcordial region is sometimes rounded or prominent. When the right ventricle is affected, which is common in long standing cases, epigastric pulsation is noticed, and the margin of the ventricle can be felt to the left of the ensiform cartilage. When obstruction exists at the mitral orifice (most common in children), the left auricle becomes overfilled with blood and its cavity enlarged. As the blood accumulates in the pulmonary circuit, the right ventricle gradually becomes hypertrophied and dilated, so that one cavity after another becomes more or less affected. In mitral disease, the left ventricle may remain stationary or contract in size, whilst the left auricle is chiefly enlarged; the heart is globular or rounded in form, and the apex chiefly consists of the right ventricle.

The *constitutional symptoms* necessarily vary according to the mischief which has produced the hypertrophy. The walls yield and the cavities undergo *dilatation* if the heart becomes enfeebled from over-exertion. The diaphragm is depressed, and the enlarged heart tends to displace the lungs. General dilatation of the cavities is usually seen in fat and feeble adults who have suffered from menorrhagia, chronic bronchitis, or other exhausting illness, but in children it is most frequently the result of mitral regurgitation.

Hypertrophy of the heart, associated with more or less dilatation, is a common attendant on chronic kidney disease. The left ventricle is most frequently involved. It arises from overgrowth of muscle, in consequence of an obstacle in the smaller arteries and capillaries, which the heart is striving to overcome. These vessels become contracted,

and cause high tension in the vascular system, because the structural change in the kidney prevents the elimination of urea, and other products of metamorphosed tissue, which accumulate in the blood and lead to thickening of the smaller blood vessels, hypertrophy, dropsical effusions, and hæmorrhages.

The general signs of dilatation are a frequent, weak or irregular pulse; the veins of the neck are often prominent when the right side of the heart is affected, and if the case proceeds from bad to worse, there is dyspnoea, bloated face, anxious countenance, and finally œdema or dropsy. The physical signs are a thumping action of the heart, if there is much hypertrophy, but if not, those of dilatation may prevail, and then the impulse is weak, short, or tremulous. The first sound is feeble and diffused.

The causes of dilatation, pure and simple, are anæmia and general debility, bronchitis and emphysema of the lungs, but it is usually associated with valvular diseases as we have seen, and then the symptoms vary according to the orifices chiefly affected, and the degree of hypertrophy present.

The treatment is that of valvular diseases of the heart, with which both conditions are so closely associated.

With respect to malformation of the heart, the septum which divides the ventricles is occasionally deficient, and the two cavities communicate. The foramen ovale is also large and open in some cases, or the folds of membrane are not sufficiently developed to close the orifice, so that the blood passes from the right auricle into the left auricle. For an interesting account of these various irregularities, the reader is referred to Dr. Peacock's excellent work. (a)

With this condition there is often contraction at the orifice of the pulmonary artery, which may be so reduced in size as barely to admit a quill. If the contraction is considerable, and the foramen ovale large, the right ventricle is small, and there is hypertrophy and dilatation on the left side.

*Cyanosis—Morbus Cœruleus—Blue Disease.*—The symptoms of this peculiar affection are a blue tint of the skin, tongue and lips, and a general coldness of the surface. The patient is subject to palpitation and violent action of the heart, faintness and syncope; the pulse is feeble and sometimes irregular, and bronchitis, congestion of the lungs, hæmoptysis, and serous effusions are apt to supervene, when the disorder is of any considerable duration.

Among the physical signs, the existence of a murmur is generally to be detected over the point of communication. In the following case there was no bruit.

N. C., æt. 3, was admitted into the Samaritan Hospital under my care, October 22, 1877, with well-marked symptoms of this disease. The mother attributed the symptoms to the shock of a gunpowder explosion in Regent's Park, but the child had suffered from whooping-cough aborily after birth, and at the time of the explosion had a severe cough. On admission, the countenance was deeply congested, and the lips were of a claret hue; the swollen eyes stood forward in their sockets, and the eyelids were œdematous, the feet and hands lacked warmth, and presented the same venosity as the face. The child was constantly turning and twisting about in bed to obtain ease, and when fretful and irritable was darkest in colour. Sometimes she would lie on her face, sleeping for hours together, and resenting any interference. The pulse was 140, contracted and small; respiration, short and shallow. The chest both in front and behind was resonant, and traversed the whole circuit of the lungs. The bowels were regular; urine sp. gr. 1018, fair in quantity, pale, slightly clouded, non-albuminous, and of neutral reaction.

No murmur could be heard over any of the heart's orifices, the sounds being distinct throughout the cardiac region, as well as posteriorly. The action resembled an excited and palpitating heart, and was much worse at one time than at another. The temperature on admission was 100°, at the end of ten days it fell to 98·4, when the

mother took the child out of the hospital. Death took place a month afterwards.

The causes are a communication between the auricles, or a single auricle and ventricle, or narrowing of the pulmonary artery, and mitral orifice. Opinions are much divided on the causes which induce this discoloration of surface. The case of a male infant, nine months old, is recorded by Dr. Cayley, in which the aortic valves were extensively diseased. From birth the child was short of breath, and when first brought for treatment there was dyspnoea, but no cyanosis. The cardiac impulse was much increased, and there was a loud systolic murmur over the cardiac region. Before death there was some degree of cyanosis. "On post-mortem examination the left ventricle was found much hypertrophied. The aortic orifice was much constricted, and the valves were covered with large, firmly adherent fibrous vegetations, evidently of long standing." (a) It has been attributed by some authorities to general congestion of the venous system from obstruction at the pulmonary orifice (*pulmonary stenosis*) (b) to the admixture of venous with arterial blood by others; whilst there are those who contend for the presence of venous blood in the arteries and general circulation, as the true explanation of the lividity. It has been stated by Dr. Stillé, that cyanosis may exist without the intermixture of the currents of blood, and that intermixture may take place without any cyanosis. M. Valleix does not think that a communication between the right and left cavities of the heart is a certain proof of cyanosis. It is, however, generally regarded as due to venous congestion, and the mixture of arterial with venous blood. The latter hypothesis seems the most correct, and as Dr. Walshe truly remarks, the most intense venous obstruction may exist in the adult without producing cyanosis. Dr. Peacock regards cyanosis as due to congestion of the venous system. Though it would seem difficult to determine the exact condition, it is not improbably due in some instances to the fullness of the venous radicles, and imperfect aeration of the blood.

The prognosis is most unsatisfactory. The child may die from syncope, or in a fit of coughing and urgent dyspnoea from congestion of the lungs. Instances are recorded of adult life being attained, "and in one case recorded by Louis, the age of fifty-seven was reached." (Hooper's *Vade Mecum*, by Dr. Guy and Dr. Harley, 1874, p. 425.)

The treatment consists in rest, pure air, and warmth, careful diet, and attention to the digestive organs.

### COLLES'S FRACTURE. (c)

By JOHN F. KNOTT, F.R.C.S.I.

(Continued from page 71.)

In a communication made a few years later to the *Archives Gênerales de Mèdicine*, Diday discusses at greater length the mechanism of this fracture. This he tried to define with mathematical precision, and explains the obliquity of the line of fracture by the decomposition into two forces of the action of the weight of the body in falling, on the radius inclined to the ground at an acute angle. According to the law of parallel forces, one of these is parallel to the ground, and is necessarily and completely neutralised; the other is perpendicular to the same plane, and is consequently the only one which is able to act. But this vertical force intersecting the shaft

(a) Path. Trans., 1875, vol. 25, p. 83.

(b) Dr. Peacock showed before the Pathological Society, Oct. 15, 1878, a specimen of stenosis of the pulmonary artery from disease of the valves, which he believed to be congenital. The boy was 13 years of age, always livid, and never strong. Dyspnoea and increased lividity came on a short time before he was admitted into hospital. "There was a loud double murmur over the pulmonary cartilage, and a distinct thrill." The patient was dropsical and died. After death the right ventricle was found dilated and hypertrophied, and the orifice of the pulmonary artery narrowed and funnel shaped.

(c) Read before the Surgical Society of Ireland.

(a) "On Malformations of the Heart," 2nd edit., 1866, p. 107.

of the radius in the oblique position into which it is naturally thrown at the moment of falling, "it is clear that the solution of continuity ought, as in all fractures by *contre-coup*, to follow the same direction as that of the force which produces it, and in this case will follow an oblique line running downwards and forwards in relation to the radius, considered in the position which it occupies in the subject in the vertical posture." The same explanation applies to the reverse obliquity of the line of fracture in the rarer cases where it is produced by a fall on the back of the hand. He also lays much stress on the shortening of the broken radius, which is produced by the over-riding of the fragments, and, in his experience, was invariably present, amounting in some cases to five or six lines. The backward displacement of the carpus, and the projection of the inferior extremity of the ulna in front are also pointed out. The shortening of the radius has the effect of throwing the surfaces of the inferior radio-ulnar articulation out of their mutual contact, and hence the difficulty of the movements of pronation and supination, which so often remains for a considerable period after the union of the fracture.

In 1842, Velpeau, in his article on the subject in the *Dictionnaire de Médecine*, occupied himself chiefly with the consideration of the diagnosis, and pointed out two new signs which, he believed, would secure the practitioner from every possible error. The first of these is the constant deformity "*en Z*," which, he believed, to be pathognomonic of fracture of the lower end of the radius; the second is the elevation of the external radial tendons, which, instead of lying, as in the normal state of the parts, close to the surface of the bone, come to stand out prominently beneath the skin, separated from the back of the lower part of the radius by an interval of six or eight millimetres. The Z-shaped distortion is manifest, whether the affected limb be viewed in profile, or antero-posteriorly. In the former aspect, one branch of the Z is formed by the axis of the radius, the other, extreme by the vertical axis of the carpus, while the intermediate link is represented by a line from the inferior extremity of the prominence formed at the seat of fracture in front, to the superior extremity of the carpal prominence behind. The general outline of the back of limb in the vicinity of the seat of fracture he likens to that of a dinner-fork.

This same year of 1842, marks an epoch in the literature of fractures of the lower end of the radius, for it saw the publication of the important *memoire* of Voillemier, the most elaborate and exhaustive which had yet appeared on the subject. According to this ingenious writer, the most frequent form of fracture met with in this situation is what he has described under the name of *fracture par penetration*. For the correct understanding of his hypothesis, we must make ourselves acquainted with the exact structure of the lower end of the radius. The layer of compact tissue, which forms nearly the whole thickness of the shaft of the bone at its middle, rapidly diminishes in thickness as it approaches the carpal extremity, and, for the last centimetre, is nearly as thin as ordinary parchment. In front a layer of tolerable thickness is prolonged a little farther down than on the posterior surface. Accordingly, in a fall on the hand, when the force is transmitted directly from the carpal bones to the lower end of the radius, a solution of continuity is immediately established at the place where the investing wall of compact tissue has nearly ceased to exist, and the continuation of the force causes the solid tube of compact tissue to penetrate the substance of the spongy mass beneath. If the force has been moderate, the degree of impaction is slight, merely causing a firm interlocking of the fragments, whereas, if the violence happens to be extreme, the superior fragment continuing to descend, crushes the carpal portion between it and the bones of the wrist, and dividing it into a number of pieces, establishes the condition described by Dupuytren under the name of *fracture par écrasement*. In the great majority of cases, however, according to this writer, the oblique position of the limb causes the force to tell more effectually on the posterior part of the articular end of the bone, and, espe-

cially, because this part rests more directly on the carpal bones, and is placed more in a line with the axis of the shaft of the radius. Accordingly, the impaction of the upper into the lower fragment commences posteriorly, while the latter is, at the same time, carried somewhat backwards, while the posterior wall of the upper fragment penetrates the spongy tissue of the lower; the anterior, on the contrary, overlaps the latter in front, so that the impaction is reciprocal. When examined from within outwards, a similar disposition is found. The outer border of the brachial fragment will be found penetrating the carpal piece in the direction of a vertical plane, which, if prolonged, would separate the styloid process from the shaft of the bone, while the inner margin, on the contrary, is seen to override that of the lower fragment. The obliquity of the plane of fracture, then, according to Voillemier, is really apparent, and the delusion is due to the backward deviation of the lower fragment, and the greater depth of the posterior penetration. The evidence on which he relies as being absolutely conclusive of the truth of his theory, and which he never failed to find when looked for, is a vertical line of compact tissue, imbedded in the cancellous structure of the lower fragment, and which, when traced upwards, is found to be directly continuous with the investing layer of the shaft of the bone. In the rarer cases in which the lower fragment is displaced forwards, the line of compact tissue is found to be continuous with the anterior wall of the shaft, but in no case is a second line present even when the carpal fragment has undergone the smallest possible amount of deviation from its normal axis. From the apparent dilemma offered by the latter case, Voillemier extricates himself by pointing out that although reciprocal penetration always takes place, the compact covering of the lower fragment is so extremely fragile that it offers no resistance, and is, in a great measure, broken up at the time of the injury. Another mechanism is recognised by this writer in explanation of the occurrence of a much less frequent form of fracture which is met with in the same vicinity. Experiments on the cadaver had proved to him that extreme flexion or extension of the hand nearly always had the effect of wrenching off a piece of the lower end of the radius, and, in this way, he believed, should be explained the epiphysary disjunction so often seen in young subjects. In more advanced life, a fracture occurring in this way, sometimes engaged the articular surface, and removed an oblique slice, either anteriorly or posteriorly, and, in other cases, detached a fragment of the usual length from the whole thickness of the bone. In none of these cases, according to Voillemier, is there any considerable deformity, and accordingly to the class of *fractures par anachement*, he would relegate all those cases in which, after a history which would lead to a suspicion of fracture, the predominant symptoms indicate merely the existence of a sprain, where deformity and crepitus are absent, and an obscure mobility is the only local sign justifying the opinion that a solution of continuity of the bone has taken place. He narrates two very remarkable cases in point: one in which a fall on the anterior surface of the lower half of the hand was the cause of the fracture, and a second, a very powerful young man had had his wrist violently flexed by one of his comrades in playing. In both the signs were of the obscure kind above described.

With regard to the local signs of the typical form of fracture, Voillemier insists that the abduction of the hand on which Dupuytren laid so much stress, is more apparent than real. In those cases in which it is most pronounced, the axis of the hand is merely brought to approach that of the fore-arm, but in the great majority of the cases, the hand completely preserves its normal position of adduction. He dwells at some length on the antero-posterior distortion of the limb, in which the long axis is broken up into three parts, forming so many inclined planes meeting at obtuse angles; one formed by the upper fragment, a second, by the lower, and a third, by the carpus and metacarpus. The radial border of the limb will be found, on examination, to present a similar deformity, so that laterally, as well as antero-posteriorly, a single *coup d'œil* will

suffice to recognise the characteristic Z-shaped deformity, as it was happily described about this date by Velpeau. Voillemier entirely rejects the rotatory movement of the lower fragment around the triangular fibro-cartilage so carefully described by Goyrand, as well as the *mouvement en bascule*, of Pouteau; while the absence of mobility and crepitus, as well as the unmistakable distortion, are accounted for by the mutual impaction of the fragments of the broken bone.

Nélaton, in his *Pathologie Chirurgicale*, published in 1844, adopts the impaction theory of Voillemier, with the slight modification that reciprocal impaction is very rare, the brachial fragment alone penetrating the other, and only at the posterior part. He also makes the plane of fracture transverse; but, contrary to Voillemier, considers abduction of the hand to be frequently present. The triangular fibro-cartilage generally loses its attachment, either from laceration of its fibres, or fracture of the styloid process of the ulna, and so shortening of the radius is allowed to take place, with a semi-luxation of the inferior radio-ulnar articulation. He describes in terms more clear, perhaps, than those of any preceding writer on the subject his ideas of the mechanism of the fracture. The fore-arm, in a fall on the hand, forming a right angle with the latter, comes to press directly on a kind of arch formed by the first row of carpal bones, and the latter resists in supporting itself (1) on the ground by its internal extremity formed by the pisiform; (2) on the trapezium by its external pillar which is formed by the scaphoid; (3) on the centre formed by the os magnum and unciform. The radius being pressed between the weight of the falling body on one side, and the resistance of the ground transmitted through the carpal bones on the other, yields at a short distance from the articulation.

We have already referred to Bouchut's account of his experiments on the dead body with the view of deciding the question of the possibility of producing a dislocation of the wrist-joint. He sacrificed to his zeal for truth, both fore-arms of twenty bodies, but all his efforts to obtain a carpal luxation were useless, the radius, in every case, gave way either to extreme flexion or extreme extension, more easily to the latter. Malgaigne had previously (in the year 1832), firmly denied that there was any such thing on record as a *bona fide* example of dislocation of the wrist, and after examination, rejects summarily the only three cases which the literature of surgery then afforded, and which had been reported on the authorities of Ravaton, Thomassin, and Cruvelhier respectively. Roquetta two years later, in a valuable essay on the subject, arrives at the same conclusion, and adds some judicious remarks on the epiphysary separation which occurs in children.

(To be continued.)

## Clinical Records.

### ST. BARTHOLOMEW'S HOSPITAL.

#### *A Case of Uterine Fibroid—Recovery.*

Under the care of Dr. MATTHEWS DUNCAN.

ELIZABETH ANNE S., *æt* 38, was admitted to St. Bartholomew's Hospital on the 3rd of July, 1880, with the following history:—

She had been married sixteen years, but during that time had had no children born alive. She had, however, had one miscarriage three months after her marriage. Her catamenia had commenced when she was 16 years old. She had been, on the whole, regular, the catamenia lasting about two days, and being always painful. For the preceding four years she had had profuse menstruation, and during the latter part of that time the catamenia had lasted longer and been more frequent. During the last six weeks there had been an almost continual loss of blood. Further, she had been troubled with palpitation.

On admission she was found to be extremely anæmic, and

had a yellow offensive discharge from the vagina. She complained of a pain in the left iliac and hypogastric region, which she said was much more severe at times. The bowels were open regularly, and there was no difficulty about defæcation or micturition. The legs were œdematous, pitting on pressure; the temperature normal. By means of the stethoscope a presystolic murmur was detected at the apex, and a systolic (probably anæmic) murmur at the base. There was also a *bruit de diable* in the neck. The urine was acid, specific gravity 1010, and contained no albumen.

Dr. Matthews Duncan examined the patient in the afternoon with the following results:—

Per hypogastrium—The belly was natural in appearance, but on palpitation he detected a rounded, tender, displaceable hardness projecting on the left side of the brim of the pelvis; the hardness was dull on percussion over a very limited area, and surrounded by resonance on every side.

Per vaginam—The cervix uteri projected into the pelvis, being on the perinæum and near the os vaginæ; the body of the uterus was evidently enlarged, and the lump felt, per hypogastrium, had a close connection with the enlarged uterus. A probe entered the uterus, on the right side of the tumour, nearly three inches.

The patient was put on a meat diet, with one pint of milk and pudding, and was ordered the following prescription:—

Ext. ergotæ liquid, ℥xx.;  
Tinct. zingib., ℥xx.;  
Tinct. nucis vom., ℥v.;  
Aq. ad. ℥j. ter die.

The following notes indicate the subsequent progress of the patient:—

July 6th.—There has been no loss of blood since admission; the patient complains of more pain in the left iliac fossa.

8th.—Pulse, 120; temp., 103°6. Dr. Matthews Duncan introduced into the uterus a guarded knife, and incised the capsule of the tumour. Very little bleeding followed the operation. The patient was ordered 1 drachm of ergot instead of 20 minims. She had a slight rigor an hour after the operation.

9th.—Patient had been sick twice. She complains of pain in the left hypogastric region. There is still a little loss of blood. Morning temp., 104; pulse, 140, small. Skin moist; one cheek slightly flushed. No bearing down pains as yet. The diet was altered to a milk diet, with beef-tea, 2 ounces of brandy and soda-water; and it was ordered to add to the medicine—

Quinis sulph., gr. iij.;  
Acid sulph. dil., ℥vj.

10th.—Slept poorly. Very thirsty. Tongue a little furred. Temp., 104; pulse, 126, small. Mr. Nall, the Obstetric Resident, syringed out the uterus with carbolic acid, 1 in 40, both morning and evening, and continued to do so on subsequent days. Ordered—

Pil. opii, gr. ʒ. ter die.

11th.—Fair night. Patient takes her food better, and is less pain.

4.30 p.m.—Has been vomiting; rigor.

12th.—Restless night. Throat sore. Sick a little in t night. Ordered—

Garg. pot. chlor.

9.30 p.m.—No pain; sweating a good deal.

13th.—Discharge rather more fetid.

15th.—Cervix much higher, and harder to reach. Discharge rather stained and fetid.

16th.—Some shreds discharged. Ordered—

Hæustus ferri et ammonia citritis.

18th.—Great deal of foul discharge. The operation of syringing appeared to be more painful. Evening temp., 100°2°.

21st.—At 1 p.m. this morning the patient passed a fibroid tumour measuring 3 in. by 2½ in. by 1¼ in. Along with it was a good deal of fetid discharge. Temp., 100; pulse, 120, small and weak. No pain.

22nd.—Slept poorly. Tongue cleaner. Uterus on syringing much cleaner. Uterus situated higher up.

23rd.—Feels comfortable. Slept well.

27th.—Slept better. No discharge nor smell.

The patient now appeared to be progressing favourably towards recovery, but on the night of the 30th a relapse occurred.

31st.—Slight chill last night. Temp. rose to 103°; pulse,

92. Temp. this morning 99°. No discharge. Evening temp., 103'4.

Aug. 1st.—Morning temp., 98'8.

2nd.—Ordered tr. belladonnae, viiss. to be added to the medicine.

10th.—Patient was again examined. *Result*: Per hypogastrium—nil. Per vaginam—os quite small; uterus freely movable, does not appear to be enlarged.

17th.—Had a rigor this morning, and temp. rose to 102°. No discharge.

18th.—Temp. normal.

The patient from this time continued to make a good recovery, and on Sept. 10th was considered well enough to be sent to the Highgate Convalescent Home.

*Remarks*.—This case of uterine fibroid is of interest, principally from the fact of the very rapid and complete expulsion of the fibroid tumour. The tumour was completely expelled and passed into the bed in less than twenty-four hours. Dr. Matthews Duncan stated that he had never known one passed in so short a time.

## Translaticus.

### OPHTHALMOLOGICAL EXCERPTS,

Selected and Translated

By ARCHIBALD HAMILTON JACOB, M.D. Dub.,  
F.R.C.S.I.

#### THE TREATMENT OF SCLERITIS.

GALEZOWSKI, in a recent number of the *Recueil d'Ophthalmologie*, considers it of great importance to distinguish between scleritis and sclero-keratitis. When the inflammation begins at some distance from the cornea, it is seldom complicated with iritis, and though often rebellious, disappears in the long run without leaving any trace. If the inflammation of the sclerotic begin near the cornea, serious complications in the shape of iritis and keratitis are apt to ensue, and necessitate surgical interference to prevent more or less complete blindness. For the first form Galezowski uses alternate instillations of atropine and eserine, blisters to the temples, steam douches to the eyes, and, internally, salicylate of soda if of rheumatic, and iodide of potassium if of syphilitic origin. Atropine alone induces the complication of paralysis of accommodation, which is generally more disagreeable for the patient than the slight inconvenience caused by the scleritis itself. This is avoided by using atropine in the evening and eserine in the morning. In obstinate cases, scarifications at intervals of ten days are often useful. For sclero-keratitis, iridectomy is, according to Galezowski, little short of a specific.

#### MIXED ASTIGMATISM, SUPPOSED TO HAVE BEEN CAUSED BY THE SUCKING OF THE EYE BY AN INFANT.

The following interesting case of a married lady, *set. 36*, is reported in the *New York Medical Record*, July 10th, 1880, by Dr. D. Webster:—

The commencement of her trouble dated back about eight years, when she first noticed a straight black line running obliquely across the right visual field. This line soon became crooked, and was broken up into numerous transparent specks. These floating, transparent globules eventually mostly disappeared, and the eye, after many months, settled down into a condition in which all objects seemed "distorted," and everything was "double-lined." "The gas flame," she observed, "had a halo with radii about it." She had not now, nor had she ever had, any external appearances of inflammation or irritation.

At the time the trouble was ushered in the lady was weaning her babe, and, curiously enough fell into the habit of allowing the little one to suck her right eye as a substitute for her nipple. She positively affirmed that almost every night for six months she allowed the child to go to sleep resting on her right arm, and with his mouth applied to her right eye. This gave her no pain, and she indulged the child in it, not thinking it would do her any harm. She now believes that the trouble in her eye was induced by the long continued and often repeated suction exerted on the eyeball by the mouth of her child. Examination with the ophthalmoscope reveals nothing abnormal except astigmatism. With-

out a glass the vision is 8-100, but is raised to 20-20 with — 1-10 c. axis 70° C + 1-42 c. axis 160°. The fellow eye has vision 20-20, and is emmetropic.

Whether the frequently repeated and long continued suction applied to the eye had anything to do with the change in its shape is a difficult problem to solve. For my own part, I am inclined to think that it did. It is certain that the astigmatism was developed during the period in which the eye was habitually subject to suction. It may be objected that the traction would affect only the loose and yielding eyelids. It seems to me probable, however, that the lips of the child would often make more or less pressure upon the eyeball anterior to its equatorial region. This seems to be borne out by the history of the case, for there seems to have been a slight hæmorrhage into the vitreous, probably caused by intermittent pressure upon the globe.

#### CONJUNCTIVITIS FROM CHLORAL.

Dr. J. H. Emerson, at a recent meeting of the New York Clinical Society, mentioned a case of ophthalmia produced by the use of chloral hydrate. The patient, a young man, was subject to attacks of asthma, and in two severe attacks, chloral, in ten- or fifteen-grain doses, had afforded great relief. This led him, during a recent attack, to employ it each night for some time. Shortly after he began its use the conjunctiva of the globe and lids became injected, and photophobia existed, with profuse lachrymation. The latter, as it occurred in the left eye, did not correspond with the degree of photophobia. The affection of the eyes required him to keep his bed. Iodide of potassium, which he had been taking, had been discontinued for some time, and the resulting acne and throat irritation had disappeared. There seemed to be no cause therefore, other than the use of chloral, for the ophthalmic trouble. The treatment first adopted was the application of camphor-water and borax, then of sulphate of zinc and rose water, but no improvement resulted. The chloral was then discontinued, and immediate improvement took place.

#### THE RELATIVE VALUE OF ATROPIA AND DUBOISIA IN OPTHALMIC PRACTICE.

Dr. S. D. Risley (*Am. Jour. Med. Science*), from his observation of the action of atropia and duboisia, gives the following conclusions:—1. In solutions not stronger than two grains to the ounce, duboisia sulphate is free from danger. 2. The two-grain solution of duboisia sulphate more rapidly paralyses the ciliary muscle than a four-grain solution of atropia sulphate. 3. The duration of its effect is less than half that of atropia sulphate. 4. The preparations now in the market are more liable to irritate the conjunctiva than neutral solutions of the sulphate of atropia. 5. In treatment of inflammations of the eye duboisia is quite as useful as atropia, and may, therefore, be used as a substitute.

#### DUBOISIA POISONING.

In the *Chicago Medical Gazette* Dr. Park reports the case of L. B., *set. 60*. Patient in the Illinois Eye and Ear Infirmary—service of Prof. E. L. Holmes. Left eye lost through malpractice some years ago. Has recently had iridectomy made in right eye, preliminary to cataract extraction. Has been using until lately atropia as a mydriatic, but this seeming to irritate, a solution of sulphate of duboisia (gr. j. to ʒj.) was substituted. The bottle containing this the patient carried in his pocket. One night he took purely by his own carelessness, a teaspoonful (one-eighth gr.) of this solution instead of taking it from another bottle containing diuretic mixture. The mistake was at once reported. Within eight minutes he experienced a very dry feeling in the throat and roof of the mouth, and found it impossible to articulate—the power of co-ordinating the muscles of the tongue and the oral muscle being lost. Soon after, upon endeavouring to walk, his limbs "gave way" and he found it impossible to even stand and keep his balance. He also noticed a peculiar numbness rapidly supervening in the extremities, which soon felt "as if they were asleep." Within half an hour he was totally unconscious; pulse 116. There being no resident or house surgeon to direct the treatment, there was some delay in procuring assistance. In the meantime repeated doses of an emetic were exhibited, which, however, did not act till after he was unconscious. Stimulants were used vigorously both internally and externally, as occasion seemed to demand, until four a.m., he answered questions, and by six o'clock seemed himself again. For two days subsequently there was a tremor and weakness as well as uncertainty of action about all the voluntary muscles. The fact of his having been using

the drug, and the previous condition of his eyes, made any observations at the time upon the pupil of no importance. Owing, also, to the delay in summoning the physician, no accurate and scientific account of the early symptoms was obtained.

#### SYPHILITIC TUMOURS OF THE EYE.

Galezowski (*Recueil d'Oph.*) concludes a study of this subject thus: 1. Syphilitic tumours of the orbit are developed generally in a rapid manner, in several days or in one or two weeks. 2. They are always preceded by circum-orbital pain, very violent for several days, and by vomiting. 3. Paralysis of most or all the motor nerves of the eye is an early symptom of the affection; the optic nerve is rarely at the outset affected, but at a later period a monocular atrophy of the papilla may ensue. 4. Syphilitic periostosis and exostosis are rarely limited to a single point of the orbital cavity, but occur together with exostosis of the bones of the cranium, the legs, and arms. 5. The simultaneous occurrence with the exophthalmus of an iritis, retinitis, or choroiditis, points strongly to a syphilitic affection. 6. Tumours of the orbit occur as often in cases of heredity as of acquired syphilis.

#### NEAR SIGHT—ITS APPEARANCE AND PROGRESS.

Dr. H. Derby (*Boston Med. Jour.*) gives the following summary of our knowledge on the above subject. Near-sight is not generally found at all among children who have not commenced school life. Between the ages of six and seven some three school children in a hundred are found in this country to be near-sighted. This percentage increases steadily, and at the age of twenty at least twenty-six in a hundred are thus affected. The percentage rises to forty-two in Russia, and to sixty-two in Germany. Other things being equal, the children of near-sighted parents are more apt to acquire near-sight than are those whose parents have normal vision. The development of near-sight is furthered by the following: (a) Work by inefficient light. (b) Work on minute objects, such as fine print, intricate maps, and the like. (c) Work in a constrained or stooping position. (d) Continuous study. (e) Prolonged and excessive study. Thus Erismann found that of 4,350 scholars studying out of school hours (1) of those studying two extra hours seventeen per cent. were near-sighted; (2) of those studying four extra hours twenty-nine per cent. were near-sighted; (3) of those studying six extra hours forty per cent. were near-sighted.

## Transactions of Societies.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 12, 1881.

Dr. W. S. PLAYFAIR, President, in the Chair.

Mr. DORAN showed an

#### EXFOLIATED PORTION OF THE MUCOUS AND MUSCULAR COATS OF THE FEMALE BLADDER.

The patient, *æt.* 31, was a primipara. After seventeen hours labour a large child, weighing 18 lbs., was delivered by forceps, the bladder having been first evacuated. The perineum was ruptured, but was stitched up at once. There was difficulty in systematic use of the catheter, and cystitis appeared on the tenth day. The slough was passed on the twentieth day, and the patient afterwards did well.

Dr. GEORGE HOGGAN showed

#### MICROSCOPIC SPECIMENS AND CAMERA LUCIDA DRAWINGS, ILLUSTRATING THE COMPARATIVE ANATOMY OF THE LYMPHATICS OF THE UTERUS, BEING THE MATERIAL ACCUMULATED JOINTLY WITH HIS WIFE.

He demonstrated specially the lymphatics of the mucosa, which investigators had hitherto failed to discover. The superficial division of these ramified immediately under the epithelium. There were no true sub-serous lymphatics, but the vessels so-called were the lymphatics of the longitudinal layer of muscle on its outer surface. They appeared merely as small twigs which crop up here and there, and dip down again. In some animals—the mare—no lymphatics are ever seen on the serous aspect of the muscle. The subserous lymphatics

of the ovary were shown, that organ presenting a strong contrast to the uterus in this respect. On either surface of the circular muscles the lymphatics lay as dilated valvular sinuses, parallel to the muscular bundles, being capable of great elongation on the distension of pregnancy. The specimens were mostly prepared with silver and gold solution.

Dr. MATTHEWS DUNCAN exhibited two ovaries removed by Dr. Lediard in a case of double ovariectomy, in which there was suspicion of malignancy. A large amount of ascites had existed with the tumours.

Mr. KNOWSLEY THORNTON said that the specimens resembled one called a papilloma of the Fallopian tube, exhibited at the Pathological Society by Mr. Doran. He thought it an interesting question whether in these cases the fluid was secreted by the peritoneum, or was a secretion in the interior of the tumours which escaped by minute apertures.

Mr. DORAN mentioned other cases of ascites associated with still smaller growths, or with merely chronic inflammation of the ovaries, cured, in the latter case, by oophorectomy.

Dr. EDIS showed a simple form of syphon douche consisting of six feet of rubber tubing, with a vaginal nozzle. By inserting the tube through the spout of a bath-can, and withdrawing it partially when filled, a syphon action was at once produced.

Dr. CHAMPNEYS showed the uterus, &c., of a woman who died from septicæmia, in consequence of a rupture of the upper and posterior part of the vagina; not, however, through the peritoneum. The child, which was born at the end of the seventh month, had been dead some time, and the labour was completed with apparent ease in four hours.

Dr. WILTSHIRE mentioned a case of laceration of the left lower segment of the uterus, where the patient had been rather precipitately delivered before help arrived. She recovered.

Dr. THOMAS CHAMBERS on

#### COMPLETE EXTIRPATION OF THE UTERUS WITH BOTH OVARIES, WEIGHING 10 LBS.—RECOVERY.

Jane S., *æt.* 45, was admitted into the Chelsea Hospital for Women, May 24, 1880. In 1870 she first noticed a lump in her right groin, which grew slowly for five years. After this menorrhagia commenced, and gradually increased. Pain and hæmorrhage were excessive, and she eventually became too weak to attend as an out-patient, and was remarkably emaciated. The tumour was freely movable from side to side, and was very soft and doughy, but without fluctuation. The pelvic cavity was unoccupied, the vagina drawn up into a cone, with the os and cervix, both small, in the centre. There was a periodical discharge of watery fluid through the vagina. Hence a diagnosis of fibro-cystic tumour was made. Medical treatment having proved of no avail, extirpation of the uterus was proposed to the patient, and she decided in favour of the operation. It was performed on June 22nd. The abdominal incision was extended to eleven inches. The broad ligaments were tied with silk at each side, a parallel clamp placed above the ligatures, and the uterus cut away. After a few minutes arterial hæmorrhage occurred from a large vessel, which was at once secured. The cervix was then transfixed by a double ligature, the clamp removed, the ligatures tightened, and the stump replaced. By the 21st day the patient was convalescent, a free discharge of offensive matter from the vagina having taken place suddenly on the 14th day. The tumour proved to be a lobulated white fibroid, not fibro-cystic, and contained very large vessels.

Dr. HAYWOOD SMITH thought that the term hysterectomy should be limited to amputation of the uterus, and not applied to cases of fibroid outgrowth. He considered oophorectomy safer than removal of the uterus, where life was threatened by bleeding and pain.

Dr. ROUTH had some years ago tabulated a number of fibro-cystic tumours as compared with pure fibroids of the uterus, and had found that in fibro-cystic disease menorrhagia was rare.

Dr. ROGERS on

#### A CASE OF CHRONIC COMPLETE INVERSION OF THE UTERUS SUCCESSFULLY TREATED BY SUSTAINED ELASTIC PRESSURE.

S. B., *æt.* 29, had a child two years ago. Delivery was followed by great bleeding, and menorrhagia had continued more or less ever since. On admission a tumour was felt in the vagina as large as a turkey's egg. A ring encircled its neck, but the sound could not be passed more than a line or two above this. On April 28th Dr. Aveling's double-curved

repositor was applied and adjusted by Dr. Aveling. After twenty-four hours the strings were tightened, the patient being very comfortable. About sixteen hours later she felt great relief; something had given way, and the strings had become loose. On examination the repositor was found within the uterus high up, and was removed without difficulty. The uterus was completely restored.

Dr. AVELING stated that since he had invented his repositor last year, five cases had been successfully treated by it.

Dr. MATTHEWS DUNCAN ON

DELIVERY IN A CASE OF DOUBLE UTERUS.

The patient was delivered naturally in her ninth pregnancy, but as a portion of the chorion remained in utero, the hand was introduced into the uterus to seek for it. The uterus was then found to have two cavities, of which the child had been in the right. The left was smaller, but similarly shaped, having a rounded fundal roof. In some previous pregnancies the patient had had copious losses of blood about the third and fourth months. The cervix was single and normal.

Dr. BRAXTON HICKS ON A

CASE OF PREGNANCY WITH DOUBLE UTERUS AND VAGINA.

The author was called to examine a lady, pregnant four months, with a tumour in the right inguinal region; to ascertain whether the pregnancy was extra-uterine. On passing the vulva the finger came in contact with the edge of a firm septum, and it was obvious that an os uteri existed on either side. The uterus on the right side was manifestly pregnant, and of course more developed. Labour took place naturally at full term, and the abnormality was not noticed by the medical attendant.

Dr. MATTHEWS DUNCAN hoped that all cases of delivery with double uterus would be reported, as they would throw light on many points in the mechanism of pregnancy and labour.

SUPPLEMENT TO A PAPER ON FIBROID TUMOURS COMPLICATING DELIVERY.

By Dr. W. S. PLAYFAIR.

Two cases were detailed as a supplement to the paper by the author in the 19th volume of the "Society's Transactions." In May, 1878, the author was called upon to see a young married lady on account of severe dysmenorrhœa. She had aborted without any known cause within three months of marriage. A large lobular mass was found occupying Douglas's space, and displacing the cervix forward. It had much mobility, and was diagnosed as a fibroid. Much anxiety was felt as to probable obstruction in labour if pregnancy occurred. Soon after she did become pregnant, but the fibroid gradually rose above the brim as pregnancy advanced. Delivery took place naturally, and the fibroid afterwards diminished in size, and did not again descend into the pelvic cavity. The second patient, æt. 31, was seen first by the author, about the fourth month of pregnancy, in July, 1880. The greater part of the cavity of the pelvis was then occupied by a rounded, somewhat lobulated mass, rising above the pelvic brim. The cervix was pushed forward and upward, so as to be difficult to reach. It was decided to wait awhile, and the tumour rose to some extent, but became stationary about Nov. 8. Dr. Hicks met the author and Mr. Wells on Nov. 30, and a vain attempt was made to push up the tumour under anæsthesia. On December 1 premature labour was induced, with the intention that Mr. Wells should perform Porro's operation, if necessary. When the os was fully dilated the author made a final attempt to push up the tumour, and did so by using considerable force with the closed fist. The child was extracted by version, and was living.

THE rates of mortality last week in the twenty-three large towns of the United Kingdom averaged 29 per 1,000 of their aggregate population, which is estimated at about eight millions of persons, and were as follows:—Portsmouth 19, Edinburgh 21, Bradford 21, Birmingham 23, Hull 23, Norwich 24, Leeds 24, Bristol 24, Brighton 24, Sheffield 24, Sunderland 25, Leicester 26, London 28, Newcastle-on-Tyne 29, Oldham 31, Wolverhampton 31, Salford 32, Nottingham 32, Glasgow 35, Liverpool 35, Manchester 43, Plymouth 45, and Dublin 45.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 2, 1881.

### THE MEDICAL REFORM BILL.

THE medical reform campaign in Parliament has been fairly commenced by the introduction of the Bill which bears the names of Mr. Hardcastle, Sir Trevor Lawrence, Dr. Farquharson, and Mr. Hastings. As this measure will be issued by the Parliamentary printers in a day or two, and stands for a second reading on the 2nd of February, it is necessary for us to give something of its history. Our readers know that medical reform has, for several years past, been represented by three Bills.

a. The Government Bill, which provided for conjoint examination, and left all else as it is.

b. The Bill introduced by Messrs. Mills and Goldney on behalf of the British Medical Association, which, to the proposal for conjoint examination, added a scheme for the election of six representatives elected to the General Medical Council by the votes of the registered medical practitioners of the kingdom, the number of the Council being thus increased by six.

c. The Bill of the Medical Alliance Association, introduced by Dr. Lusk, which aimed at the same objects as the Bill of the British Medical Association, but in order to make room for the six direct representatives in the General Medical Council, reduced the existent number of that body by discontinuing the elective power of certain effete corporations, and combining the elective rights of others, so that one member should be returned by the collective votes of two or more such institutions. This Bill also aimed at a radical improvement in the law for the suppression of practice by unqualified persons.

Lastly, there was the Bill promoted in 1871 by the *Lancet*, which measure proposed a wholesale dis-

franchisement of the minor licensing bodies, and provided for many changes of an advancedly progressive character. For ten years these various legislative proposals have been before the House, the Government Bills being successively in the hands of the Marquis of Ripon, the Duke of Richmond, and now Earl Spencer. The Duke of Richmond's Bill in 1878-9, nearly achieved success; it passed its three readings in the Lords, but when it reached the Commons, the influence of the Scotch Universities, who felt that "a fair stage and no favour" would not suit their interests, was successfully exerted to delay the measure by having it referred to a Select Committee.

The sittings of the Committee were occupied in the hearing of witnesses, the great majority of whom were members of the Medical Council, and delegates from the Scotch licensing bodies, whose testimony was—in a nutshell—that the existing system was delightful, and any change objectionable. Unfortunately, before the evidence on behalf of medical reform could be fully heard, Lord Beaconsfield dissolved Parliament, and the deliberations of the Select Committee came to an end.

But medical reformers had learned a useful lesson. It had been made plain that the only chance of defeating the energetic moneyed opposition of the recalcitrant licensing bodies, and the covert hostility of the General Medical Council, lay in uniting the reform forces, and adopting one Bill as the expression of the views and aspirations of the whole profession, as contra-distinguished from the views and aspirations of the licensing bodies.

This great object has, we are gratified to say, been most satisfactorily achieved, and the Bill now submitted to the House is the embodiment of the demands of the profession upon the question of medical reform. Upon the approach of the parliamentary session, the Council of the Irish Medical Association took the initiative more towards that unity which is strength, by sending to the representatives of the Medical Reform Committee of the British Medical Association, the proprietors of the *Lancet*, the Medical Alliance Association, and the Medical Defence Association, official invitations to meet in conference, and interchange their views upon medical affairs. The invitations were accepted with a degree of alacrity, which gave gratifying proof that all parties were willing to sacrifice their individual opinions for the advancement of the reform cause. Two conferences were held in London at which the leading principles of the Bill were declared in a series of resolutions which, it is most hopeful to know, were adopted in almost all cases by a unanimous vote of the representative delegates. The distinctive features of the Bill are the following, most of them being in accordance with the policy of the Bill of the Government:—

1. That the licensing bodies of each division of the kingdom shall be obliged to conjoin in forming an examining board, through which every candidate for admission to the profession must pass.

2. That the curriculum required for such examination, the standard of the examination itself, and the fee payable, therefore, shall be equal throughout the kingdom.

3. That, in order to place the licentiate under the government of licensing bodies, he be required to obtain diplomas from the bodies co-operating in the examination,

being entitled, however, to obtain those diplomas on demand without further examination or fee.

4. That the licensing bodies shall make what regulations they please as to Fellowships, Doctorates, and other higher degrees.

5. That, out of regard to the higher degree of knowledge usually required from university students, such students be allowed to take their primary in the university if they take their final practical examination before the conjoint board.

6. That foreign and colonial diplomas be accepted for registration only if they represent a degree of knowledge equivalent to that required at home, and only from actual foreign and colonial practitioners.

7. That, to ensure the carrying of these arrangements into execution, the General Medical Council be reformed by removing from it the representative of the Apothecaries' Companies of London and Dublin, and of the Glasgow Faculty of Physicians, these bodies being considered to have no longer a just qualifying function, and by adding to it six members, to be elected by the suffrages of the registered medical practitioners throughout the kingdom.

8. That the law against the practice of the profession by unqualified persons be improved and enlarged so as to include within its grasp everyone who falsely represents himself to be licensed or registered.

Such are the chief features of this Bill and we fully believe that they are such as the Government and the House of Commons will sooner or later accept as being reasonable and consistent with perfect freedom of medical education and practice. They aim at the aggrandisement of no party or class, but at the fixing of a standard of competency for the public advantage, and nothing is asked for in the interests of the profession except where those interests run side by side with those of the public. On the other hand, these proposals, if approved by Parliament, will serve the profession and the public alike, for they will raise the social and educational position of medical men by shutting—in the public interest—the gate against half-educated and wholly-incompetent practitioners.

We ask for the provisions of the reform bill the support of medical practitioners throughout the land; not the tacit, lethargic support which is identical with toleration, but the active, earnest, and enthusiastic approval which a measure for the regeneration of the profession deserves. We are confident that our appeal will not be in vain, and we take upon ourselves to promise that, if such help and sustainment be given the medical reform conference will never weary until the Bill has received the sanction of Parliament.

#### DISSECTION DIFFICULTIES.

THE dearth of subjects, of which, earlier in the present session, considerable complaint was made, has at length attained such proportions that it has been deemed desirable to hold a conference for the discussion of measures to meet its effects in the future. To this end a meeting will take place to-morrow, February 3rd, at Middlesex Hospital; and to it all the metropolitan demonstrators of anatomy have been invited. That this assembly is likely to do

more than re-traverse ground already trodden bare, there is but little hope; and it might almost be said that there is small reason for holding such a meeting, unless it be that the more junior members of the anatomy teaching staff are not yet familiarised with the difficulties which lie in the way of an improved supply of human corpses for dissection. It will be well for them to be assured at the outset of their labours how little fruit they can be expected to bear. The dilemma they experience now has been felt before; and previously, as in the present, attempts, ending fruitlessly, have been made to secure such privileges to hospitals and medical schools as should have the effect of permanently removing the obstructions to educational work that lie in a paucity of subjects. In its existing form the law gives power of refusal to permit unclaimed bodies to go for dissection to the masters of workhouses, and to the guardians of the poor. It may be presumed that the object held in view by the projectors of the proposed meeting, is such an alteration of the law as will make the provision of unclaimed paupers compulsory on workhouse officials. In one sense, the wisest, this would appear as not only a proper, but a reasonable, demand; in such way the dead would, in a measure repay the benefits received during his life, and by the facilities his remains afforded for the study of anatomy, he would benefit the general public through whom his indigence had been succoured. Similarly, too, the recipient of hospital relief might be justly expected, in the event of his decease in hospital, to aid the institution which aided him, by affording material to its alumni. Unfortunately, however, this is a subject on which plain, practical, common-sense reasoning is expended in vain. There is incorporated into it from without a sentimental objection, or one having its origin in the religious instincts, to either of which it is impossible to offer any tangible resistance. The time will come by-and-by, when this will be so no longer; but that it is so now needs no demonstration; the history of the agitations associated with the pleas of the vaccinationist, the vivisectionist, and the cremationist abundantly testify the predominant opinion on all those points which must be considered when it is proposed to interfere in any manner with the integrity, living or dead, of the human frame. Justly enough, the anatomist urges the utter impossibility of prosecuting his studies in the absence of an adequate supply of material; and he rightly seeks for wider means of obtaining it than are open to him at present. Recognising the absolute necessity of human bodies by aid of which to teach the elements of human anatomy to medical students, the demonstrators in our schools are at a loss to supply the want of them they are suffering from; but that they will succeed in their endeavours to remedy the defective supply we are seriously doubtful. So long as popular prejudice sustains the uncontrollable horror of dissection that is felt on every hand, and particularly among the poorer uneducated classes; so long, too, as the workhouse official is empowered to withhold even unclaimed corpses, and is guided in his resolve by a sympathetic participation in the dread of the pauper himself; and so long as there shall be vested in hospital authorities no power to transfer patients who die in the wards to the dissecting-room, thus long will there be periodical

scarcities of subjects, recurring more frequently as the number of students requiring "parts" increases. The proportion of unclaimed bodies in any establishment must be subject to necessarily wide variations, and thus it happens that sometimes one, sometimes another great teaching centre, is overstocked, while others are literally starving. The facilities for transmitting bodies, moreover, from the well supplied to the impoverished are unsatisfactory, and by far too expensive, so that this means of adjusting the balance cannot be looked to with any prospect of success.

What propositions will be made at the meeting, we are, of course, unable to predict. Memorials to the Home Secretary have been tried in vain; and even admitting his willingness to aid to his utmost, there is nothing he could do, short of introducing a new Anatomy Act, that would remove the hindrances to study against which complaint is made. Such an Act as would be necessary to remove these hindrances, would, we fear, possess but little chance of passing, in a parliament that can permit the clauses of the Anti-Vivisection Act to remain in force. And even though the House itself should look with favour on a scheme for enlarging the opportunities of medical education, the force of public opinion in England would inevitably compel the rejection of a measure which proposed to invade the sanctity the masses love to associate with their dead selves. One plan has been proposed before, and it might find favour again, as a means of meeting the difficulty that presents. It consists in substituting for human bodies, in the first year of the curriculum, the bodies of animals, especially of cats and dogs, on which junior students might dissect out the chief muscles and other organs, and mark their coarser relations. The wisdom of this can be proved only by test, but it offers some chances of success, while, however, it is to be admitted, there are grave objections to the proposal. At the outset of his career, more than at any subsequent period, a student should learn the least amount possible of that which he will require at a later period to unlearn, and medical students are especially unfitted to be entrusted with what is, at best, a hazardous knowledge. It would be better, perhaps, that the first winter session they spend in the medical school should be devoted to attendance at daily demonstrations on the cadaver, and actual touch-acquaintance with osteological preparations. There is a wide field open for this method of teaching, combined, as it may very well be, with inquisitorial exercises at frequent intervals. Only a few schools in the metropolis can be said to be fully provided with classes of this description; the total relegation of first year men to them is a matter deserving serious consideration.

Much as we should wish to see some practical outcome of the meeting of demonstrators at Middlesex Hospital, we cannot be sanguine that it will be fruitful beyond suggestion.

#### POOR-LAW MEDICAL SUPERANNUATION.

WE recently, in anticipation of the general meeting of the Irish Medical Association held last week, at which this subject was discussed, referred to the difficulties which exist in the framing of practical legislation which shall be

just towards the medical officers, and, at the same time, in accordance with the rule and precedent acted upon in other departments of the public service. We have again to remind the Poor-law medical officers that it would be fatal to the hope of amending the existing state of affairs in regard to superannuation if demands were made which Government could not listen to; which boards of guardians and the members who represent their views in Parliament would unanimously resist, and which the non-medical union officers could not accept. In questions of class legislation, to the adoption or rejection of which politicians are entirely indifferent, the system which is pursued in reference to great public matters of asking a great deal more than you have any hope of receiving, and being content with very much less than you ask, is entirely inapplicable and unwise, because, if impracticable requirements be insisted on, the Government simply declines to enter upon the subject at all, and leaves the matter as it is; and it is but rarely that the class for whose benefit the legislation is proposed have influence to force a Government to touch a subject into which it is not minded to trouble itself.

Applying these considerations to the question of Poor-law medical superannuation, we find that there are three parties to be satisfied besides the doctors. In the first place, the Government, as represented by the Local Government Board, must have cause shown for disturbing the *status quo*, and for recognising the right of a new class of officers to pensions; and there will not, we believe, be any difficulty in showing such cause. It will be easy to prove, by the Parliamentary return which was voted eight months ago, upon the motion of Mr. Meldon, M.P., that in numerous cases medical officers who had completely broken down in health after very lengthened service in all hardships at miserable salaries, were refused superannuation by their boards of guardians, and left to semi-starvation. It can be proved by examination of the list of pensions now enjoyed by medical officers that boards of guardians have, as a rule, refused to grant, even in the most deserving cases, the two-thirds pension to which the law entitled the medical officers; and it can be readily shown that many medical officers whose age, irrespective of their condition of health, renders it physically impossible for them to perform their duty efficiently, are, nevertheless, obliged to continue the pretence of doing so because they are dependent on their salaries for livelihood, and dare not resign their offices in order to ask their board of guardians for a pension. Furthermore, it would not be difficult, if desired, to point to instances in which the discretion vested in the guardians was abused by them in granting pensions to medical officers who had made friends with the dominant clique in their boards, although those officers were well able for duty, and have since been engaged in arduous professional work.

We have no doubt that a case can be made on these points sufficient to satisfy the Government that a change of superannuation law is needed, and that the grant of a pension should no longer be discretionary.

But this being achieved, it becomes necessary, if possible, to disarm the opposition of the Board of Guardians, whose influence in the House of Commons is by no means to be despised. Many of these Boards, we admit, are

disposed to act justly and honourably towards their officers, but many of them, it cannot be denied, have just the contrary disposition. With a very numerous and the most noisy section of the Guardians, to talk of the just rights of their officers, or of fair dealing towards a deserving servant, is empty sentiment meaning nothing compared with the paramount necessity for saving money. These Guardians don't allow themselves to think about the starving of a doctor or the dishonour attaching to the unfair treatment of him, as long as a few pence or shillings a year can be saved to themselves and those whom they represent by turning him out penniless. There is of course no legislative method of dealing with Guardians of this class but to make them do what is just, and it is quite impossible to produce this result as long as they are allowed a discretion to grant or refuse a pension. That discretion must be taken away, but we think the Guardians may be induced to yield it up more readily if it can be shown to them that compulsory superannuation justly administered will not be materially more expensive to them than the existing discretionary system, and that the benefit to the sick-poor will more than counterbalance by the small additional outlay. We should hope that these Guardians may be got to understand that it is cheaper and wiser to get rid of a medical officer when he begins to break down, giving to him a comparatively smaller pension, and thus securing the services of a young and active medical attendant, than to keep a worn out officer in harness until he cannot possibly go a step further, and then have to superannuate him on a full two-thirds of his salary and emoluments.

Lastly, it has to be considered in the framing of a Poor-law Medical Superannuation Bill, how far it is possible to place the doctors on a common basis with the other union officers, and to suggest some common arrangement fairly applicable to the whole service. This it is not easy to do, and it is open to question whether both the medical and non-medical union officers would not fare better standing by themselves and on the merits of their own special circumstances. The medical officer does not devote his whole time to his duties, and, in his private practice, he has a great inducement to hold to his official connection with the union as long as he possibly can. Moreover, his salary and emoluments being small, he cannot prudently leave himself dependent on a pension of two-thirds of their amount, supposing him to be so lucky as to be granted the highest possible superannuation. For these reasons the medical officer, as a rule, does not seek a pension until he is absolutely incapable of work. On the other hand, the non-medical union officer receives generally salary and emoluments of such amount that two-thirds, or even one-half of it, is a fair provision for advanced life, and he can, therefore, afford to go out on a pension as soon as he passes middle age and his work becomes irksome to him. His union salary is his whole income, and, therefore, by taking a pension he sacrifices nothing more than the difference between that pension and his full emoluments, a reduction of income which he can usually content himself with as soon as his sons and daughters are off his hands. Thus it will be seen that, while the non-medical union officer would naturally desire that a Bill should pass which would enable him to retire from office at any time upon such pension as is usual in other public departments; the

average medical officer, on the other hand, would probably prefer to remain in harness to the last if only he could be secured the full two-thirds, which it is now discretionary to grant him. We do not see any insuperable difficulty in combining these aspirations in one Bill, but we are quite certain that an antagonism between these two classes of union officers will be fatal to the hopes of both. Meanwhile, it is our purpose to-day to make Poor-law medical officers understand that those who speak for them cannot, in their interest, ask anything which cannot be reasonably granted, and must not be blamed if they are unable to secure all that may be considered pleasant and satisfactory.

The following, amongst resolutions adopted by the Irish Medical Association at its last meeting, prove that the medical profession, as a whole, is willing to approach the subject of superannuation in a fair and conciliatory spirit, and we are confident that such a treatment of the matter will eventually achieve much :—

That a superannuation allowance of two-thirds of the salary and emoluments should be claimable as a matter of right, upon retirement, by all medical officers of the Poor-law Service who have served thirty years, or who have become incapable of performing their duties with efficiency by reason of old age (such age being not less than sixty years), or permanent infirmity of mind or body.

That any medical officer in the Poor-law Service not qualified as aforesaid to claim the maximal pension shall be entitled, upon retirement at any time after a period of ten years' service, to a retiring allowance of one-fortieth of his salaries and emoluments at the time of his retirement for every year served.

That the period of service of a medical officer in the Poor-law Service shall comprise all the years he held office as such, whether in one or more unions, and that his superannuation allowance shall be computed thereon, the Local Government Board having power (in the event of such officer having served in more than one union) to decide whether his pension shall be payable wholly by the union in which said officer last served, or partly by each said union proportionately, or otherwise, as the said Board shall deem expedient.

That the Committee of Council do take immediate steps to have a Bill embodying these resolutions drafted by Council, and submitted to Parliament, and that the Committee of Council are hereby authorised to accept, on behalf of this Association, the best terms obtainable, after due exertion, for a system of compulsory superannuation on the lines above laid down, or as near thereto as may be.

### THE UNIVERSITY OF EDINBURGH: ITS CURRICULUM AND EXAMINATIONS.

THERE has been for some time a growing feeling among medical men outside the professorial staff of the University, that the present arrangement of the curriculum and the examinations are neither fair to the students nor their parents. In the calendar of the University there is a carefully prepared synopsis of the classes required and expenses incurred by the student in obtaining the degrees of M.B., M.C., the total sum being stated as £105 16s., but the student who takes this statement as his guide will find himself deeply misled if he indulges in the fond hope that he knows the end of his liabilities as regards the degrees in question. Referring to the synopsis just mentioned, we find that the student is advised to begin his summer by attendance on lectures on Botany and Natural History, on his knowledge of these subjects he is not examined before the October twelvemonth of commencing his studies. The student sees eighteen long weary months

before him. Procrastinating and slovenly habits are engendered, the result being, that when he ought to be engaged in other work, he is attending a second course of either Natural History or Botany. The regulation may help to fill the class room, but there is a growing feeling against it amongst the students. But this is, by no means, all of which the student has to complain. The regulations require that anatomy lectures be attended during the first winter session, but on this subject no examination is allowed till after the third winter, the intervening time being spent in attendance on lectures on chemistry, physiology, surgery, materia medica, pathology, clinical surgery, practical chemistry, and practical materia medica. The issue of this arrangement being that two courses, sometimes three, of anatomy, are attended, a result highly favourable to the professor of anatomy, if to nobody else. For the students who begin in the summer, the examination on chemistry, botany, and natural history, might be conducted in April, for those who begin in winter, in the following October, thus allowing the anatomy examination to be held at the end of the second winter, care being taken that no two sets of examination be allowed to be passed simultaneously, a rule which would prevent students being idle when they know the delay resulting from failure. But, perhaps, the greatest grievance under which the student suffers is due to the fact that several professors are allowed to hold semi-official classes, for which extra fees are charged. These classes are not demanded by the University curriculum, but, as the professors are careful to examine on the subjects taught in them, the student soon finds that it is to his advantage to take the class which he does with the best grace possible, feeling all the time that he is the victim of a not altogether reputable system of black mail. There can be no doubt that many of the subjects taught in these classes are important to the student, and there can be no possible objection to adding them to the curriculum, but the system on which they are conducted is bad, leading to a large amount of cringing hypocrisy on the part of the student to gain the good offices of his future examiner. We are sure that if the professors were aware of the opinions expressed among students, they would at once abolish the classes, or get them recognised as part of the curriculum.

### Notes on Current Topics.

#### The Injustice of Enforced Retirement in the Army.

WE regret to learn that of the senior medical officers recently ordered to the Cape two, being on account of ill-health unable to proceed, have had to retire. Where stringent regulations exist it is no doubt a matter of great difficulty to relax in the slightest degree their action, as, if once admitted it is difficult to check elasticity. At the same time the policy of "sail or sell" bears very hardly upon officers temporarily ill, and who, were some indulgence granted them, would, in a very short time, become perfectly efficient. As matters now are, their own careers are cut off midway, and they themselves cast upon the British tax-payer.

### Our Baby Recruits.

ACCORDING to information before us, the numerical strength of a distinguished regiment of infantry at one of our largest stations is 350 rank and file, of whom 200 are boys, weakly in physique, and altogether unfit for soldiers' work. As we mentioned last week, recruits are to be watched over and periodically examined by medical officers for some three months after their enlistment. We are un-informed as to the precise object of such care and attention. Considering, however, that under the existing no-system of "unification," each succeeding examination of these boys will, in all probability be performed by a different and new medical officer, who can personally know nothing of the previous condition of those examined by him, it is difficult to perceive any really good purpose to be gained by supervision under such circumstances. We had believed that the object of medical examination of recruits was to select only those who were deemed fit to undergo drill, and showed every promise of becoming efficient soldiers. Now it would appear that those *selected* are to be looked after as so many out-patients for a considerable time before they are exposed to the rough usage of military life. The arrangement really looks so incongruous that we are almost inclined to express a hope that the delicate young things may have their flannel night-gowns carefully warmed for them before they are put to bed at night, and that their nurses are sure that hot bottles carefully wrapped up, are put at their feet. In the meantime the services of strong and hale men are much required in the ranks of our regiments now actively engaged against individually powerful and brave enemies.

### Domestic "Sanitary" Arrangements and Frost.

THE severe cold which lately prevailed has had the effect of drawing the attention of many householders to the suitability or otherwise of so-called "sanitary" arrangements in houses to conditions of climate such as we have lately experienced. Not a few of the old style of houses have suffered; but it is chiefly among the newly run up villa residences in the suburbs of all large towns that inconvenience has arisen from the effect of frost upon cisterns, gas, and pipes of all kinds connected with them. For several days the water supply has been absolutely cut off; cooking ranges have had to be disused to avoid accidents such as have happened where this precaution was not observed. Sinks, waste-pipes, &c., have been rendered useless, to the great inconvenience of families, more especially those comprising the very young. And not only have these inconveniences arisen, but expenses have been incurred considerably beyond what *Paterfamilias* had estimated for. Thus, kitchens disused at home, the greater part of the day's cooking had to be done, and paid for, at the baker's or confectioner's. Water, no longer obtainable through the domestic water-pipes had to be got from the "main" through the medium of the British workman, whose valuable time and exertions had to be pecuniarily rewarded according to his own not over modest estimate of their great worth on such an occasion.

In many instances the actual cause of these inconveniences is not so much in the nature of the arrangements

alluded to as in the very imperfect and slipshod way in which they are applied. Surely it is a point of sufficient importance in regard to public health that builders and proprietors of houses, as well as others concerned, should be held responsible that all these arrangements be properly seen to without delay. If, as there seems every reason to believe, we are entering upon a cold cycle, the necessity for this becomes the more urgent.

### The Sufferings of Our Troops in Afghanistan.

ACCORDING to a correspondent of the *United Service Gazette*, this was the state of things in November last at Chaman, a place between Quetta and Candahar:—"Not a mouthful of fodder for horses or baggage animals. The men generally on half or third rations, and on two days we had to try to eat some of our transport animals, and this with no vegetables or lime-juice, and the brackish water has made the men very sickly. When the order to advance came 200 men went sick, of which number, however, only 35 were passed as unfit, and we had to march the seventeen miles of descent over sand, without water, in the heat of the day. Most of the regimental dogs disappeared during the march. The sanitary arrangements were defective, and on the way up from Quetta no latrines were erected. The 15th Regiment has left here for India, having got only half a battalion as far as this, and they were reported by the medical authorities as quite unfit for service, having had fever badly at Kurrachee. The 98th Regiment has now only 320 men fit for service at Kurrachee, and they have only just come from Malta. The 61st Regiment, after being three days only, had 67 men in hospital, and 40 of these could not be moved. The doctors inspected the 11th Foot a few days ago, and found 332 healthy men, 90 infirm, and 165 in hospital; and this is all that remains here of 760 men that corps had at Bombay, 52 having died up to this date, and 126 being at depôt and sick. The causes of the sickness are put down to—first, the bad water, which in some places is medicinal, and purges freely when taken; secondly, to the want of proper food, vegetables, and lime-juice; thirdly, to want of proper medicines, there being none in store to issue out. The result is we are quite inefficient." Such are conditions incidental to a campaign. It is quite beyond the power of any administration so to arrange as that no hardships shall attach to military service in the field. At the same time, we can but deplore the sacrifice in health and life at which the late war in Afghanistan has been carried on.

### The Coming Meeting of the General Medical Council.

THE executive committee had a meeting the week before last, and decided to convene a meeting of the full Council which will commence on Tuesday next. We believe the business to be transacted is purely dental, and has to do chiefly to with representations made by the British Dental Association, and by Dr. Jacob, of Dublin, who have called upon the Council to erase from the Dental Register all persons who, being legally neither surgeons nor pharmacutists, have been registered upon their own declaration that they were on the 22nd of July, 1878, "in the practice of dentistry in conjunction with surgery" (or with pharmacy, as the case might be). As regards the

*soi disant* dento-surgeons there are only about eighteen of them, and their removal from the list, though great in principle, is in fact insignificant in comparison with the case of the dento-pharmacutists, who number some thousands of druggists and druggists' boys, who really never were "in the practice of dentistry" in any true sense.

As a corollary to this subject, there arises the question whether the Medical Council can legally permit these persons to amend their original declaration and come on the Dental Register without the addition of any surgical or pharmaceutical affix. One such person was so permitted, but, we believe, the precedent thus made was found to be illegal and not to be followed.

To the dental profession the questions to be debated at the coming meeting are of overwhelming interest, and we earnestly hope that no legal quibble will prevent the Medical Council from making full and complete clearance of the multitude of uneducated pretenders who—because they have illegally and improperly tried to practice dentistry in the past—are now trying to secure to themselves a legally recognised foothold amongst respectable surgeon-dentists.

#### Dr. Andrew Wood.

THIS gentleman, one of the ablest and most respected members of the General Medical Council, died suddenly on the 25th ult., on the eve of his journey to London to attend the meeting of the Council announced in our last issue. Dr. Wood had been ailing a little for the past few days, but had gone out as usual on his round of visits. While still in his carriage, he was seized with what appeared to be a serious illness, and he expired shortly after reaching his house, between one and two o'clock in the afternoon. Death was the result of a valvular rupture in the left ventricle.

Dr. Wood was the representative of the Edinburgh College of Surgeons, which body will—we predict—fail to find his equal, in power, eloquence, or astuteness. By his death the Scotch Corporation and the General Medical Council itself have—as regards the coming legislative campaign for their reformation—sustained a heavy blow and great discouragement, for he was *sans pareil* their most effective apologist and the most uncompromising opponent of conjoint examination and of the reconstruction of the General Medical Council. To him was greatly due the success of the policy of delay which for the last two years has saved the licensing bodies and the Council from reconstruction, and his death occurs just at the moment when a renewal of his services in this direction is most needed by these bodies. Although the removal of Dr. Andrew Wood brings medical reformers one step nearer their object, we are quite certain that the most earnest of that class of medico-politicians will learn of his death with heartfelt regret. A full obituary notice will be found in another column.

THE directors of the Netherlands Society of the Red Cross have officially announced that the statutes of the society do not authorise them to assist the sick and wounded in the Transvaal, the fighting going on in that country not being a war in the sense to which the regulations of the society are applicable.

#### The Control of Coroners.

CERTAIN charges have been recently made against the coroner for West Surrey. In 1878 a complaint was made to the Lord Chancellor, and again in 1880, the Surrey Sessions sent a report to the Lord Chancellor from the Superintendent of Police, which the Lord Chancellor sent to the coroner, intimating that they required an answer. Eventually, the coroner was ordered to show cause against the charges made, and on the 12th ult. the hearing took place at Westminster. Mr. Baggallay, who appeared for the magistrates, proceeded to state the charges made, which consisted of two heads—first, as to neglect or delay of inquests; and next, as to alleged irregularities in regard to the payment of charges. The Solicitor-General was heard on behalf of the coroner. As to his alleged neglect or delay of inquests, he explained it on the ground of the exercise by the coroner of his discretion. As to the pecuniary matters, he gave explanations of the alleged irregularities, and stated that in every instance the payment was eventually made. The Lord Chancellor reserved his judgment until the 26th ult.

This is the first occasion within our knowledge in which the Lord Chancellor has felt it necessary to exercise his authority over a coroner, and the example may, we hope, prove useful in other cases in which immunity from correction may have led to irregularity.

#### Inception and Duration of Menstruation.

DR. BENSENGER found from a series of 5,611 women in Moscow and the surrounding provinces that the first menstruation, on the average, began at the age of fourteen years, eight months and fifteen days. Among the upper classes it generally appeared earlier than among the lower classes. This, in the opinion of Dr. Bensenger results partly from their more favourable hygienic condition, and partly from their superior intellectual activity. Menstruation ended between the 43rd and 48th years. The average number of years during which menstruation persisted was 32. On the same subject, Schlichtling concludes, from a series of 10,522 cases in the Munich clinic, that the sixteenth year is the most common age for the first appearance of the menses in the city as well as in the country. The average duration of pregnancy is from 269-84 to 270 days. The minimum time in which a child can be developed and be viable is 236 days. The maximum duration of pregnancy is 334 days. Gestation terminating in summer continues on an average three days longer than gestation terminating in winter. Children born in summer are slightly longer and heavier than children born in winter.

#### The Eucalyptus.

It is stated with regard to the growth of the *Eucalyptus globulus* in the Campagna, that the fever which in the neighbourhood of the Tre Fontana Monastery was formerly of such a pernicious character that it proved fatal to all the eighteen friars who first attempted to plant the eucalyptus, is now of so mild a character that all thoughts of abandoning the monastery and the work have been given up. This improvement is attributed to the growth of the eucalyptus tree, of which 25,000 have been planted within the grounds of Tre Fontana.

### Sea Water in London.

THE scheme for bringing a supply of pure sea water within reach of the London householder is again before the public. Notwithstanding the unsuccessful attempts made last year to engage the sympathies of Government in favour of the project, a Bill is to be introduced during the present session, having for its object to empower a company to lay a service pipe from Lancing, eight miles west of Brighton, to near Addison Road, London. The water is to be pumped to a sufficient height at the supply source, and thence gravitate to the centres of distribution at the other end of the pipe. The proposal is one well deserving the favourable consideration of the legislature, the benefits likely to accrue from its adoption being evident enough to approve it to the mind of every medical man. Sea water is an invaluable therapeutic agent in a large class of common diseases, and any means of obtaining a regular series of such baths at a reasonable rate will meet with ready support from the profession. As a hygienic adjuvant, moreover, a supply of sea water for frequent use is of the highest service, and we should be glad to see the proposed scheme successfully carried through in the interests of Londoners generally. The difficulties we presume have been fairly estimated, and present nothing that engineering skill will not avail to overcome. The keeping the pipes clear for so long a distance will probably be the chief obstacle, but one by no means insuperable.

### Clinical Society of London.

At the Clinical Society of London on Friday night Prof. Lister took the chair for the first time after his election to the presidential office. Departing from the usual custom hitherto observed on such occasions, the new president delivered an address occupying the whole time of the meeting; but in doing so it may be said he did that which obtained most favour with the members of the Society. The subject selected by Prof. Lister was the catgut ligature, and in another part of the present number we present an abstract of the discourse. At its conclusion Mr. Jonathan Hutchinson proposed, and Mr. C. Heath seconded, a vote of thanks to the president for his valuable address, the proposal being carried by acclamation. Adverting to a suggestion made by Mr. Lister that it might perhaps be desirable to adjourn discussion on the subject of the address, Mr. Heath deprecated this at the present time, preferring rather that it should take place at some subsequent date, after opportunity had been given for trial of the plans recommended by Mr. Lister. In this he is probably right, as more benefits will be likely to accrue from a discussion on practical grounds, than could happen in the present stage of the matter, when, as Mr. Heath aptly expressed it, the whole medical profession sits at the feet of Mr. Lister, who is alone in his mastery of the question. When others have had experience of his plans it will be well to discuss his results, but not till then.

### Competitive Medicine.

FOR the modest fee of three penny stamps, the editor of the *Oracle* undertakes to reply to questions in medicine "of a strictly personal character," while "questions relating to family medicine generally are answered in the ordinary

way." In these times when constant complaints are being made against regularly qualified gentlemen, who consent to give "advice and medicine" for fourpence or sixpence "in all cases," we can hardly wonder that unqualified editors of encyclopaedian attainments, such as the editor of the *Oracle* exhibits, offer the same advantages at the same rate. The *Oracle's* chief is apparently omniscient, his lore extending to every subject, but it is on his medical knowledge alone that he places any price, the amount of remuneration he expects tallying exactly with the most modest exactments of the open dispensary doctors, viz., fourpence minus the medicine thus valued at one penny. We should add that the *Oracle* reserves the right to send in return for three stamps the curt reply "consult a doctor," but adds, by way of set-off apparently, "state age, sex, and occupation." We protest emphatically against the abominable practices evidently carried on by the editor of this weekly publication. It is an insult to medicine of the most direct kind, to pretend that a person, whatever his medical attainments, can give even three pennyworth of advice to an invisible patient, when guided simply by the latter's description of his complaint. Moreover, by the publication in its columns of what it designates "medicine," and which consists of directions for treating various diseases at home, this paper is doing such damage as is shown too often by the details of coroner's inquests and police prosecutions. There are ample subjects for a paper of question and answer to concern itself about without reducing the practice of medicine to the level of penny grabbing. It is time, indeed, that the Medical Acts Amendment became an accomplished fact.

### A Lesson from America.

THE *Detroit Lancet* has the following in its January number:—The Boston physicians have adopted as a part of their future code, the following:—"A physician should not append his name, or permit it to be appended, to certificates in laudation of speculative health resorts, health excursions, nutritive or dietetic preparations, proprietary formulæ, wines, mineral waters, beverages of real or supposed medicinal efficacy, or other medical or hygienic materials." It would greatly advance the interests of scientific medicine if all medical societies would adopt and enforce the above. The New York County Medical Society, at a late meeting, passed a law similar to the above.

### Lectures at the London College of Surgeons.

NOTICE has been given by the College of Surgeons of England that Professor Parker will commence a course of nine lectures on "The Structure of the Skeleton in the Sauropsida," on Wednesday the 2nd of February. Professor Flower will then deliver nine lectures on "The Anatomy, Physiology, and Zoology of the Cetacea," commencing on Monday, the 28th of February. Professor Butlin will deliver two lectures on "The Relation of Sarcoma to Carcinoma," on the 21st and 23rd of March. Professor Treves will deliver one lecture on "The Pathology of Scrofulous Affections of Lymphatic Glands," on the 25th of March. And in June next Professor Hutchinson and Mr. Yeo will complete the lectures for the present year, the former by the delivery of a course of six lectures on "The Laws of Inheritance in Relation to

Disease," and the latter by a course of three lectures on "The Contractile Tissues." The Hunterian oration will be delivered in the Theatre of the College, by Mr. Luther Holden, on Monday, the 14th of February next, at 3 o'clock precisely.

#### A Legal Decision under the Medical Weights and Measures Act.

At the Middlesex Sessions on Saturday last, Mr. E. J. Whittle, of Townshend Road, St. John's Wood, chemist and druggist, appealed against a conviction for having in his possession four defective minim medical measures.—The proceedings were instituted in answer to a summons taken out by Mr. F. W. Tibbey, inspector of weights and measures for Marylebone, and from his information it appeared that the four minim measures referred to were from one and a-half to two minims deficient in quantity.—On the part of the Respondent Magistrates before whom the conviction had been previously obtained, it was urged that under the recent Act it became incumbent on the part of chemists and druggists dispensing drugs to be most accurate in the quantities required, as serious consequences might otherwise ensue.—A number of medical glass engravers were called as witnesses for the respondents, and they stated that by means of the pipette there was no difficulty in making either conical or cylindrical glasses correctly, and that there ought not to be a variation of more than half a minim in fifty minims. Since the passing of the Act referred to additional precautions in marking were required, but all these witnesses stated that when marked glasses passed the inspector they presumed that they were correct. The conviction was quashed on the ground that there was no proof that the tradesman was in possession of false or unjust measures, as they were stamped by the Government inspector.

THE week before last at the Southwark Police Court a man named Wordley was summoned by the Medical Defence Association for pretending to be a registered medical practitioner. On the door were two brass plates, one of which bore the name of Dr. Harding, and the other that of Mr. Wordley. The witness who proved the case, asked for the doctor; and Mr. Wordley attended her mother, who was ill, and who died a few days afterwards. The defendant gave her a certificate of death, which the registrar refused to receive, as the defendant was not a registered medical practitioner. A light of the medical profession, Mr. G. D. Harding, M.R.C.S., of Peckham Rye, testified that he also carried on business at the defendant's house. He produced a certificate from Apothecaries' Hall, showing that the defendant was admitted as a medical practitioner on the 23rd of last month. It was therefore contended that no offence had been committed, as the defendant was a duly qualified practitioner when he attended the deceased on the 25th ult. The magistrate remarked that the evidence disclosed an illegal and disgraceful arrangement between Dr. Harding and the defendant; but on the ground stated, the summons must be dismissed. He considered, however, that the Association had acted rightly in taking these proceedings.

In the large towns last week, scarlet fever showed the largest proportional fatality in Norwich and Sunderland; whooping-cough in Leeds, Glasgow, and Nottingham; and measles in London and Salford. The death-rate from fever (principally enteric) continues below the average. Small-pox caused 44 more deaths in London and its suburban districts, 1 in Dublin, but no fatal case was recorded in any of the other large towns.

UNDER the heading of "Nurses for the Transvaal," we drew attention in our last to the inconvenience likely to arise by the sending of *lady* nurses to our troops in South Africa. Army medical men as well as soldiers much prefer the regular "orderly." We are gratified to learn that our protest has not been in vain, and that we are requested to state that the order for sending out these lady nurses has been cancelled.

NOTICE is given that the Dr. James Watson prize of the Faculty of Physicians and Surgeons of Glasgow of the value of £50, will be awarded to the author of the best essay on any subject in the department of surgery. Competition for the prize is limited to Fellows and Licentiates of the Faculty. Essays must be sent in not later than the last day of 1881.

THE following medical officers have sailed for the Cape per Royal Mail steamer *Danube*, namely, Surgeon-Major Heather, Surgeons Johnstone, Faris, Connolly, Babington, Milward, Braham, Peterkin, and Dugdale. Three officers of the Army Hospital Corps are on board the same vessel.

WITH reference to the forthcoming examination of candidates for the Naval Medical Service we observe that the delay in promulgating the Warrant so long expected by that Service, deters intending competitors from coming forward.

HIS Excellency the Lord Lieutenant of Ireland has been pleased to appoint Dr. O'Reilly, of Clones, to the Commission of the Peace for the county of Monaghan, on the recommendation of the Earl of Dartrey.

OF the 44 deaths from small-pox in London last week, 28, or two-thirds, were certified as of unvaccinated persons.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE SCOTCH VACANCY IN THE GENERAL MEDICAL COUNCIL.—Owing to the death of Dr. Andrew Wood, the post of representative of the Royal College of Surgeons of Edinburgh in the General Medical Council becomes vacant. We understand that two names are already put forward as his probable successor, Dr. Patrick Howe Watson, and Professor Spencer, both ex-presidents of the College. Of these two, Professor Spence will most probably be selected. He is one of the oldest Fellows of the College, and has always taken a most lively interest in its affairs. It is also considered that his

more than Edinburgh reputation claims from the Fellows of the College some marked recognition, which they have now in their power to bestow.

**THE FELLOWSHIP AT THE EDINBURGH COLLEGE OF SURGEONS.**—The debate on the proposed new regulations for admission to the College Fellowship has been postponed owing to the sudden death of Dr. Andrew Wood, which melancholy fact will only be formally intimated to the College at their meeting on Thursday. There will probably be an early meeting to elect his successor, and take into consideration the reforms in the admission to the Fellowship so urgently required for the credit of Edinburgh as a seat of learning.

**LECTURES ON PHYSIOLOGY AND HEALTH.**—The first of a course of lectures on "Physiology and Health" was delivered last week in the School of Domestic Economy, Edinburgh, by Dr. James. In his introductory remarks the lecturer observed that the subject was a wide one, and of universal application; but in these lectures he should endeavour, for the most part, to lay before them only such matters as should be of use from a practical point of view. Before he could do this, however, it was necessary that they should consider certain general principles, so that they might intelligently apprehend the practical deductions which should follow. Proceeding, accordingly, to endeavour to convey a general idea of what was meant by the study of physiology and health, he entered into a comparison of the animal body with a machine, noting the points of resemblance and the points of difference, as exhibited respectively in the physical and vital properties of the body. The course he proposed to follow in these lectures was also sketched and the lecture was concluded with a few remarks on the modifiability of the animal body to surrounding conditions.

**VITAL STATISTICS OF SCOTLAND.**—From the official returns of the Registrar-general in the eight principal towns of Scotland for the week ending Saturday, January 22nd. we learn that the rates of mortality had risen, owing to the severity of the weather, to 31.1 per 1,000 of estimated population. This rate is 9.4 above that for the corresponding week of last year, and 6.5 above that for the previous week of the present year. The lowest mortality was recorded in Edinburgh, viz., 21.4 per thousand; and the highest in Paisley, viz., 38.1 per thousand. The mortality from the seven most familiar zymotic diseases was at the rate of 4.2 per thousand, being a slight increase on the rate for the previous week. Acute diseases of the chest caused 807 deaths, or 116 more than for the previous week. The increase in these diseases occurred chiefly in Glasgow and in Dundee, being 94 in the former and 17 in the latter town. The mean temperature was 21.7, being 2.2 below that for the week immediately preceding, and 11.9 below that for the corresponding week of 1880.

**THE LORD ADVOCATE AND THE PUBLIC MEDICAL SERVICE.**—We had occasion recently to refer in the most pointed manner to the unsatisfactory relationship of the Scotch parochial and public health officers to the authorities. We then indicated the belief, based upon private information, that the Lord Advocate was disposed to legislate in this direction. We are glad to notice that on the 25th ult. a deputation representing the parochial boards of St. Cuthbert's and the City Parish of Edinburgh, waited upon the Lord Advocate, and urged upon his Lordship the desirability of Scotland being put upon the same footing as England and Ireland with respect to medical relief grants from the Exchequer. In reply to the deputation, his Lordship said that though he did not like to express any definite opinion on the subject, he did not anticipate, provided the assent of the Scotch members could be obtained, to giving

Government the control which the parochial boards thought reasonable in regard to the fixing of the salaries and the power of dismissal of medical officers, that there would be much difficulty on the subject. We beg to urge on the profession the opportuneness of the present time, for the purpose of memorialising the Crown on this matter, and we are satisfied that with very little trouble a weighty representation from the profession would at once be forthcoming.

#### BRITISH MEDICAL ASSOCIATION (DUBLIN BRANCH).

##### NOTIFICATION OF INFECTIVE DISEASE.

The annual meeting of this branch was held on Thursday last, under the presidency of Dr. Robert MacDonnell, in the Kings and Queens' College of Physicians.

The report was devoted chiefly to a history of the movement in favour of compulsory notification of infective disease in Dublin, which movement has resulted in the introduction by Mr. E. D. Gray of the Bill to which we have already so fully referred, which compels the physician attending to certify, under a penalty of £5, the existence of infective disease. The concluding words of the report on this subject are as follows:—

"So far, therefore, your Council in endeavouring, as directed by the branch, to promote the attainment of the compulsory notification of infectious diseases, have succeeded in getting the subject brought under the notice of the Legislature, supported by influential lay and professional opinion in favour of the principle of the measure. As regards the important questions of detail that must be provided for in any Act that is put forward, there must be naturally a considerable difference of opinion. But the hon. member for Carlow has stated his willingness to receive suggestions from the Council of the branch when the Bill comes to be considered. And your outgoing Council doubt not but that their successors, whom you shall elect this day, will watch the interests of the members of the branch, as those retiring have endeavoured to do during their period of office."

We respectfully invite the special attention of the Council of the branch to the "important questions of detail" herein referred to, one of which—indeed, the chief feature of the Bill—is above referred to by us; and we submit that the British Medical Association will incur a heavy responsibility to the profession if it allows the Dublin Corporation to use the authority of the Dublin branch to force upon Irish physicians a duty so irreconcilable with their functions and their interests.

In the presidential address, delivered by Dr. MacDonnell, this subject was again dealt with at length. He trusted that the introducer of the Compulsory Notification Bill might "persevere and prosper in the work." With reference, however, to the attempt of the introducer to force this duty of notification on the physician, Dr. MacDonnell said:—

"I hesitate to support this clause, not on the ground of any breach of confidence on my part were I to carry it out, but because I doubt if it be the best method of attaining the object in view.

"It is also open to doubt whether the proposal would work well which requires that the medical attendant shall give notice to the master of the house, and on such notice the householder shall be required to communicate with the sanitary authority. Both of these propositions throw directly on the medical attendant the onus of taking the initiative.

"I am disposed to think that it would be a just, as well as a wiser, course to throw on the householder the prime initial step. It is not unreasonable to say that every householder having on his premises an individual attacked by an infectious disease is bound, by his duty towards his fellow-men, to prevent the spread of that disease. I should consider it to be his duty to ascertain from the medical attendant whether the disease was infectious; and I should require him to give notice, so that every precaution might be adopted against its spread.

"This might be accomplished by making every householder liable to indictment if disease were known to exist on his premises, but on obtaining a certificate from the medical attendant that the disease was not infectious, the indictment should be withdrawn."

We would venture to ask the learned President whether this suggestion is not the very one put forward by Dr. Jacob at the conference of the Dublin Corporation with members of the profession, as being the system most successfully worked at Greenock, and whether the President did not then declare the suggestion to be altogether impracticable, and unworthy of attention?

The meeting at which this Report was read, and the presidential address delivered, was obviously not a fitting occasion to discuss at length the propriety of giving even an apparent support to Mr. Gray's proposal, but enough was said, by subsequent speakers, in the moving and seconding of formal votes to show that a strong feeling exists amongst certain most influential members of the branch against even tolerating the imposition upon the physician of the duty of notifying infective disease. It is to be regretted that the pronouncements of the Council, and its president, instead of giving prominence to this feeling, left rather the impression that the British Medical Association approves of Mr. Gray's Bill in its principle, and regards the immolation of the physician on the altar of sanitation as an unimportant detail.

The daily papers certainly took this view of the attitude of the branch, for they exhausted themselves the next morning in a chorus of congratulation that the system of notifying disease by the physician was almost a *fait accompli*.

We shall see.

The annual dinner of the branch, given on the evening of the same day, was an entire success—largely and influentially attended, and admirably arranged. The chair was occupied by Dr. Thomas Hayden, the newly-elected President of the branch; and the toasts, which were commendably few, were spoken to by the Presidents of both the Irish Colleges, by the President of the Irish Medical Association, by Lord Rathdonnell, and other orators of distinction. The services rendered by Dr. Duffey to the branch as its hon. sec. were most deservedly the theme of several of the speakers; and we gladly unite in congratulating Dr. Duffey upon the success which has attended his efforts both as an executive officer and an *entrepreneur*.

## Obituary.

ANDREW WOOD, M.D., LL.D., Edin. and Cantab.,  
F.R.C.S. Ed., F.R.S.E., &c.

THE death of Dr. Andrew Wood has cast a dark shadow over the social and professional circles of Edinburgh, and the medical profession in Scotland has lost a representative man, for whose place it will not be easy to find a fitting successor. Dr. Wood was a staunch supporter of the Scotch corporations, and was ready to do battle in their behalf. Whether his views on the subject were always sound, may, perhaps, admit of doubt, but no one will deny that in his advocacy of them, Dr. Wood was thoroughly sincere and honest, and his death, at this time, cannot be looked upon in any other light than as a disaster by those who have a rooted and conscientious abhorrence of the one-portal system. From the foundation of the General Council of Medical Education in 1858, he represented the Edinburgh College of Surgeons in that body, and always took an active part in its deliberations; in fact, Dr. Wood was one of its most prominent and active members as chairman of the business committee, and was always listened to with respect and attention.

Born in 1809, he was the eldest son of the late Mr. William Wood, a well-known surgeon in Edinburgh. He was educated at the High School, which has the honour of having been the literary oradle of more than one distinguished man. Passing thence to the University, he graduated there at the age of twenty-one, and in 1831 he became a Fellow of the College of Surgeons, and in 1855 was elected President of that body. In 1851 he took an active part with Professor Struthers, of Aberdeen, in obtaining the present charter of the College, and in preparing the regulations with regard to the admission to the Fellowship, which regulations, had he lived, we believe he was prepared to modify considerably, and to side with those who are now endeavouring to introduce a system of examination as preparatory to admission to that honour. It was not alone, within the somewhat narrow precincts of professional life, that Dr. Wood was known, for literature may also claim him as one of her most ardent ad-

mirers and workers, for amidst the busy routine of daily practice, he found time to devote himself to the translation of several works from ancient and modern classical writers. He was an excellent linguist, and a good classical scholar. His first volume of translations was the "Satires of Horace," published in 1870, followed two years later by the "Epistles and Art of Poetry," by the same writer. From the German he translated into blank verse, Schiller's "Don Carlos," and Lessing's "Nathan the Wise," his last work in that direction being Schiller's "Lay of the Bell, and other Ballads." We believe that many of these translations were made in his carriage when on his daily rounds. If, in all cases, he did not quite catch the spirit of the original, which can equally be said of more pretentious attempts, yet Dr. Wood's translations will always be read with pleasure, and admired for the elegance which marked many of his reproductions. Dr. Wood was a man of great force of character and robust physique, and no one who saw him in his accustomed seat on the front bench to the right of the President, at the last meeting of the College, would have dreamt that he was so soon to be taken away. His activity and vigour were so marked that they formed the refrain of a song sang at the College dinner two years ago, and composed by his friend, Dr. Gillespie, in which he was playfully described as the Mercury of the College, the "Flying Scotchman, Dr. Andrew Wood."

In support of his opinions he always spoke in a dignified and courteous manner, and with considerable oratorical power, and to these qualities may be attributed the success which attended his advocacy of those points which he held to be of advantage to his College and to the profession at large. That his worth was not permitted to pass unrecognized may be inferred from the fact that the University of Edinburgh in 1879 conferred on him the honorary degree of LL.D., and at the meeting of the British Medical Association at Cambridge in 1880, a like honour was conferred on him by that ancient University. He was a Fellow of the Royal Society of Edinburgh, Inspector of Anatomy for Scotland, and Physician to George Heriot's Hospital since the year 1858, to which institution he rendered signal service during severe epidemics of small-pox, and other diseases, which during that period raged in Edinburgh.

On the day of his death he was engaged as usual in visiting his patients, the last place at which he stopped before going home being Messrs. MacLachlan and Stewart's, where he was in the habit of calling almost daily. On getting into his carriage he requested his coachman to drive home, and on his arrival the coachman, noticing that he did not leave his carriage as usual, suspected that something was wrong, and on going to the carriage door found him reclining in one corner of the vehicle with his hat off. With the assistance of his son Dr. Wood was removed into his study, where he was soon after seen by Sir Robert Christison and Dr. Haldane, but no assistance could be rendered, and he died half-an-hour afterwards without regaining consciousness. The cause of his death was a very small valvular rupture in the left ventricle of the heart, covered by a clot of blood, which had prevented a further escape of blood, and allowed life to be prolonged longer than would otherwise have been the case. Dr. Wood leaves a widow, five sons, and a daughter. His fourth son, Dr. Russell Wood, who returned about a year ago from the Zulu war, and has since been assisting his father, will succeed to the practice. Dr. Wood was interred last Friday in Warriston Cemetery. The funeral was strictly private, being only attended by his relatives, the heads of the Colleges, and a few of his more intimate friends.

## Medical News.

Royal College of Physicians of London.—The following gentlemen having passed the required examination were admitted members on January 27th:—

Beale, E. C., M.B., Cambridge, 16 Langham St., W.  
Saunders, C. E., M.D., Aber., 21 Lower Seymour St., W.  
Willis, W., M.D., Edinburgh, 166 Stanhope St., N.W.

Royal College of Surgeons of England.—The following candidates having passed the required examination received the diploma of M.R.C.S. at a meeting of the Court of Examiners on 20th January:—

Charles Ernest Ashton, Alfred Bolton, James Bear Branch, L.S.A.

Oscar William Clark, George William Collins, Walter Cooper, L.S.A.; Herbert Maxwell Curtaene, William Coulter Falls, John William Inger, Ernest Craven Lunn, L.S.A.; John Mason, Robert Bradley Roe, Reuter Emerick Roth, Arthur Samuel Stokes, John Thomas, L.R.C.P. Lond.; John Arthur Webster.

The following passed on January 21st:—

C. A. A. Alexander, B.A. Cantab.; Thomas Renel Atkinson, Henry Beattie, Arthur Edward Boot, Christopher Duffield Briggs, James Blackburn Brooks, Charles Edward Brunton, George Tucker Clapp, Charles Fillingham Coxwell, B.A. Cantab.; Charles Daniel Davis, William Eckett Fielden, Underwood Arthur C. Harrie, Herbert Byfield Hawksworth, Edwin Hermus Holthouse, B.A. Cantab.; Thomas Wm. Carnall Jones, Thomas Macon King, Robert Edward Rygate, John Edward Squire, Stanley Temple Thomas, Ferdinand Broër Mathiew Währnits.

The following passed on January 24th:—

James Barrington Baker, Herbert Clatworthy, L.S.A.; Charles William Glassington, Daw Astley Greswell, James Harper, George Lindsey Johnson, M.A. Cantab.; George Ryding Marsh, George Anderson Meaden, Frank Newcombe, L.S.A.; William John Nicholls, John Lewis Bagnall Oakley, Alfred Orchard, George Toms Revell, Bernard Scott, Edwin Alfred Starling, Benjamin Studer, L.S.A.; Samuel Walter Sutton, L.R.C.P. Lond.; Frederic Ernest Taylor, Charles Robert Tyrrell, Lawrence Thomas Ward.

The following passed on January 25th:—

Robert Brookes, Walter Gripper, M.B. & B.A. Cantab.; Walter Johnston, George Augustus Macnutt, John Irwin Palmer, Gilbert Thomas Smith, Solomon George Watson.

The following passed on January 26th:—

Edward James Biden, L.S.A.; Charles Crossley, L.R.C.P. Edin.; Charles Haagar Downes, L.S.A.; Edgar Fyvie, L.S.A.; Arthur Kidd, William Henrige Lerge, L.S.A.; William Henry Phillips Lewis, Arthur G. Sulleman Mahomed, L.S.A.; James Macdonald Rogers, L.S.A.; Henry Smith, L.S.A.; Charles Watts Whistler.

Of the 168 candidates admitted to examination during the past fortnight, 99 passed to the satisfaction of the Court and obtained their diplomas; 10 passed in Surgery, and when qualified in Medicine will be admitted members; the remaining 59 failed to reach the required standard, and were referred for six months' further professional study. Two candidates who had passed in Surgery at previous examinations, having subsequently obtained a medical qualification recognised by the College, were also admitted members.

College of Physicians in Ireland.—At the January examinations the following obtained the licence in Medicine and Midwifery of the College:—

**MEDICINE**—Humphry John Broomfield.  
**MIDWIFERY**—Robert Samuels Archer, Humphrey John Broomfield, Nicholas John Halpin (Surgeon, Bengal Army).

The undermentioned Licentiates have been admitted members:—

James Berry Kenny, Alex. Lane, George Lyndon, Hugh Warnock.

Royal College of Surgeons in Ireland.—At the examination in general education held on the 19th January, the following gentlemen were adjudged certificates of qualification, the names in the First and Second Classes being arranged in order of Merit:—

**FIRST CLASS**.—Timothy Egan, Thomas George Drake, Louis Albert Frederick Bate, Frederick Wm. Allwright, Henry Walter Humphries, James Williamson Patrick, Richard Lonsford Fitzgerald, Clement Curt Hennig, Edward James O'Connor, Frederick Duncan Lawson, and Jeremiah Joseph Behan.

**SECOND CLASS**.—Joseph O'Connor, William Frederick Graves, Alexander Thompson Drake, Frederic Robert Blakey, Martin Fennelly, Thomas Bodkin Costello, and Thomas Mangau.

**UNCLASSED**.—Thomas Fergus Borke, James Cahill, James Anderson Flanagan, Charles Joseph Geoghegan, Graham Kennedy, Henry Keagge, Patrick Smith McAuly, Richard Knight Rainford, Hamilton James Thornbury, Thomas Francis Wyse, and John Francis Yeates.

## NOTICES TO CORRESPONDENTS.

**LOCAL REPORTS AND NEWS**.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

**SPECIAL NOTICE TO SUBSCRIBERS**.—The Publishers respectfully remind subscribers that subscriptions for the past year are now due, and should be remitted for England and Colonies to the London office, for Ireland to the Dublin office, and for Scotland to the Edinburgh office.

**Dr. J. ADAMS ALLEN, Chicago**.—Our publisher informs us that the address was duly altered on receipt of note about a month since; we have communicated with the postal authorities as to the cause of delay.

**Dr. BRICE, Dr. BROADBENT, and Mr. H. V. WOOD (Thetford)**, will please receive our thanks.

**Dr. COOZWELL (Cincinnati)**.—With pleasure.

**LAST WEEK'S WRACKER**.—As a corollary to the immense loss of life

and property during the month of January, we may add that there were 81 British and foreign wrecks, of which 20 were British, reported during last week, making a total of 260 for the present year, or an increase of 137 as compared with the corresponding period of last year. The approximate value of property lost was £5,200,000, including British £3,200,000. Twelve vessels were lost off the coasts of the United Kingdom.

**PROF. HELMHOLTZ**.—Admirers of this celebrated scientist will shortly have an opportunity of hearing him lecture. The Faraday Lecture, which is delivered annually, will this year be in the hands of Prof. Helmholtz in the theatre of the Royal Institution on Tuesday, April 5. The subject will be "The Modern Development of Faraday's Conception of Electricity." The lecture will be delivered in English.

**FRIDEMIOLOGICAL SOCIETY**.—Wednesday, Feb. 2, at 8 p.m., Dr. Squire, "On Instructions for Vaccine Inoculation."—Surgeon-General C. A. Gordon, "On certain Considerations regarding Cholera and Fever, more especially with reference to India and China."

**OBSTETRICAL SOCIETY OF LONDON**.—Wednesday, Feb. 2, at 8 p.m., Annual Meeting; Election of Officers and Council, President's Address, and other communications.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND**.—Wednesday, Feb. 2, at 4 p.m., Prof. W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

**HARVEIAN SOCIETY OF LONDON**.—Thursday, Feb. 3, at 8.30, "A Case of Temporary Hemiplegia after Localised Convulsion," by Dr. Hughlings Jackson.—"Types of Imbecility," by Dr. Fletcher Beach.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND**.—Friday, Feb. 4, at 4 p.m., Prof. W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

**ODONTOLOGICAL SOCIETY OF GREAT BRITAIN**.—Feb. 7, Ordinary Meeting.—President's Address.—Casual communications from Mr. A. Coleman, Mr. Percy May, and Mr. F. Canton.

## VACANCIES.

**Ballinrobe Union**.—Medical Officer for the Ballinrobe Dispensary District.—Salary, £100, with £25 additional as Medical Officer of Health. Applications by Feb. 10. (See Advt.)

**Hackney Union**.—Medical Officer for the Fifth District. Salary, £80, with the usual extra fees. Applications to the Clerk's Office, Hackney Union, Homerton, E., by Feb. 8.

**Oldham Infirmary**.—House Surgeon. Salary, £80, with board, &c. Applications to the Hon. Sec. before Feb. 9.

**Richmond District Lunatic Asylum**.—Assistant Medical Superintendent. Salary, £130, with other allowances valued at £84 per annum. (See Advt.)

**Royton Union**.—Medical Officer of Health. Salary, £100. Applications to the Clerk of the Guardians before Feb. 8.

## APPOINTMENTS.

**CONNER, J., B.M. & M.S.**, Medical Officer to the Corfe District of the Taunton Union.

**DAVIS-COLLEY, J. N. C., M.B., M.C., F.R.C.S.E.**, Surgeon to Guy's Hospital.

**DINWELLY, W. T., L.K.Q.C.P.I., M.R.C.S.E.**, Honorary Surgeon to the Flintshire Dispensary, Holywell.

**DITCHETT, W. E., M.R.C.S.E.**, Medical Officer to the Louth District and the Workhouse of the Louth Union.

**FAGGE, C. Hilton, M.D., F.R.C.P.**, Physician to Guy's Hospital.

**FARMER, E. W. W., M.R.C.S.E.**, Resident Medical Officer to the Seamen's Infirmary and Royal Dispensary, Ramsgate.

**FINLAY, D. W., M.D., C.M., M.R.C.P.L.**, Lecturer on Forensic Medicine at the Middlesex Hospital School of Medicine.

**FLACK, J., L.R.C.P., M.R.C.S.E.**, Medical Officer to the City of London Lying-in Hospital, for the Bethnal Green District.

**GILBOY, J., L.F.P. & S., L.M.**, Parochial Medical Officer and Vaccinator for the Parish of Middleborough, Dumfriesshire.

**HIBONS, G. M., L.R.C.P. Ed., L.R.C.S. Ed.**, Honorary Surgeon to the Bournemouth General Dispensary.

**LOVE, A. E. B., M.R.C.S.E.**, Honorary Surgeon to the Bournemouth General Dispensary.

**LUDWIG, G., M.D., M.R.C.P.**, Honorary Assistant Physician to the German Hospital, Dalston.

**OxLEY, Mr. H. R.**, House Physician at the London Hospital.

**ROBERTS, E., L.R.C.P. Ed., L.F.P.S.G.**, Medical Officer to the Llanfair-talhaiarn District of the St. Asaph Union.

**TOWNLEY, A. T., L.F.P.S.G.**, Medical Officer of Health for the Oswaldtwistle Urban Sanitary District.

## Births.

**MEADOWS**.—Jan. 26, at Otley, Ipswich, the wife of F. W. Meadows, M.R.C.S.E., of a daughter.

## Marriages.

**THOMAS-SEDGWICK**.—Jan. 27, at Christ Church, Lancaster Gate, Percy Williams Thomas, Esq., of 30 Emperor's Gate, South Kensington, to Amy, daughter of Leonard W. Sedgwick, M.D., of 2 Gloucester Terrace, Hyde Park, W.

## Deaths.

**CLIFTON**.—Jan. 21, at Cross Street, Islington, Nathaniel Henry Clifton, F.R.C.S.E., aged 63.

**GREGG**.—Jan. 17, at Institution Road, Elgin, Robert Gregor, M.D., aged 60.

**TRIBE**.—Jan. 26, at Higham, Kent, Elizabeth Anne Tribe, second daughter of the late B. Tribe, F.R.C.S., of Chatham.

**WOOD**.—Jan. 25, at his residence, Darnaway Street, Edinburgh, suddenly, Andrew Wood, M.D., F.R.C.S. Ed.

# PETER MÖLLER'S COD-LIVER OIL.

## PETER MÖLLER,

*Knight of the Orders of "Vasa" and "St. Olaf;" Corresponding Member of "La Société de la Pharmacie à Paris;" Member Elect of the Royal Philosophical Society of Drontheim; Honorary Member of the Medical Society of Stockholm, &c.*

Author of the Pharmaceutical Section of the "Pharmacopœia Norvegica" (Christiania 1874).

Offices—CHRISTIANIA, NORWAY, & 521 OXFORD STREET, LONDON, W.C.  
Manufactories—LOFOTEN ISLANDS.

THROUGH the scientific researches of Otto Naumann (*Archiv. d. Histkunde.*) & by some light has been thrown upon the peculiar properties of Cod-liver Oil as a medicine, and it has been shown that these intrinsic peculiarities are unshared to the same extent by any other adipose matter. Through his researches it has been demonstrated that this Oil is endowed with more readiness to assimilate with the organism, and greater susceptibility of oxidation than any other kind of oil or fatty substance; hence the failure of the many attempts, chiefly prompted by mercantile speculations, to substitute other remedies. But although Cod-liver Oil, as a whole, is unique in regard to these properties, different varieties present marked distinctions, and herein the locality exerts the greatest influence. The shoals of Cod that frequent one fishing ground are not found in another, each place having, as it were, its own rather large family, which, from reasons peculiar to that spot, return at regular intervals, and are, sooner or later, caught. Thus, it appears that each family has been assigned a separate habitat in the ocean, the food provided by Nature for one being quite different to the natural provision for the other.

The three chief sources of production of Cod-liver Oil are Newfoundland, Finmark, and Lofoten, each with its own separate family. Of these, the Newfoundland Cod lives chiefly upon the caplan (*walotus arifous*), as does also the fish caught at Finmark, in Norway; and it is a curious fact that the Oils produced at these two fishing places present so many similarities that they are not to be distinguished one from the other. The Lofoten fish, on the contrary, feed entirely upon the crustaceans of the deep sea; they come once a year into the shallow waters of Lofoten for the sole purpose of spawning, and again migrate as soon as the instinct of propagation has been accomplished, which is not the case at any other fishing place in the world.

Now, when it is considered, firstly, how totally different is the food upon which the Lofoten Cod lives; then, again, the physiological constitution of the animal when taken, viz., immediately before or after the deposit and fecundation of the ova—a period during which the organism experiences such a violent revolution in its normal action—it would be an astonishing fact could no dissimilarity be detected between the Lofoten Oil and other oils. But such dissimilarity does exist, and in a marked degree. The Lofoten Oil is fatter; it contains less stearine and palmitine, has greater consistence than the other two Oils, and a remarkably higher affinity for oxygen.

Before Peter Möller introduced his method of preparing Cod-liver Oil, the Lofoten Oil had already gained a wide reputation as a far more powerful remedy than oils from other sources; the crude way, however, in which it was prepared, and the consequent nauseous flavour was always its great drawback. To obviate this objection, he introduced the improved process which is now identified with his name. As, however, this new Oil had, in outward appearance, more similarity to the less efficacious Newfoundland Oil than to the dark Lofoten Oil as then known, its virtues were (and still are) mistrusted because not properly tested. As a proof of the fallacy of such mistrust, it will be sufficient to adduce only the testimony of an authority, whose high standing no one will question—the Medical Society of Norway. At one of its meetings the subject was thoroughly ventilated, and the following is an extract of the minutes.

Christiania, January 30th, 1868.

"The Norwegian Medical Society having received an application relative to the medicinal use of Pale Cod-Liver Oil prepared by PETER MÖLLER'S process, the subject was duly discussed at the meeting of the Society held on the 15th of January last. Professors CHE. BORCK, HEIBERG, VOSS, LUCHMANN, the President of the Society, and several other members took part in the discussion. From the information supplied and authenticated on that occasion, it may be laid down as a fully substantiated fact that the physicians to the hospitals and the public generally in this city rarely, if ever, prescribe the brown oils, and when they do so, from economical reasons alone, having a decided preference for the pale oil obtained by MR. PETER MÖLLER'S mode of preparation, the latter having been proved by experience to be equally powerful in its therapeutic action, far less nauseous, and

much easier of digestion. Several officially appointed practitioners who attended the meeting gave evidence to the effect that this variety of pale oil, though more expensive, is administered even to pauper patients, on account of its singularly beneficial and salutary properties."

"OTTO LUND, President.  
"A. HOLST, Hon. Secretary."

When a body of gentlemen of such high professional repute are so unanimous in their opinion, as in this instance, it is but reasonable to attach some importance to their views, more especially when it is considered that probably no other country in the world affords such numerous and favourable opportunities as Norway for practically testing on an extensive scale the relative superiority of different kinds of Cod-liver Oil, and it must be remembered that in the whole materia medica there is not another remedy that may, with impunity, be adulterated to such a degree as this.

As is usually the case when "success succeeds," a host of manufacturers have sprung up, all working, more or less, in accordance with the ideas conceived by Peter Möller, and so patent are the advantages of his process, that his method is, now, imperfectly used by every maker in Norway, however much they profess to employ—as it generally runs—"an entirely new process." But that they are only imitators, and that Peter Möller has, through practical experience during nearly thirty years kept the lead by the constant addition of improvements, combined with careful study and personal superintendence may be concluded from the fact that for twenty years MÖLLER'S OIL has at all International Exhibitions been compared with the best make of other manufacturers, and invariably declared the only perfect Oil—a success not attained by any other manufacturer.

When in a single instance an article has been distinguished by a superior award it may be suspected that not merit alone has induced the decision of the Jury; but when such distinction follows again and again, awarded each time by a distinctly different Jury of the chief experts, it is only reasonable to conclude that the exhibit has been judged by its merits and those alone. Thus MÖLLER'S Cod-liver Oil obtained the first prizes at the Exhibitions:—London 1864, Bergen 1865, Stockholm 1866, Paris 1867, Naples 1871, Christiania 1871, Copenhagen 1872, Moscow 1872, Vienna (two medals) 1873, Drammen 1873, Philadelphia 1876, Paris 1876, Berlin 1880.

These awards have naturally drawn the attention of those interested to the Lofoten Oil and through it Norwegian oil generally has gained a celebrity it by no means fully deserves, because the Lofoten Oil is, as already explained, distinctly different from all other Norwegian oil: much (or rather most) of the Norwegian, and even the so-called Lofoten Oil in the market has never seen Lofoten, but is a poorer oil manufactured chiefly in Finmark; it is as identical as can be with the Newfoundland oil, and contains a large quantity of stearine, which however carefully removed by pressure at low temperatures, to give an outward resemblance to Lofoten Oil leaves it as poor as ever. The adulteration practised is of far more potent consideration than anything else, because it can be indulged in to an unexpected extent with impunity as there are no chemical tests by which most of the adulterations can be proved. They consist in the addition to the pure oil of that from the livers of nearly related species of the Cod—such as *Gadus virens*, *G. Anglufrus*, *Melca vulgaris*, *M. byrkclange*, *Merluccius vulgus*, *Brosimius broome*, and particularly *Scymnus (Squalus) borealis*. These are caught all the year round off the coast of Norway, and the produce of their livers added to the pure Cod-liver Oil. A very singular fact, peculiar to Lofoten, and one that places that Oil above suspicion, is that all other fish disappear from those waters when in the fishing season the immense shoals of Cod approach; therefore it is impossible to make any but pure Cod-liver Oil at that place and time. In many, of course, be afterwards adulterated as much as other Oil, and there can be no guarantee against this except in the name and reputation of the manufacturer.

When other makers in despair of their product approaching to the perfectness of MÖLLER'S Oil mix it with other substances—fruit ethers, highly flavoured oils, or emulsive ingredients, it shows that their product, however perfect they may call it, has not reached the standard of MÖLLER'S, but needs a corrective to hide its imperfections.

## CLINICAL LECTURES

ON

### INFANTILE PARALYSIS, AND ACUTE ANTERIOR POLIO-MYELITIS IN ADULTS. (a)

By THOMAS BUZZARD, M.D., F.R.C.P.,

LECTURE I.—(Concluded.)

It was formerly supposed that the hemiplegic form of infantile paralysis never occurred, and that the disease could, in some cases, by this means alone be distinguished from paralysis of cerebral origin. This is, however, not the case. We have here an example of the hemiplegic form:—

CASE III.—Arthur P., *æt.* 4, was admitted into the hospital on October 27, 1880, on account of partial paralysis in the left leg and arm.

From notes taken by Dr. Beevor, it appears that the family history and the previous health of the boy were good. When he was 15 months old his mother left him one morning quite well, but in the evening found that he had lost power in the left arm and leg. He had no cold upon him at the time. No other limb was affected. For three weeks after this he was quite powerless in the arm and leg. He then gradually improved till he became as he is now. He is a healthy-looking boy; the face is not affected, and the tongue is protruded straight. There seems to be nothing now wrong with the left arm, which is about equal in size and power of grasp to the right.

The left leg is rather smaller than the right, and he walks and runs rather lame with it. He can flex the hip-joint and extend the knee-joint fairly, but not so well as on the right side.

The patellar tendon reflex is normal on the right side, absent on the left. When we come to seek an explanation of this absence, we find that the faradaic excitability of the vastus internus is lower in the left than in the

(a) Delivered at the National Hospital for the Paralyzed and Epileptic.

right thigh. On the sound side, the rheophore being placed at the motor point, an induced current marked 19 on the scale causes contraction of the muscle. On the left side it needs a current of 17 to produce a like result. (The current scale is graduated from 1 to 30—1 being the strongest power.)

There is no affection of sensibility, nor of the rectum or bladder. The right calf measures  $8\frac{1}{2}$  inches; the left, 8 inches. The right thigh, 4" above patella,  $10\frac{1}{2}$  inches; left,  $9\frac{1}{2}$  inches.

The wasting appears to be in the anterior muscles of the thigh almost exclusively, and the feebleness is in the power of extending the leg.

The treatment of his case consisted in the administration of cod-liver oil. No electrical treatment was applied.

The amount of recovery in this case is in striking contrast with that observed in the following one, which illustrates one of the most formidable results of the disease that is met with. It is interesting to note that after so long an interval as thirteen years since the attack there are still some muscular fibres in one of his paralysed limbs which show a slight reaction to interruption of the constant current, a proof that the contractile element has not entirely disappeared.

CASE IV.—(Lately in the hospital). Ernest T., *æt.* 14, was admitted on Jan. 3, 1879, on account of paralysis of all four extremities. It seemed that when he was a year old, and in perfectly good health, symptoms of paralysis were noticed. No cause was known. The patient had no fit. He had never walked. He is a pale-faced lad who is not able to raise himself from the recumbent to the sitting position. He passes the day "in a heap," as it were, without power to sit upright. Both upper limbs are very small. The left can be raised to the level of the shoulder-joint; the right cannot. The elbows can be flexed. The grasp is very feeble. The patellar tendon reflex is absent on both sides. He has no power of standing. As he lies on a bed there is just a faint power of moving his lower extremities. Both of these (like his arms) appear to be very small in comparison with the size of his body. There is very marked angular and lateral curvature in the lower dorsal region of his spine,

and this it appears has been increasing much during the last twelve months. It would seem to be due to weakness of the muscles of the back rather than to disease of the vertebræ.

Cutaneous sensibility is unimpaired in the arms, but is thought to be slightly diminished in the legs. In the right hip-joint there is marked stiffness, probably due to adhesions.

As regards the electrical condition in the upper limbs, all the muscles react to faradism in the following order of excitability: The forearms best; the arms next, the deltoids and pectorals least well; in the lower extremities no muscles of either lower limb (except those of the calf) react to faradism. In the right thigh there is very slight reaction to the interruption of voltaic currents from 40 cells. The same strength applied to the anterior tibial group produces no contraction, but being conveyed through, causes free contraction of the peronei and calf muscles.

In the back there would seem to be paralysis of both serrati magni, as well as of the mass of the erector spinae. These last react slightly (at least the superficial ones) to a very strong induced current.

The patient was treated by electric currents, and left the hospital on April 12 *in statu quo*.

In contrast with this preservation of a slight amount of contractility after many years, I would refer to another example in which at the end of a year no reaction to either current was to be obtained.

CASE V.—Cyril W., æt. 10, a fair-complexioned, very intelligent lad, was brought here on account of loss of power in his lower extremities of one year's duration. He could not stand. When seated, his legs dangled, the toes pointing downwards. In this position he could not move any part of the right foot or leg. The left leg he could swing forwards and backwards, but could not bring the foot up square with the leg. There was no loss of sensibility, and no affection of the bladder or rectum had existed at any time. The muscles of his legs were flabby. Tickling the soles of his feet was perfectly well perceived, but there was no retraction of the foot; the legs were objectively cold. Neither the strongest induced currents nor interrupted voltaic currents produced any contraction of the muscles of his lower extremities. There was no loss of cutaneous sensibility. It seemed that one day, about a year previously whilst practising gymnastics he struck his back (the lowest part of dorsal region is indicated), but so slightly that he took no serious notice of it and went on playing. A day or two afterwards he had a very bad headache and felt very sick. At 4 p.m. he went to bed, and slept for a time. In the night, getting up to pass water, he stumbled and found difficulty in walking. Next morning he could walk better, but his legs were still affected. During that day he could walk, but felt very ill and sick. He went to bed at his usual hour and then found himself very weak in the arms as well as legs. Next day he could not get up, and on being raised up in bed he felt great pain about the middle of the back. At this time his legs were quite powerless and his right arm became gradually paralysed from the shoulder to the elbow, but not, he says, in the forearm; this took upwards of a week to become complete. He could not lift his arm although he could use his hand very well. In about a month his right arm had quite recovered and before this the slight weakness of the left arm had entirely disappeared. On admission there was nothing whatever wrong with either arm. In this case I tried the effect of hypodermic injection of strychnia after a plan suggested by Mr. Barwell. The solution was of such a strength as that one minim contained gr. 1.50 of strychnia. Commencing with half this dose I increased the strength every alternate day until he was using gr. 1-12. These applications produced no physiological effect. The treatment was employed for a month. At the end of that time the condition of the legs remained as before, no contractions occurring to either form of electrical application. The

injections were then discontinued, and a daily administration of the constant current was employed. Both feet were placed in a bath with the negative rheophore and the positive rheophore with a strength of fifteen cells was applied for five minutes to the lower dorsal region of the spine. This application was continued almost daily for three months. At the end of that time the condition of the legs remained precisely as on admission.

CASE VI.—Another child, æt. 3, whom I lately saw, had been attacked when a year and a-half old with feverishness which lasted three days. At the end of that time it was found that the child, who had been very active in walking and climbing before her illness, could no longer stand. The right leg gradually recovered to a considerable extent. The left leg, notwithstanding electrical treatment which had been continued for a year and a-half, showed no improvement. At the end of that time I found that no muscle responded to either current.

## CERTAIN CONSIDERATION REGARDING CHOLERA AND FEVER. (a)

By SURGEON-GENERAL C. A. GORDON, M.D., C.B.,  
Honorary Physician to the Queen.

MR. PRESIDENT,—1. *Health Conditions in India*.—Here is an exact transcript of a weekly health Report (b) of India recently given in one of the public papers devoted more especially to information regarding Britain's greatest dependency, namely,—“*Bombay*: Health good. *Bengal*: Fever prevalent in Twenty-four Pergunnahs, Moorshedabad, and Rajshaye, Burdwan, Rungpore, and Purneah; cholera still in Cuttack. *North West Provinces* and *Oude*: Health good, except in Bareilly where fever and cholera (thirty deaths) have appeared. *Punjab*: Health fair. *Central Provinces*: Fever still prevalent. *British Burmah*: Rangoon and Akyah, health good; Bassein, a little small-pox; Promé, cholera decreasing. *Assam*: Health fair. *Mysore* and *Coorg*: Fever prevalent. *Central Indian States*: Morar, cholera disappearing; Rajpootana, Mewar, fever prevalent. *Others*: good.”

2. *Examination of Particulars*.—Let us examine the particulars just given, and these are the results which present themselves: The general health condition throughout India was unusually favourable; with the exception of places named it was good; at places far asunder as the Punjab and Assam, “fair”—that is, not absolutely good, and yet disease not prevailing to an extent to attract special attention. Elsewhere, however, one or other of the three forms of disease which most prevail throughout that country existed at different places, although, fortunately, with inconsiderable intensity as compared with their manifestations in the same localities on many previous occasions. Thus, fever was prevailing throughout the stations of Lower Bengal, also far away in one direction in Mysore and Coorg, and far away in another in Rajpootana; it lingered in the central provinces, while at Bareilly far away in a third direction, fever and cholera had both appeared, the advent of the latter malady signalled by the death of thirty victims. Elsewhere cholera alone is reported as present; in Cuttack as still prevailing; at Promé as decreasing; at Morar as disappearing; while at an extreme corner of the Empire, near one of the estuary mouths of the Irawaddy the record says—there is a little small-pox at Bassein.

3. *Deductions*.—That is, during the same week health conditions at the several parts of our Indian Empire differ absolutely from each other—a circumstance in accord with existing differences in physical condition and aspect of places far apart from each other; differences in climate and seasonal changes; differences in kind and condition of vegetation at the same time in those places; differences in the condi-

(a) Read at a meeting of the Epidemiological Society of London, 2nd February, 1881.

(b) Week ending 8th October, 1880.

tions of their several populations; and doubtless also to the operation of certain great ulterior influences as yet only cognizable in their effects, but not solvable by the theory alone that a specific organic poison introduced from somewhere else or suddenly vegetating on the spot has for a time exerted its evil and deadly power upon humanity, then itself becoming dormant, asleep, disappearing or passing onwards in its work of devastation—the manner of its disappearance or progress as unaccountable according to the same theory as were the circumstances of its original development.

Two months elapse. At the end of that time the health conditions are thus reported (a):—*Bombay*: Fever continues, but is abating in Guzerat. *Bengal*: Fever still very prevalent in many places, and deaths reported very numerous in Nuddeah and Jessore. Cholera in Cuttack, Pooree, and Maldah, and some cases reported from Budruck and Deoghur. Small-pox in Pooree, Chumparun, and at Jhalidah in Manbhoom. *North Western Provinces and Oudh*: General health good, with the exception of slight fever in Bareilly and Agra, and some cholera in Fyzabad. *Central Provinces*: Good. *British Burmah*: Cholera in parts of Pegu, but few fatal cases; a little small-pox, otherwise public health good. *Assam*: General health fair. Fever about Gowhatti. *Mysore and Coorg*: Health good.

We compare the general results of these two health reports thus:—At Bombay, where health was good at the date first referred to, fever has in the interim occurred, and continued to prevail. In Bengal both cholera and fever still prevailed in the localities formerly named, with two exceptions, namely, Nuddeah and Jopore. Cholera had ceased in Cuttack, but appeared in Maldah, Budruck, and Deoghur. Small-pox occurred in several places previously free from the epidemic, particularly Pooree, Chumparun, and Manbhoom. In the North West Provinces and Oude health continued good as before. At Bareilly, where fever and cholera previously prevailed, only slight fever was reported; cholera had left that town, but appeared at Fyzabad. In the Central Provinces, where fever formerly prevailed, the population had become healthy. In Burmah the state of health was unaltered; but in Mysore and Coorg, where fever had prevailed, the state of health had become good. Thus, in what may be termed the ebb and flow of these three diseases indicated by the reports before us, we find ourselves face to face with some of the great problems of epidemiology.

4. *Method of Inquiry*.—If, then, we endeavour to follow the natural history of these scourges of mankind, either on the occasions now referred to, or on the others, when, with varying degrees of intensity, they have swept over continents, it seems to me that such endeavour is more likely to obtain that measure of success incidental to the pursuit of subjects from their very nature, abstract and abstruse, if we take a comprehensive view of the various conditions under which they severally or together occur, than if we confine attention to one set of those conditions to the relative omission of others perhaps less tangible. If organic pollution alone of air, earth, or water be the cause of cholera, how are the sudden appearance, culmination, decay, disappearance, absence for long periods of these diseases to be accounted for, conditions of air, earth, and water meantime remaining unchanged? How similarly with regard to fever, or a particular kind of fever? How far the circumstance that fever and cholera on one occasion prevail independently of each other; on another contemporaneously; on a third alternating with each other; individual cases of fever passing into cholera; others at their onset presenting the ordinary symptoms of cholera, developing into fever, and yet a third set, at their commencement manifesting symptoms characteristic in equal proportions of both those forms of disease? How with regard to an acknowledged infectious and contagious disease, namely, small-pox, on the first occasion named, limited to a spot of considerable size, remotely situated in the Eastern

division of our Indian Empire; on the second disappearing there, but occurring at places completely apart from each other, as are Pegu, Pooree, and Chumparun, to the exclusion of the vast intervening territory between those three localities. By what explanation do we account for its being so limited in both these instances to the localities named, whereas on other occasions it spreads onwards directly from place to place, within certain limits, devastating populations in its course? Are these several phenomena to be accounted for simply by the theories of organic pollution and contagion? For my own part, I say—No: they are not. And from this point of view I proceed with my further remarks.

5. *General Considerations*.—The teachings of past experience point to the circumstance that the law or laws in accordance with which small-pox has its periods of prevalence and of dormancy are not much dissimilar, if at all, from those by which cholera is regulated. We have been informed that particular forms of disease comprised in what may be termed the small-pox group, have their corresponding rise and fall. It is not assumed that actual affinity exists between that disease and cholera. On the contrary, there is this great difference between them—that by means of vaccination (a) individual susceptibility to small-pox becomes limited; that to cholera is decreased by any similar or allied process. But as regards cholera, so with small-pox, the bulk of evidence is to the effect that so long as the general epidemic of either disease is active, and what, for want of a more definite name, is indicated as *diffusive energy* remains in full operation, isolation of individual cases does not retard, far less prevent the expansion of morbid influence over the population of what French authors appropriately describe as the *epidemised* locality. Neither has it in bygone times been found practicable even by means of inoculation to extend small-pox during the intervals between periods of epidemicity. (b)

More intimate is the relationship which phenomena of cases and manner of prevalence of both cholera and fever as observed more especially in India, justify the belief that there exists between these two diseases. On this subject one of the very recent writers (c) on Indian diseases expresses himself in this way:—"Owing to the marked association of epidemics of cholera and fever in Northern India, and to the frequent similarity, especially on the North-West frontier, of bad cases of malarious fever to cholera seizures, some observers have been led to ascribe the two diseases to an identical cause." He adds—"The *identity* of the miasms of cholera and fever is not pleaded, but only their similarity, which is chiefly shown in the external conditions that favour them both." Northern India (d) affords many examples of the impossibility of predicting from the physical conditions of a locality the degree to which fever will flourish there. (e) Elsewhere throughout India a similar observation is ap-

(a) Is it the case, as stated by Copland, that, as small-pox has decreased since the introduction of vaccination, scarlatina, measles, pulmonary and cerebral inflammations have increased?—"Art: Epidemics—Dictionary."

(b) As a footnote I mention that in India the deity of cholera is Maree, or as the name is respectfully alluded to Maree-Ama; her hand-maid is Seetala, goddess of small-pox. In China the deity of small-pox appears to be Niang-Niang; she also must be mentioned respectfully. Thus, when in 1875 the late Emperor died of it, the *Pekin Gazette*, announced the event as "the enjoyment of the heavenly flowers." The Chinese theory of small-pox and measles is that they depend upon a poison inherited from the parents, which resides in the system till excited by external causes, like fire concealed in the flint.—"Customs Reports, January—March," 1875, p. 35.

(c) Macnamara, p. 120.

(d) Dr. Livingstone relates that in some parts of Central Africa he found some dry, sandy, and clean tracts, more dangerous, as regards fever, to encamp in than others covered with reeds and rushes. Mr. Hyde Clarke mentioned an instance of a town in Africa built in a healthy situation, and healthy until cultivation began. Three years afterwards fever broke out and ran through it all.

(e) Macnamara, p. 121.

(a) For week ending 9th December, 1880. See Allan's *Overland Mail*, 29th December, 1880.

pliable with regard to cholera, and the circumstance is recognised that in localities noted for the occurrence of malarial fever, diarrhoea, dysentery, and affections of the abdominal organs generally prevail. Even in England cholera, when it has occurred, has been most severe in low-lying places, such as were formerly the favourite homes of ague, and such as have subsequently furnished numerous cases of what has been described as "paludal enteric fever," a mixed type of malarial intermittent and typhoid (a); in other words malarial fever attended by intestinal complication. In India the occurrence of bowel affections with and without other organic lesion, and with and without fever, has as distinct an apparent relation to season as is presented by the course of vegetation in the same locality, or, indeed, any other natural phenomenon. So, also, in respect to fever distinctly "ardent" in type attended by cerebral complication; so with that the complication of which is pulmonic. Fever, diarrhoea, and dysentery (b) in that great country prevail simultaneously or alternate with each other. In all affections of the spleen, the liver, as also of other glandular and glanduloid tissues, sooner or later, occur as complications. In many instances ostensible causes of illness are apparent, but in many others such causes as are usually assigned fail altogether to account for their occurrence.

*Types and Unity of Fevers and Cholera.*—Both cholera and fever take place under various circumstances and conditions—individual and general. They also present in particular instances various types or modifications in their own special characters. Thus, cholera is met with in one set of localities in India occurring in isolated cases throughout all seasons, those isolated cases in certain seasons being the precursors of a general outbreak, in others not so; at times apparently induced by unwholesome articles of food or drink, at others following the administration of therapeutic evacuants. In a second set of localities cholera occurs in the shape of regular outbreaks at certain intervals of time during the intervening periods, all general conditions remaining precisely as they are during those outbreaks, and even sporadic cases so extremely rare as to be considered almost absent. When outbreaks of cholera do occur, they present certain modifications in their phenomena, these modifications observable when the epidemic of one year is compared with those of preceding years, the characters of individual cases with those of others; and even in certain instances where direct importation of the disease has been traced, assuming new, and it may be exaggerated, characters, in its new locality. Then again the disease presents various characters in individual cases—congestive or algide in one, asphyxiated or spasmodic in others; rapidly destroying life in one set more slowly than in another; the attack sudden and without premonitory warning in one; in another preceded by malaise or diarrhoea, or both; sometimes for a few hours, at others for some days. But neither in designating these several modifications, or others here unenumerated, in which cholera occurs, do we find a term applied in a specific sense, either as implying a particular manner of causation, a particular series of pathological changes—although such do occur—or a particular method of treatment to be followed. In all these fevers cholera is simply recognised under that general term, causation being looked to in reference to public measures of mitigation, and with a view, whether to be realised or not, of future prevention of a similar outbreak.

With regard to fever (c), so various are the characters

(a) Russell, p. 28.

(b) Sir Joseph Fayrer, in his Lettsoman Lectures, 1881, mentions that in India dysentery is often accompanied by malarial fever; that among the complications of the former is the typhoid form; that a close analogy exists between dysentery, diphtheria, and typhoid fever; that the disorganisation, although principally in the large bowel, has a tendency to pass the ileo-cæcic valve.—*British Medical Journal*, 29th January, 1881, p. 149.

(c) Dr. Cheevers records the occurrence in India of Pali plague and relapsing fever in 1815-19; of cholera in 1817. He states in reference to the severe epidemic of fever which prevailed in

and modifications, according to geographical position, climatic conditions, seasons, &c., acting upon individual diatheses, temperaments, habits, and other personal circumstances, that while, as already related, ancient Hindoo physicians reckoned thirteen different kinds, this category has in more recent years, on the one hand, been so expanded as to embrace some three hundred different species; on the other it has been so compressed as that only one fever is acknowledged to affect humanity, this one fever presenting so many modifications according to circumstances and conditions as related, yet itself preserving its unity in this multitude-fever, with this modification here, that other there, and so on.

Partly as a result of improved sanitation, partly also to a circumstance which has more than neutralised all sanitary measures that have been adopted in India since 1864, attacks of fever among our troops in that country are in the mass less violent, less acute, less ardent than in days before the great Sepoy Mutiny. On the one hand measures for preserving health, begun by army medical officers, while sanitary science was yet recognised only as "Medical Police," have been developed upon the lines then laid down; space in barracks has been increased three-fold, intemperance diminished, inducements created for men to remain in or near the barracks, instead of wandering. But against all these, and outbalancing them, is the one measure of short service, with the constant stream into India of young immature lads incidental to it. (a)

(To be continued.)

#### ON THE TRANSMISSIBILITY OF HYDROPHOBIA FROM THE HUMAN SUBJECT TO THE RABBIT. (b)

By THOMAS M. DOLAN, F.R.C.S.Ed.,

Medical Officer to the Halifax Union Infirmary. *Medical Press and Circular* Special Commissioner for Reports on Rabies and Hydrophobia.

In the *Lancet*, pp. 109, 184, 1880, I wrote two letters on the prevention of hydrophobia, at the same time suggesting a crucial test, viz., the inoculation of the saliva of the hydrophobe into a rabbit, in order to determine whether the disease was true or false hydrophobia. The subject is of great practical importance from a diagnostic point of view. It can only be satisfactorily solved by practical experiments. As hydrophobia is, happily, a comparatively rare disease opportunities for experimentation are but seldom afforded. The following additional facts throw a little more light on the question:

At the meeting of the Academy of Medicine, Paris, January 13th, 1881, M. Maurice Raynaud in his own name and in that of M. Lannelongue read a paper entitled, "A Note on the Transmission of Rabies from Man to Rabbits." He commenced by recalling the experiments of M. Galtier, who had established this fact and studied the period of incubation in the rabbit, which was generally found to be about seventeen days. In conjunction with M. Lannelongue he had repeated the

the jails of Agra, Umballah, Futtighur, Allyghur, Jeypore, Malwa, &c., in 1864, that it was variously described as true typhus, contagious fever, typhoid fever, and relapsing fever, in the same year of the Burdwan fever epidemic.

(a) Article in *Encycl. Brittan*. By Professor Traill, Edinburgh. Surgeon-Major Don in his paper read before this Society (pp. 285 and 286 of Proceedings, 1880) observes with regard to Bermuda that "the robust, big-chested and muscular man, often a hard drinker, did get fever, but not enteric. The man of altogether reverse physical type and development, often temperate or even teetotal, was the victim of enteric in an especial degree." Also "that the age at which there is the greatest proclivity to the development of struma, tubercle, and such-like diseases of low nutrition is that in which there is the greatest liability to enteric fever."

(b) *L'Union Medicale*, 20th January, 1881. Abstract of a discussion at the Academy of Medicine, Paris, 18th January, 1881.

experiments. A child, *æt.* 5½ years, was admitted on the 8th December, 1880, to the Hospital St. Eugénie with symptoms of rabies. It had been bitten on the preceding 10th November; classic symptoms of rabies developed. The child died on the 11th December.

Three series of experiments were made on forty rabbits:—

1st. Inoculation with fluids from the living child.

2nd. Inoculation with various fluids or tissue, taken from body twenty-four hours after death.

3rd. Inoculation from rabbit to rabbit.

The facts of the first series confirm the observations of previous authors: inoculability of the saliva, non-inoculability of the blood.

In the second series two rabbits inoculated with bronchial mucus from dead body succumbed, one in thirty-four, the other in forty-eight, hours. Six rabbits were inoculated with fragments of salivary gland; one died. Two rabbits were inoculated with produce of lymphatic ganglia; one lived two and a-half hours, the other recovered. The two roots of the trigemina were inserted under the skin of a rabbit, which died at the end of three days. A fragment of bulbs was inserted into another rabbit; death took place on the fourth day.

In the third series there was not a single failure. Using saliva from dead rabbits of preceding experiments, five died in a space of time varying from twenty to thirty hours. The blood of rabbit killed by inoculation of bulb produced death in thirty-two hours and forty-three hours. M. Raynaud concludes that the rabbits died of rabies.

The discussion on this paper was taken up by M. Colin (Alfort), who first objected to giving the credit of the suggestion to M. Galtier as it was known long before his time; and secondly, he urged that the rabbits died of septicæmia and not of rabies. In the herbivora rabies went through a longer incubation than that described in M. Raynaud's paper, and rabbits were particularly sensitive to septic influences.

M. Dujardin-Beaumetz shared the opinion of M. Colin. To produce rabies in rabbits the saliva should be fresh.

In reply, M. Raynaud admitted the gravity of the objection raised by M. Colin; but he did not see how the deaths could be attributed to any other cause but rabies.

*Experiments of Pasteur.*—On the invitation of M. Lannelongue M. Pasteur went to the Hospital Saint Eugénie to conduct some experiments on the above-named subject. On his arrival the child had been dead about four hours and a-half. Taking some salivary mucus from the buccal cavity he inoculated with it two rabbits; death resulted in thirty-six hours. With the saliva of these two rabbits he inoculated two fresh rabbits; death again resulted.

*First fact: The transmission, by means of saliva, of the disease from which the two first rabbits died.*

On opening the two first rabbits the ganglia of groin and axilla were found much swollen; the same symptoms were noticed in the lymphatic ganglia on the right and left of the trachea. These ganglia were also the seat of sanguineous engorgement; all the vessels were gorged. The mucous membrane of the trachea was equally in a state of sanguineous extravasation.

*Second fact: Examined by the microscope the blood of these rabbits contained a special microscopic organism, having the form of a figure 8, about a millionth of a millimetre in size, and surrounded by a kind of gelatiniform aureola. Placed in suitable medium for culture the organism fertilised, still preserving its figure of 8 character. It multiplied in the usual way.*

This organism was, according to Pasteur, the cause of the disease and death of the rabbits in the experiments of MM. Raynaud and Lannelongue, as well as in those of M. Pasteur and his collaborateurs MM. Chambertard and Jouve.

What is the disease produced by inoculation in these rabbits? Is it rabies? M. Raynaud says yes. MM. Colin and Beaumetz say no. Pasteur declares he does

not know, the only fact being that the rabbits died as a result of inoculation of the saliva of a child who had died of rabies, and that there is a special mycelium at work which differs from the bacterium found in septicæmia. This discovery is another step onward in the direction pointed out by me in my Reports on Rabies and Hydrophobia (a) of 1877. I then said "Further research is necessary, and experiments with the virus, as dissecting or excising the bitten part and introducing it into some animal and watching the effects. Now that *bacteria* plays such a part in disease I shall expect some results in this direction and a further explanation of the remaining part of the phenomena." In the hands of such an inquirer as Pasteur the phenomena above noticed will, I have no doubt, receive their due scientific appraisal, and may lead to further results. At present we must receive with caution M. Raynaud's opinion that the rabbits died of rabies. They certainly had not a long period of incubation, nor were the symptoms characteristic. Some English experimenters will, I hope, take the matter up, and when opportunity offers repeat these experiments.

M. Colin at a later discussion, January 18th, 1881, urged that the organism described by Pasteur is well known and had been previously delineated by himself, that it was found in diseased conditions. To this Pasteur replied that he had taken all precautions against error, and did not agree with M. Colin as to the existence of this special organism in cases cited by him.

I hope in a few weeks to submit to the readers of the *Medical Press and Circular* some observations and experiments with saliva taken from a woman who died under the care of Dr. Berry, at Wigan.

#### COLLES'S FRACTURE. (a)

By JOHN F. KNOTT, F.R.C.S.I.

(Concluded from page 91.)

BONNET (de Lyon), writing in 1845, gives the results of his experiments on the cadaver, with the object of producing fracture of the radius by forcible extension of the hand. He was nearly always successful in establishing a solution of continuity; but in only one of eight cases did deformity co-exist with the other signs of fracture. He never succeeded in procuring fracture of the end of the radius by flexion of the hand. He ruptured tendons and ligaments, and sometimes even fractured some of the carpal bones, but made no impression on the bones of the fore-arm.

In 1846, the views of Voillemier, which now held almost supreme sway, were ingeniously contested by Jarjavay. He asserted that Voillemier had been deceived by the appearances presented by united fractures, from the fact that the periosteum, which is very strong on the posterior surface of the carpal end of the radius, is seldom torn, but being detached for a short distance from the seat of fracture, leaves an interspace, which becomes filled up by spongy osseous tissue.

Malgaigne, in his splendid work on Fractures and Dislocations, examines the different theories which have been propounded, and gives special attention to three of them:—(1) The inflexion hypothesis of Nélaton; (2) the penetration theory of Voillemier; and (3) that of *anachement*, to which attention had been already directed by Voillemier and others, but to which Malgaigne accords an importance which it had not hitherto enjoyed.

Verneuil, in 1851, published the result of a series of experiments on the dead body, with the view of determining the conditions which lead to deviation of the hand, and especially abduction. He had been led to believe that the latter deformity could not exist without previous laceration of the triangular fibro-cartilage or wrenching off of the styloid process of the ulna.

(a) "Rabies and Hydrophobia," 2nd Edition, p. 153. London: Baillière, Tindall, & Cox.

(a) Read before the Surgical Society of Ireland,

Foucher, in 1852, presented a number of specimens of this lesion to the *Société Anatomique*, and believes the mechanism of the fracture to be usually that of *anachement*. Impaction may take place; but he does not look upon it as an essential feature, and the backward displacement of the carpal fragment is explained by the *mouvement de vascule* of Pouteau.

A new and rather paradoxical theory was propounded by M. Lopez in his inaugural thesis of 1860. According to this writer, the inter-osseous ligament plays the principal rôle in the mechanism of fracture of the lower end of the radius, the position of the solution of continuity being determined by the absence of that supporting membrane near the carpal end of the bone.

M. Lecomte, who undertook the refutation of the thesis of M. Lopez, adapted definitely the theory of *fracture par anachement*. He combats the idea of Nélaton that the radius gives way because it is caught between two opposing forces, and believes that the columns of support which Nélaton described, do not come to bear upon the surface of the ground at all. This he attempts to prove by the simple experiment of marking with ink on the surface the prominences formed by the pisiform bone and trapezium, and then placing the extended hand on a sheet of white paper, the mark of the pisiform is never reproduced on the paper. The agent in the *anachement* of the lower end of the radius is the anterior radio-carpal ligament: divide this ligament previously, and no degree of subsequent extension of the hand will affect the radius, nor is the fracture produced by forcible flexion, even when this ligament remains intact. Impaction may or may not exist; it is not by any means an essential feature, and he agrees with Jarjavay, that the preservation of the periosteum posteriorly is a source of subsequent deception, as it leaves a space for the formation of a new layer of osseous tissue between it and the surface of bone beneath, so as to give rise to the idea that penetration had taken place, where it had really never existed.

The testimony of all unprejudiced observers since this date leaves hardly any room for doubt that this fracture may exist either with or without impaction, and also that the differential diagnosis of the two conditions cannot always be made with certainty except in the rare cases where an opportunity is afforded of examining the specimen. The ablest, as well as the most uncompromising, of all the opponents of Voillemier's theory, was our distinguished fellow-country man, Robert William Smith. In his valuable work on "Fractures and Dislocations," he upholds with the greatest firmness his belief that the doctrine of fracture with penetration is untenable, and that the distinguished French surgeon has allowed himself to be too easily imposed upon by the fallacious phenomena sometimes presented by consolidated fractures of the lower end of the radius. He believes the occurrence of any appreciable impaction while the ulna remains unbroken, and the ligaments connecting the extremities of the bones are intact, to be a physical impossibility. The position of Voillemier's diagnostic line of compact tissue he explains by sub-periosteal osseous deposition, while he points out another fact of great significance, which seems to have escaped the notice of all previous observers, that the distance between the lamina of compact bone, and the posterior surface of the lower fragment, does not correspond to the extent of the backward displacement of that fragment, as it should if the views of the French surgeon were correct. He bases his views on the evidence afforded by examination of more than twenty specimens of "Colles"—one of which was recent—and also points out that the length of the supposed penetrating line of compact tissue does not correspond to the amount of posterior shortening of the radius. The thickening of this layer, which had been observed by Voillemier himself to exist in old fractures, and which he confessed his inability to explain, Smith readily accounts for by the deposition of new osseous matter. The deformity so characteristic of the fracture is referred by the Dublin surgeon to muscular action, while crepitus and mobility, usually so

obscure, can, he believes, always be obtained if rotation be judiciously employed, after having previously used an amount of extending force sufficient to remove the deformity. The line of fracture, he believes to be, in the vast majority of cases, transverse, and even when oblique, he does not admit the possibility of over-riding of the fragments.

Of the more recent contributions to the literature of Colles's fracture, one of the most interesting is that of Chiene, of Edinburgh. To a description of the dissection of a recent specimen, he adds some ingenious remarks on the nature of the mechanism by which the lesion is produced. In falling on the hand, the force which is received chiefly by the ball of the thumb, is transmitted through the carpus to the lower end of the radius. The nature of the lesion then produced will vary with the angle of inclination which the fore-arm makes with the ground. If this be less than 60°, the line of force travels upwards *anterior* to the axis of the fore-arm, and the whole shock is borne by the lower end of the radius, which gives way near its carpal end. But if at the moment of impact the angle of incidence be greater than 60°, then the line of force, instead of passing in front of, passes directly up the arm, and "the usual result is either a severe sprain of the wrist, or dislocation of both bones of the fore-arm backwards at the elbow-joint."

This writer admits the existence of a slight degree of penetration in many cases, but not sufficient to justify the application of the term impaction, by which he would understand the condition in which the distortion cannot be removed by justifiable force. Such slight penetration did exist in the specimen which formed the subject of the communication, and the thin plate of bone much deeper behind than in front, which had been separated from the end of the radius, was found to be divided by two vertical cracks into three fragments. The tip of the ulnar styloid process was also broken off, but the triangular fibro-cartilage preserved its attachments, and the inferior fragment was found, in addition to the backward displacement, and partial revolution on its transverse axis, to have undergone the rotatory movement, described by Goyraud, in the arc of a circle, whose centre is placed at the ulnar attachment of the triangular fibro-cartilage.

Dr. Gordon, of Belfast, found as the result of a careful examination of twenty-seven old specimens of Colles's fracture, that the distance of the break, varied posteriorly, from three-eighths of an inch to an inch and three-quarters from the carpal margin, and from two-eighths of an inch to two inches in front. In nineteen cases the fracture was oblique from before backwards, in eight directly transverse. To the question of the existence of impaction he gives no attention, but he argues very strongly in favour of the cross-breaking mechanism of the fracture, produced by the strain of hyper-extension. The idea that the solution of continuity is produced by violence transmitted through the carpus, directly to the end of the radius, he summarily rejects, as he believes that if this were the true explanation, the fracture would be found to radiate from the point struck.

The only indisputable evidence which can be collected on the subject of the much-versed question of impaction, is that derived from the examination of recent specimens. Of the records of such, Dr. Wight, of New York, collected examples. One is by Professor Hamilton, of New York, in which the autopsy showed the detachment of a considerable fragment from the posterior lip of the articular surface; the direction being upwards and backwards. Two have been reported by Mr. Erichsen; in the first the lower fragment was split into three portions, between which the upper fragment was firmly impacted to the depth of half-an-inch. The largest fragment of the three comprised the whole of the articular surface, which was uninjured. In the other case the injury had been caused by a fall from a height of twenty-five feet, and the lower fragment, which had been separated by a transverse line about half-an-inch above the articular end of the bone, was found to be completely comminuted. Two other cases were examined by

Professor Gross, in one the carpal fragment was found to be separated into two pieces by a fissure leading into the joint, in the other, a much more extensive comminution had taken place. In an example recorded by Professor E. M. Moore, the fracture was found to be transverse, and although crepitus could not be detected during life, there was not the slightest trace of impaction. The tip of the ulnar styloid process had been wrenched off with the internal lateral ligament. In the second fore-arm of the same body, a fracture of the carpal end of the radius was found to exist, which ran in an oblique direction from above and behind downwards and forwards, and the apex of the styloid process of the ulna was torn off.

Dr. Hector Cameron, of Glasgow, has reported the examination of two recent specimens. In the first the line of fracture was transverse from side to side, and oblique from before backwards, the lower fragment being one inch in length behind, and a quarter of an inch in front. The carpal fragment was slightly comminuted, and the lower surface of the upper fragment, which was extremely rough and denticulated, sent a toothed process in the spongy tissue of the lower piece, and so firmly nailed it in its new position, that it required great force to separate them. In Dr. Cameron's second case the fracture was transverse in both directions, and situated about an inch above the carpal extremity. In front the fracture was hardly complete, the periosteum remained unbroken; but there was a well-marked backward hinging of the carpal fragment, and an examination of the posterior aspect showed a complete solution of continuity, whilst the compact outer layer of the upper fragment was driven firmly into the spongy tissue of the lower, splitting the latter into three pieces, which it, at the same time, held securely together, the impaction being complete and irreducible.

Dr. Pitcher, of New York, has lately advanced an entirely new theory of the nature and mechanism of fractures of the inferior extremity of the radius. This part of the bone is formed of "a cone of cancellous tissue, which is grasped above by a cylinder of strong, thick, compact walls. All force transmitted to the lower extremity, other than that of very great intensity is here finally decomposed and repelled." If, on the other, the violence be very great, the carpus acts as "a blunt wedge; driven against the concave articular surface of the radius with sufficient violence, it will split it longitudinally. There is no possibility of a cross-breaking strain being exerted, and, if in any case, transverse lines of fracture are found, they must have been occasioned by some other mechanism." This theory is borne out by the evidence collected from the examination of eleven specimens of recent fracture, collected in the museum of the New York Hospital, and one in the possession of Professor Hamilton. Ten of the twelve present both vertical and transverse lines of fracture; in some the vertical fissures extend into the shaft above the line of transverse separation. But the most remarkable corroboration of this writer's view was afforded by a specimen presented in 1858 by Professor Bigelow, to the Boston Society for Medical Improvement, in which the carpal articular surface presented a star-shaped crack, from which corresponding fissures passed up into the shaft for more than an inch, but without transverse fracture. This was the second example of the kind that had been met with by Dr. Bigelow.

Among English surgeons of late years, who have taken up the much vexed question of the mechanism of Colles's fracture, the most decided opinion has been expressed by the late Mr. Callender, who surpasses even Voillemier himself in the vehemence with which he advocates the theory of impaction. Basing his belief on the evidence afforded by the dissection of three cases, in each of which the fracture had been caused by very extreme violence, he considers that "there can be no question but that impaction is the cause of the displacement."

An examination of all the facts and theories which we have collected on the subject will, we think, leave no doubt on the mind of any unprejudiced inquirer that a great

variety exists both in the forms, and probably, also, in the mechanism of production of the fractures of the lower end of the radius. As Professor Bennett has well observed, "we have ample proof that the simple transverse fracture, without impaction, the impacted, and the fracture *par écrasement*, with a shattered lower fragment, are all possibilities," and there can be little doubt that modifications in the mechanism of production exist to a corresponding degree. I have not myself come forward as the advocate of any one hypothesis, for I do not believe that anyone can be successfully manipulated so as to adapt it to all cases; nor do I attempt to broach any new theory, for I think there is no room left for further innovation, and those with which we are already acquainted, if judiciously applied, will be found amply sufficient. I should, therefore, perhaps, in conclusion, apologise for trespassing so far on the time and patience of the members of this Society in the discussion of a subject on which I do not pretend to teach anything new, and was only encouraged to do so by the belief that any contribution to the literature of this subject would be listened to with partiality by the members of the Surgical Society of Ireland, in the long roll of whose names that of Abraham Colles shall always hold one of the proudest and most conspicuous places.

## Clinical Records.

### LARIBOISIÈRE HOSPITAL, PARIS.

*Suppuration of a Goitre during Convalescence from Typhoid Fever—Cure of the Goitre.*

Under the care of M. HUCHARD.

(Reported by M. WEILL, Interne.)

G—, a journeyman, *æt.* 22, entered the Lariboisière Hospital Aug. 11, under the care of M. Huchard (for M. Jaccoud). He had lived in Paris four months; when he came he had never had any disease in his own country, but he had a goitre of medium size; the diameter of the neck about the middle 54 centimetres. The skin over the tumour was normal. The tumour was of marked consistence, and the affection he said was common in his country. (Chambur, Italy).

For eight days he had felt weak and indisposed. He had lost his appetite and bled from the nose. Being unable to work he had gone to bed. After two days, diarrhoea came on, headache increased, and this condition continued up to his entry into hospital.

At a visit on Aug. 11, the patient presented a very dejected appearance. Great weakness and somewhat profuse diarrhoea. A few rose spots. Temp., 39°3 deg. C.

From the 11th to 28th Aug. typhoid fever ran its usual course with nothing remarkable to notice, and under simple treatment.

Aug. 23.—Temperature normal and patient feels very well.

Aug. 29.—He complains of pain in the neck, and there is slight redness on the surface of the goitre.

The following days the pain persisted, the redness spread, and the goitre increased in size: at the same time the temperature rose from 37 deg. C. to 38°6 deg. C.

Sept. 1.—The consistence of the tumour had much diminished, but fluctuation was not perceptible. The patient complained of obstruction to the movements of respiration and deglutition.

Sept. 6.—M. Humbert was called to see the patient. He found considerable increase of the goitre, which indeed was doubled in size. The skin was very red, and around the tumour was slight œdema; lastly, through the whole of the tumour was well marked fluctuation.

M. Huchard, seeing that the whole tumour participated in the inflammation, gave it as his opinion that the thyroiditis would result in the cure of the goitre, an opinion, as we shall see, absolutely confirmed.

Sept. 8.—An incision was made at the most prominent point, a little on the left side. A large quantity of pus escaped. A drainage tube was inserted to the bottom of the wound and Lister's dressing applied. At the end of ten

days the temperature fell again to 37 deg. C. The phenomena of pressure had completely disappeared. Carbolic injections were made in the wound daily.

The tumour disappeared little by little, and the patient left for Vincennes completely cured, early in October.

The diameter of the neck is now little more than normal; two or three small nuclei may be felt on the sides of the larynx.

This case seems to present two interesting points :

1. The complication of this special inflammation in the convalescence from typhoid fever.
2. The cure of the goitre as the result of this inflammation.

## Translations.

### ON THE VALUE OF OPERATIONS WHICH INVOLVE INCISION OF THE MEMBRANA TYMPANI.

By Dr. J. POLLAK, of Vienna.

Translated by W. DOUGLAS HEMMING, F.R.C.S. Ed.,  
Bournemouth.

[The following paper translated from the *Allgemeine Wiener Medizinische Zeitung* will be read with interest by British otologists for the reasons given by the author in the opening outlines.—W. D. H.]

The otological section of the International Medical Congress to be held in London, in 1881, has chosen the above among others as a selected subject for discussion. Since I shall scarcely be in a position to be present at the Congress, I take this opportunity of recording my experience in relation to this point, for the last five years, at the Aural Clinic of the General Hospital, which may be interesting also to non-specialists.

Paracentesis of the drumhead is performed almost exclusively in diseases of the middle ear. 1. To remove exudation from the tympanum (serum, mucus, pus, blood). 2. To remedy abnormalities of curvature of the membrane (abnormal tension, relaxation, cicatricial contraction, adhesions). 3. To enable one, through the perforation, to perform tenotomy of the abnormally contracted intrinsic muscles of the ear (tensor tympani and stapedius); and lastly, 4. To furnish a direct passage for the sound waves to the stapes and the membrane tympani secundaria, in anchylosis of the incus or malleus, or of both together.

Of the technicalities of the operation it may be remarked that it is best performed through a wide short speculum, by means of a lance-shaped paracentesis needle not too small. In order to have both hands free, it is well to use a forehead-band reflector for illumination. The size of the incision and its nature must vary according to the object of the operation. Under no circumstances should it be less than 2 mm. long. After the performance of the operation any irritation of the wound, even by the injection of lukewarm water must be avoided, and the meatus should be closed to prevent congestion of the head.

I.—The exudation from the diseased tympanic mucous membrane may be (a) purely serous; sero-mucus; gelatinous-like nasal mucus; colloid or (b) muco-purulent; purulent; or sanguinolent.

In the forms of exudation included under (a) which correspond to a catarrhal affection of the tubal and tympanic mucous membrane, the drumhead as a rule appears drawn inwards, the short process of the malleus projects forwards, the handle of the malleus is drawn inwards and backwards, and as a result it appears foreshortened, and in not a few cases apparently covered by the much swollen posterior layer of the drumhead.

Inflammatory appearances are almost always wanting in the membrane. When, however, the membrane has not been altered in its texture by previous pathological changes, we see through it the golden yellow or bottle-green (Politzer) exudation, and since the exudation better refracts the light, and the tympanum is contracted from without inwards; there are often also visible the long process of the incus, the promontory and the depression for the fenestra rotunda. If the exudation does not completely fill the drum, we remark on the membrane a hair-like line generally black, the line of demarcation

of the exudation; which, when the latter is serous, changes its position in movements of the head like a water level.

The disturbance of hearing in this form of disease, middle ear catarrh, is dependent, on the one hand, on the abnormal tension of the membrane and the ossicles and their consequent imperfect power of vibration; on the other hand, on the pressure which the exudation exerts on the plate of the stapes and the fenestra rotunda, and on the alteration of the vibrating medium in the tympanum.

Therapeutically, vigorous inflation is indicated either by Politzer's method, or failing that, by catheterism of the Eustachian tube. By this operation, not only is the abnormal tension of the operation overcome, but in many cases by improving the state of nutrition of the parts, an absorption of the exudation is brought about. The latter is especially the case in serous or sero-mucous exudation, in which, as Politzer shows, by putting the head downwards, and towards the side opposite to that of the affected ear, by which the tympanal end of the tube is directed downwards, an outflow of some at least of the exudation may be produced by the air douche. This, however, becomes impossible in the gelatinous, naso-mucus-like, lumpy exudation, for the absorption of which by the usual treatment by the air douche, weeks, months even are required, and in difficult cases it is not even effected at all. It is especially in the treatment of such forms that paracentesis of the membrane is indicated, although in cases of serous exudation also a marked diminution in the duration of the treatment is obtained by paracentesis.

The incision, not too small, is best made in the posterior inferior quadrant of the membrane, whether it be vertical or horizontal, as proposed by Binz, is a matter of indifference. From its easy practicability and freedom from danger (I have, by observing the above-mentioned precautions, out of about 500 cases only seen inflammation follow in one single case), this operation claims a permanent position in the therapeutics of exudative middle ear catarrh. The immediate result is striking. It is sufficient that the causal indication must be satisfactory, and in order to prevent relapse, for some time after the operation the tube must be kept pervious.

II.—In acute otitis media, among other inflammatory appearances in which the membrane participates, there occurs an effusion of a mucous or purulent exudation in the tympanum. By this the membrane, especially at its posterior superior quadrant, is pressed outwards and shows the characteristic appearance of myringitis.

In the course of acute middle ear inflammation, besides the disturbance of hearing, the severe pain, the gradually disturbed condition (temperature up to 41 deg. C.), and in some rare cases the symptoms of meningeal irritation render therapeutic interference necessary. Opening of the tympanum by incision of the membrane is by most aural surgeons, equally with oncotomy, valued and used.

After the experience which I have had during the last five years, in the abundant material of the Vienna Aural Clinic, I must agree with the view which Politzer has decidedly pronounced in regard to the frequent performance of paracentesis of the membrane in painful inflammation of the middle ear with redness and swelling, and he only recommends it "when examination of a membrane shows that rupture may be expected, that is, when there is a greenish yellow tint of part of the tightly stretched membrane, or further, in livid red swelling of the membrane, when the pain is very severe and can be removed by no other therapeutic means." According to my experience, which is in agreement with Politzer's, the process often goes on to complete *restitutio in integrum* without perforation of the membrane, whilst, after incision has been performed, a long continuing discharge is almost always set up. Especially is this the case in weakly, cachectic, scrofulous, and tuberculous individuals.

The incision should be made in the most bulging part of the membrane, in the posterior superior quadrant.

(To be continued.)

THERE were fifteen deaths from small-pox in London last week of children under five years of age; of these, thirteen were unvaccinated. Another awkward fact for the anti-vaccinators.

## The Mineral Waters of Europe.

### THE "MEDICAL PRESS" ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, &c.

WITH

### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P.Lond.,  
Lecturer on Materia Medica and Therapeutics at the London  
Hospital, Physician to the Hospital for Diseases of the  
Throat, &c.

(Continued from page 82).

#### GLAUBER'S SALT WATERS.

WE now come to a group of waters distinguished by containing sulphate of soda, but none of the corresponding salt of magnesia. We have seen that there are numerous cases in which either or both of these saline purgatives are useful. There are others in which the soda salt is more appropriate. It is very often stated that Glauber's salt is more nauseous and also more irritating than Epsom salts, and some attribute the popularity of the latter to these qualities. Not only are both these assertions disputable, we consider that the reverse of them would be nearer the truth. It is possible some persons may consider one salt less nauseous than the other. *De gustibus non disputandum.* But with regard to their relative efficacy it is more important to have a correct idea. We have no doubt whatever that the magnesian sulphate is more irritating to the intestinal mucous membrane than the soda salts. When taken alone, the former may be considered half as strong again as the latter, and many persons will find it act twice as powerfully, but in mineral waters it is not alone. The carbonate of soda, chloride of sodium, and even the carbonic acid modify the action. The effect of the waters is therefore a complex one. For single purgative doses this may not signify, but for prolonged courses it is of great importance. Glauber's salt acts in the same manner as Epsom salts, but is less irritating. It can be given in large quantities. Accordingly, its single dose is larger, but for continuous use the ratio is not the same. It may be pushed until the artificial diarrhoea becomes distressing, but this is not so soon the case as when the mixed salts are employed. The so-called "critical diarrhoea" about which so much has been written, is the natural result of continuing too large doses of any of the purgative waters, although it may also be brought on by errors in diet, or by taking cold. In the leading mineral waters, however, considerable influence must be assigned to the modifying ingredients. Of these, carbonate of soda is perhaps most important. It is a most effective corrigent, and may perhaps claim to serve also as an adjuvant. It will be readily admitted that the corrective influence on the stomach may be serviceable, but we believe this influence extends along the intestines. Anyone who has much experience in the treatment of

irritative diarrhoea, by alkalies, will admit this. But, then, we ought not to forget the effect of this carbonate as a solvent of the albumen of the blood, and thus as a promotor of serous transudation. If this be increased, we can easily see that a minor degree of stimulus to the intestine should suffice to produce purgation. In the same way chloride of sodium may be shown to be a more important ingredient than is sometimes supposed. It stimulates gently the mucous membrane of the alimentary canal, and also the muscular fibres of the intestines; when absorbed it promotes tissue change, and apparently aids the cell formation. Its digestive action is well known. These two salts are therefore admirably suited to reinforce the sulphate, and the mineral waters thus constituted are remarkable for their efficacy as well as for their mildness. Further, on account of the carbonic acid which they also contain, they act more easily on the stomach and are more acceptable to the palate.

In these waters, then, we have saline aperients which are powerful promoters of tissue metamorphosis. They cause a sensible decrease in the body weight, chiefly by the loss of superfluous fat, for the muscles do not diminish in volume, and the appetite, digestion, and assimilation, improve under their judicious use. It is only when pushed to extremes, or in unsuitable cases, that injurious irritation is set up. The increased tissue change would thus appear to be counteracted by the removal of fat. At the same time we must admit there is also considerable increase in the elimination of nitrogenous material through the bowels. This is partially compensated for by decrease in the elimination of nitrogen by the kidneys, which Prof. Seegen has shown to be produced. Though, as will be seen, we do not accept the view he advances, that there is an absolute reduction of eliminative activity, but regard the lessened removal by the kidneys as more than counter-balanced by the bowels. In the use of such agents it is obvious that diet and regimen are of the utmost importance, and at the principal spas these are regulated with no slight rigidity. Some further details will be given under the individual waters.

*Carlsbad*, the only hot spring of the group, is the most important, on account of its remarkable position, its ancient repute, and the valuable researches which have been accumulated respecting the therapeutical effects of the waters. As early as 1522, Dr. Payer produced his *Tractatus de Thermis Caroli, IV.*, and about half a century later Dr. Sumner published the composition of the waters. Drs. Schackern and Springsfeld showed the remedial uses of the waters, and in 1772 appeared Dr. Becher's *Neu Abhandlung von Karlsbade*. The last-named author appreciated to a remarkable degree the qualities of the waters, and the cases for which they were adapted. Some of his observations might well be thought to have been recently written. Many eminent physicians have since discussed the subject in all its bearings, and Dr. Seegen still continues his important experiments.

Carlsbad is not adapted for use as an occasional purgative. The dose would be too large, and, indeed, some

authors distinctly deny its purgative action ; but the first few doses almost invariably produce increased alvine evacuations. Still the best and most lasting effects are obtained from moderate doses. At the springs it seems to be a common practice to gradually increase the dose, which varies from two to ten glasses of six to eight ounces each. The whole quantity is taken before breakfast, walking in the open air between the glasses, the drinking thus occupying an hour, or an hour and a-half. The dose, small at first, is increased until several fluid evacuations are produced, and this degree of purgation may be kept up, and the quantity again reduced according to circumstances. It is obvious that a course of such treatment prolonged for weeks is a very powerful therapeutical process, especially when reinforced by appropriate diet. This last point is much insisted on at Carlsbad, and those employing these or other saline waters will do well to adopt a dietary approaching in character that which is there enforced, and which we may as well briefly state :—

*Breakfast* (to be taken an hour after the last glass of water)—weak tea or coffee with milk and a little sugar, well baked rolls or stale bread, no butter ; eggs, bacon, fish, or meat only permitted to very weak patients.

*Dinner* (at one o'clock)—Soup free from grease or flavouring, but may be thickened with rice, vermicelli, or pearl barley ; meat (beef, mutton, or lamb), or poultry, with well-boiled fresh vegetables, a light pudding, or stewed fruit. A cup of coffee is allowed in the afternoon, and a light *Supper* at eight o'clock. Light claret is only allowed in small quantities when the physician thinks a stimulus to the stomach needful. Otherwise, alcohol is absolutely forbidden. Smoking in moderation is tolerated. The following articles are forbidden : butter and fats of all kind, cream, cheese, pastry, pork and other rich foods, goose, sausages, salmon, herrings, anchovies, mackerel, *entrées*, and all seasoned dishes, peppers, onions, garlic, spices, cucumber, all salads and uncooked fruit.

This somewhat primitive and rigid diet would, without any other measure, produce a great effect in many persons, and in several points may often be relaxed. The absolute prohibition of butter, for instance, would often be a hardship, and its exclusion is not justified by science. It is only *excess* of fat that is injurious to digestion ; some of it seems actually to accelerate the formation of peptones, and the amount which thus facilitates digestion may well take the form of butter. In the same way the exclusion of ripe fruits and vegetable acids—originally founded on an error—need not be insisted on unless for some special purpose. Again, there are cases in which the meals should not be limited to three daily, and there are others in which the waters and the exercise make too great a demand on the strength of the patient unless a cup of tea or milk-and-water be permitted to precede. But while making these concessions we must urge the importance of a simple diet, carefully regulated on the lines laid down at Carlsbad.

(To be continued.)

We would remind those of our readers who intend subscribing to the "Habershon and Cooper Forster Testimonial Fund" that the list will close on February 28.

## Special.

### ARMY, NAVY, AND INDIAN MEDICAL ITEMS.

IN the House of Commons on the 4th instant :—Mr. Trevelyan, replying to Dr. Farquharson, said the report of the Committee on the pay and position of naval medical officers would be presented to Parliament as soon as the correspondence on some minor points had terminated. The terms of the scheme, however, had been virtually settled, and it gave the proportions of improvement as regarded medical officers in the navy compared with the army. The scheme of retirement would come into force on the 1st of April next. Successful candidates would receive full pay as surgeons from the moment of entering the service.

THE *Indian Medical Gazette* observes, with reference to the late illness of the Viceroy, that it has directed the thoughts of the profession (in India) to the subject of fever, a subject which must always occupy the front rank in that country ; that more sickness and mortality are due directly and indirectly to this cause than to all other causes put together. Dr. Payne, in his report on the Medical Institutions of Calcutta for the year 1879, showed that the number of cases returned under the head of enteric and remittent fever varied remarkably in different hospitals, and in the same hospital in different years, and he has ascribed the variation to difference in the theoretical views held by the medical officers in charge. Nothing, observes our contemporary, could more clearly indicate the need of more precise notions in this matter.

IT appears that the mortality of the 2-11th Regt., now in Candahar, is deplorable. In a few months the regiment has lost two officers and ninety men ; and, out of the 700 who crossed the frontier so recently, there are now scarcely more than 250 men fit for parade. Dysentery and diarrhoea, the diseases of the country at this season, have worked all the mischief.

H.M. Indian Troopship, *Euphrates*, which recently arrived at Natal with troops from Bombay, had on board the following medical officers, namely, Surgeons-Major Cherry, Scott, Barker, and Cornish ; Surgeons Mapleton and Gramby. The *Crocodile*, also with an Indian contingent for the same destination, had on board Surgeons-Major Roe, K-ir, Waghorn ; Surgeons Ward and Langridge.

SURG. W. K. HATCH, M.B., has been appointed to act as Professor of Pathology in the Grant Medical College, Bombay.

Is the report true that "doctors" who served in the Zulu war are to be denied the medal for that war ? Surely not. It is stated that soldiers and officers of the "combatant" branches are to receive medals for that war, although they may have had no actual fighting whatever, and yet medical officers, who performed their duty under fire, are to be deprived of the decoration. No doubt all this is a mistake, and we await the assurance that it is so ; otherwise, it savours not only of gross unfairness, but of actual indignity to the medical service.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 9, 1881.

### ALL-NIGHT SITTINGS.

THE British House of Commons has recently been the scene of occurrences which are likely to render the year 1881 one of the most memorable in parliamentary annals. In connection with the events comprised within the record of the past week or two, there are few of the fresh experiences undergone by members more significant than the all-night sittings, which, at one time, threatened to become

indefinitely prolonged. A canvass of the whole House of Commons would probably discover scarcely a single dissident from the proposition that health, and physique were undergoing irremediable mischief by those protracted debates, and that even the strongest representative must be injured, more or less, by a continuance of them. Coming in the way they did, as something beyond and above ordinary experience, they, by right of their unusual nature, received an amount of notice and consideration that fail to be bestowed on similar but less abnormal incidents. The House of Commons is, by no means, the only situation in which men, young, old and middle-aged, undergo the dangers attendant on all-night sittings. Not now and then, not once or twice, or perhaps three times a year, but night after night, week after week, and year after year, there are an uncountable number of persons who absorb the legitimate working day, and pursue far into night and early morning, the studies or the labours of their lives. The habit once acquired, it would almost seem that no effort of the will is competent to shake it off; and the consequences to the victim find expression in the wards of consumption hospitals, the paralysed and epileptic, and, in their worst forms, within the walls of the madhouse. We have no wish to threaten honourable members with any such result of their persistence in all-night sittings; although there are not a few among them who, by reason of advanced age and failing powers, might well absent themselves from a scene they can be present at only under such untoward conditions for them. To them, even infrequent repetitions of the demand made by a single all-night sitting on frames weakened through years, and exhausted by age, is met at considerable expense of vigour and endurance. The gentle exercise and excitement of an unprotracted sitting, they can endure and enjoy. It is within their ordinary powers, and lays no undue pressure on bodily resistance. But at once, when these favourable limits are exceeded, the overstrain commences, and, as it proceeds, it is met by fast declining efforts, until at length a total succumbing of the system, rewards the devoted legislator for his patriotic attempt to maintain the pressure brought to bear on him. Unfortunately, too, it most often happens that the men on whom the nation places highest value, whom it can least well afford to lose the services of, are just those more aged individuals on whom protracted vigils first commence to tell. In the national interest, therefore, it is eminently to be desired that the scenes rendered familiar in the immediate past shall not be re-enacted; and that no further necessity for the continued presence in the House of the more venerable of its members, shall arise as a consequence of any political incident. There will be far more difficulty, however, in bringing about that the many outside of parliament who waste health and strength in all-nights sittings, shall cease to submit their lives to the deadening influence of such practice. Necessity and inclination separately, or together, serve in every case of this kind to render difficult the task of breaking a custom grown familiar by long usage. How many men there are—fathers of families, even; others young, ambitious, and scheming—who neglect the future in the present, and who, by reckless calls upon their physical powers now, are laying up for themselves sickness and death in the not far distant time! In cities and towns these are to be found in every rank, in every

place, and in every stage. Some there are in all the hope and eagerness of youth; others on whom the dull apathy of certain illness has settled down, and destroyed all zest in life; and others, yet again, in whom the progress of disease has so far advanced, as to destroy all joy in living, and make death itself seem better than existence. In all of these it were not too severe to say, that all night sitting over work or study, had sown the primary seeds of that grew to yield such lamentable fruits.

In his daily practice the physician is brought into direct contact with the victims of an ill-judged devotion to business calls or intellectual excesses. His duty then is plain; and whether it be a senator that he forewarns, a student, or a professional worker, he should equally enforce the unceasing necessity of rest for the brain, during the hours of night, and abstinence from toil when the overworked, mind by flagging efforts at concentration, denotes the mischief already wrought, and the penalty that will surely follow disobedience of Nature's calls for repose. In the case of statesmen, the conditions are equally urgent, and carry with them even more anxiety, because in their well-being the successful prosecution of national undertakings is involved. The weariness induced by close attention to Parliamentary labours is, perhaps, greater than we are always prepared to believe; at any rate, it is grave enough to yield abundant excuse for the adoption of any and every expedient, whereby the burden of his duties may be lessened to the legislator. Each extra hour, abstracted from the necessary rest, adds something to the irrecoverable loss sustained by the physical powers; and it should be the earnest wish of every patriotic member of the body politic, to smooth away each fresh occasion of disturbance to the right relations between rest and work. To the larger class who are sapping their energies by unwise abuse, we can only, perhaps, best appeal by suggesting the injury they are doing to coming generations, who, by unalterable law, are destined to inherit the imperfections, as they will undoubtedly share the excellencies, of their living ancestors.

#### THE NOTIFICATION OF INFECTIVE DISEASE IN DUBLIN.

As we reported in our issue of Jan. 26, the Council of the Irish Medical Association has held a special meeting for the consideration of Mr. Gray's Bill, to introduce into Ireland the compulsory notification of infective disease by the attending physician.

A series of resolutions were submitted to the meeting by Dr. Jacob, and after some emendation, were passed in the following form:—

1. That this Association, while re-affirming the resolutions of the Council adopted on the 27th July, 1880, as to the advantages of early notification of infectious disease, is of opinion that the proposal to compel the physician to make a formal written notification either to the sanitary authority or to the custodian of the patient, would, if carried into effect, be of doubtful advantage to the public, and be oppressive upon the medical practitioner.

2. That this Association does not admit the principle that a physician should be required to apply to public uses the information obtained by him in his capacity of a private practitioner, and the Association furthermore apprehends that, if it be declared that the visit of a physician to a patient who may possibly be suffering from an infectious disease shall

be, of necessity, followed by the putting in motion of the sanitary law with regard to the infected house, a great inducement will thereby be afforded to defer calling for the physician until the disease has acquired such intensity that it can no longer be concealed and must be treated under great disadvantages.

3. That the Association cannot assent to the sacrifice of professional principles and medical interests which the Bill now before Parliament involves until the custodian of the patient has been made fully responsible, under penalties, both to ascertain from a medical practitioner the nature of the disease, and to report the same to the sanitary authority; and until after an effort made to enforce such responsibility with vigilance and firmness, it has been found impracticable to do so.

4. That irrespective of the objectionable principles of the Bill already referred to, the proposals to pay to the physician one shilling for thirty days' notification of cases occurring in an infected house—to pay no fee whatever for such services in a public institution—to compel the physician to attend in court, without fee, to prove his certificate, if necessary, and to impose a penalty of £5 upon him for such omission to notify, are altogether unacceptable to the profession.

5. That, therefore, the Committee of this Association be instructed to take all necessary steps to cause the Bill to be modified in its passage through Parliament, or to oppose its passing, if necessary.

These resolutions put beyond any doubt the feeling of the Irish Medical Association, and, we believe, the profession at large, as to Mr. Gray's scheme. The profession acknowledges that it would be very desirable that the sanitary authority should be informed at the earliest possible moment of the occurrence of infective disease, but it declares that the custodian of the patient, and none else, should be held responsible to furnish that information.

It is not alone on the ground of professional principle or medical interest that the Irish Medical Association deprecates the imposition of such a duty upon the physician, but because the patient himself would suffer from the disposition to keep the doctor out lest the sanitarian might follow him into the house, and because the inducement to conceal infectious disease, which is admitted to exist, would for a similar reason be greatly increased.

The opinion of the medical profession in Dublin upon this subject has been clearly expressed by the plebiscite recently taken by the Irish Medical Association. A circular setting forth the facts was forwarded to 371 persons whose names appeared in the Dublin list of the Irish Medical Directory. From these a considerable number must be deducted of those who, usually resident in that city, are absent from home either in ships, in the army, or else where. Thus about 280 resident practitioners received the circular, of whom 201 sent replies as follows to the questions submitted to them.

1. Do you approve of the medical attendant being, directly or indirectly, the informant, *in writing*, of the sanitary authority? Yes, 60; no, 104.

2. If you approve, which proposition (*a* or *b*) do you prefer. For *a*, 31; for *b*, 29; against either, 49.

*a*. That the medical attendant shall, on diagnosis of an infective disease, fill up, sign, and hand to the custodian of the patient, or to the occupier of the house, a printed notice which the recipient shall be bound to bring or send forthwith to the City Hall.

*b*. That the medical attendant shall, himself, transmit such notice to the City Hall immediately after he has left the patient.

3. If you do not approve of *a* or *b*, do you approve of *c*?

*c*. That the custodian of the patient, or house occupier, shall be the person responsible to ascertain from a medical man the nature of the sickness, and report same to the sanitary authority, subject to penalties for omission to do so.

Allowing for the probability that many of those who omitted to give any reply to these queries would object to the imposition of such duty upon them, it may be taken that at least two-thirds of the medical profession in Dublin are hostile to Mr. Gray's proposals, and will afford no assistance to their being carried into effect.

We trust that the decision of the profession thus expressed will satisfy Mr. Gray that his Bill, in its present form, will fail in its object, and that he will not press its second reading in Parliament until it has been altogether changed in its features.

Approving most warmly of any effort to amend the sanitary law of the city, we should be sorry that all idea of obtaining an effective system of notification should be abandoned, and there is no reason why it should be so. There are other propositions quite as practical and much less dangerous than Mr. Gray's, which ought to be talked over before legislation is attempted.

#### THE INDIAN MEDICAL SERVICE.

THE Defence Committee of the above Service has published "A Comparison between the Army Medical Service and the Indian Medical Service," and has, moreover, sent the document containing that comparison to every medical school in the United Kingdom. It is confessed that certain disadvantages under which the Indian service was considered to labour have lately been removed. The following, however, are looked upon as sufficiently grave to be thus formally enumerated, and, being so, we propose to consider them in their order, namely:—

##### 1. "STATIONS AND CLIMATE AFTER JOINING.

"The greater part of the *British surgeon's* service will be passed either in his native country, or in temperate and healthy climes, such as the Mediterranean and Cape Stations; and, even in India, the Order of the 2nd January allots to him permanently all the pleasantest and most salubrious stations in or near the Hills, such as Puna, Bangalore, Meerut, Rawal Pindi, Umballa, Mhow, &c.

"The entire service of the *Indian surgeon* must be spent in India, and at the worst stations—in torrid and malarious districts, such as Meer Meer, Scinde, and Central India—the cholera haunts, or fever-stricken plains, of Lower Bengal, Gwalior, Assam, British Burmah, and the Malabar coast."

We suspect that the framers of the above comparison have insufficiently appreciated the position of the Army medical officer. Those of that service who pass more than an infinitesimal part of their service in their native country, or in other "healthy" climates, are few indeed, and most especially fortunate; the many oscillate between such *healthy* places as Hong Kong, West Indies, &c. cetera. As to stations in India, if an administrative medical officer of the army is stationed at Bangalore there is one of the Indian service at Secunderabad—in every respect quite as good a place, and in the estimation of some people much better. As to Lower Bengal, we had thought Calcutta—the city of palaces, and even Barrackpore, to be among the most envied of Indian stations.

Rangoon, also, is certainly a more desirable place to be stationed in than Mhow. In all fairness, therefore, we really cannot see that, as regards this item, the comparison is adverse to the Indian service, but rather the contrary.

2. "PAY AND ALLOWANCES.

"When in India, notwithstanding his other advantages while there, the British army surgeon draws in some instances more pay and allowances than the Indian surgeon who is permanently quartered in that disagreeable and unhealthy country."

We cannot enumerate any advantages enjoyed by the Army medical officer in India over the Indian. If in some few—very few—instances the former draws more pay than the latter, in the great majority it is quite the other way. Army medical officers serve temporarily in India, and while there are moved about from place to place, the Indian medical officer settles down in a place, and there remains for years, often in the enjoyment of large emoluments, with every comfort that a magnificent house and large establishment can confer.

3. "IF HIS HEALTH BREAK DOWN BEFORE HE IS QUALIFIED FOR A PENSION.

"The British surgeon is transferred to a home station or some climate suitable to his case. If, however, he is reported unfit for further military duty, he is placed on half-pay on the following scale:—

If he has served—	
Under 5 years	£108 2 0
More than 5 years	146 0 0
" " 10 years	182 10 0
" " 15 years	248 7 6

"No change of climate is provided for the Indian surgeon. He must either work out his service in the climate which deprived him of his health until he dies, or leave that service for good, on far less liberal allowances!

If he has served—	
Under 3 years	£45 12 0
" 6 years	73 0 0
Between 6 and 12 years	127 15 0
Between 12 and 20 years	173 7 6
Over 20 years	200 15 0

As a matter of fact, an army surgeon invalidated from India before the completion of his tour of service there obtains exactly six months' leave upon full pay. If at the end of that time he is unable to return, he is placed upon half-pay, and may remain so for an indefinite period, losing not only emoluments, but "time" for promotion. The Indian Government is most liberal in regard to sick leave. If an Indian medical officer breaks down in health in the early part of his service his position, no doubt, is disadvantageous. On the other hand, once he has become "seasoned" to India, his chances of health are far better than those of the army surgeon, who has to face all climates, remaining for no long period in any one.

4. "ADMINISTRATIVE APPOINTMENTS.

"The proportion of these to the total strength of the service is much greater in the British Service, being for

Surgeons-general	Per cent. 1.09
Deputy-surgeons-general	3.4

There certainly ought to be equal prospects of advancement in both branches of the medical service, and in this respect we cordially support the present representation.

5. "DECORATIONS.

"In the British Medical Service there are—

2 K.C.B.'s and 12 C.B.'s, which is nearly 1 in 50 of its entire strength.

"In the Indian Medical there is—

1 O.C.B. which is exactly 1 in 666! officers."

In this respect, also, we are of opinion that an improvement is desirable. We notice the circumstance, however, that the "Comparison" makes no mention of either the Order of the Star of India, nor of that of the Indian Empire; several Indian medical officers belong to these, but none of the Army Medical Service. As a matter of pure right, we consider that good work, in whatever branch of the public service performed, ought to be acknowledged. Hitherto, the medical departments generally have been at a very great disadvantage in this respect, but there are rumours afloat that some improvement in this respect is contemplated.

6. "PENSIONS ON RETIREMENT.

"Granted to the British army surgeon—		"Granted to the Indian surgeon, irrespective of rank:—	
Surgeon-major, 20 years' service..	£365 0 0	After 17 years' service	£220
Surgeon-major, 25 years' service...	410 12 6	" 21 " "	292
Surgeon-major, 30 years' service...	456 5 0	" 24 " "	365
Brigade-surg., 20 years' service...	501 17 6	" 27 " "	456
Brigade-surg., 30 years' service...	547 10 0	" 30 " "	550
Deputy-surgeon general ...	638 15 0	with additional pensions to those who complete 5 years' service in administrative appointments.	
Surgeon-general..	730 0 0	Deputy-surgeons-general ...	£250
		Surgeons-general ...	350

For all, in fact, except the few administrative officers, the pensions are considerably less, though the service is entirely tropical."

For the reasons already stated, we consider that, as regards locality, India is infinitely a better and far more pleasant sphere wherein to serve than the larger, more various and variable, from one end to the other of which the army surgeon is liable to be buffeted. As regards pension, the Indian surgeon-general draws £900, the army surgeon-general £730—a difference in favour of the former of £170!

THE METROPOLITAN WATER SUPPLY.

PROFESSOR FRANKLAND'S last monthly report on the Metropolitan water supply is not altogether of a satisfactory nature, so far as the public health is concerned. We learn from it that the average amount of organic impurities contained in a given volume is, on the whole, large, and that the water drawn from the Thames by the several companies was of inferior quality to that supplied during the previous month. The water also, drawn from the Lea by the New River Company and East London showed deterioration, and was slightly turbid through inefficient filtration. On the other hand the deep well water of the Kent and Colne Valley companies, and the Tottenham Local Board of Health was of its usual excellent quality. A significant fact of importance as affecting the purity of deep well water.

In contradiction to this statement of an authorised authority, we notice a manifesto put forth by the companies, signed by three well known chemists, which has been forwarded to the President of the Local Government Board, and which concludes as follows:—"That considered both chemically and physiologically, the water delivered by the companies during the month over which their examinations extended, was of excellent quality,

wholesome, and in every respect well fitted for the supply of the metropolis."

Who shall decide when eminent chemical authorities so totally disagree? It does, however, appear to ourselves that chemists, as a rule, do in all documents of the kind, manage to avoid the most vital and important issue in the question of what constitutes a perfectly safe and pure water, and what does not. Why, in the first place, we may ask, was this examination undertaken at a period of the year when water is freer from organic impurities than at any other? During winter, and with the thermometer close upon, or below the freezing point, all kinds of organic life sink to the bed of the river, and become buried in the mud at the bottom. A very different state of things is brought about in summer time when the temperature of the Thames water ranges from 50° to 70° Fab. But putting this aside, even the quantity of organic matter contained in Thames water at any period of the year will afford no guide whatever as to its wholesomeness. Therefore, to lay the chief stress on its presence or absence alone would be unscientific and misleading. It would be equally misleading to place reliance upon any couple of dozen samples of water drawn from the mains of the companies, and from the analyses of these, assert that the Thames throughout its course of forty miles was entirely free from organic matter. This indeed, is an utter impossibility, for is it not a fact that hundreds of thousands of human beings daily and hourly contaminate the river, and who could venture to point out at what particular spot the faecal discharge of some typhoid case, or in summer time, some cholera patient, has passed into the stream, and thence into the company's reservoir? The several gradations between a good and bad water are almost infinite, and it is obviously quite impossible to set up a standard immunity from danger. This may be inferred from the fine line drawn by Dr. Tidy himself, who says, that "water pure enough for drinking should not require more oxygen to oxidise the organic matter present than from 0.05 to 0.15 part for 100,000 parts, that if the amount rises to 0.21 part the water is of very doubtful purity, and if above this, the water must be considered as decidedly impure." "Here he furnishes an instance," as Mr. Ekin, in his manual upon "Potable Water," somewhat sarcastically remarks, "and the only one of the kind on record, where half as much again makes all the difference between a dose that is safe and one that is unsafe. Or to put it in another way, in the case of an infected water, *six typhoid germs are harmless whilst nine would be hurtful!*"

We find it stated, also on the authority of another eminent chemist, that "there is no human method by means of which the precise actual weight of organic matter can be determined, much less is it possible to say how much or how little of the same is likely to prove injurious to health." In the face of an overwhelming amount of evidence that water containing from 0.9 to 1.0 part per 100,000 parts of nitrogen as nitrates, is a positively dangerous water, we cannot be expected to rely solely upon a chemical analysis. At all events the burden of proof rests with those who continue to assert to the contrary, and until this part of the question is fairly disposed of it is manifestly wrong to ask the public to believe this or

that water is, in every respect well fitted for the supply of the metropolis."

For our part we would much rather fall back upon the medical inspectors of the Local Government Board whose experiences have been gathered in quite another way, and who so far as we can gather from the reports, believe with us, that a good drinking water should, like Cæsar's wife, be above suspicion.

## Notes on Current Topics.

### The Mortality of Foreign Cities.

It is interesting occasionally to glance at, and compare, the vital statistics of other countries, especially at a time when the death-rate at home has risen so considerably from atmospheric and meteorological circumstances. Of course a comparison for a single week is valueless from a statistical point of view, as the changeable nature of surroundings influence so materially the results; and to arrive at a just conclusion we can only take the yearly returns. Still, we cannot but deplore the unusual fact that less than a fortnight since there were four cities in the United Kingdom—Glasgow, Liverpool, Manchester, and Dublin—whose death-rate was as high as any of the cities of the world. That notoriously unhealthy city St. Petersburg stood 10 lower than Dublin and Manchester; Liverpool was equal with Calcutta; and Glasgow above Buda-Pesth.

From the same official sources other interesting items may be culled. Thus, we have Paris with a much higher death than birth-rate; although in the aggregate its mortality does not stand so high during the corresponding week as any of the cities mentioned; it has, nevertheless, the ominous figures against its fair name, of 32 deaths from small-pox, 50 from typhoid fever, and 42 from diphtheria. Calcutta, too, gives the proportion of one-third the whole of its deaths to fever, while St. Petersburg yields one-tenth of its loss to typhus alone. The death-rate in New York is also very high, far beyond any other American city, diphtheria being credited with about one-thirteenth the total. London and Edinburgh still maintain their pre-eminence for health of all the important cities of the world, whilst Dublin and Perth stand at the bottom of the list.

### Case of Hydrophobia at Keighley.

We regret to have to refer to another case of this disease reported at Keighley, Yorks. The patient, John Loftus, æt. 22, was bitten about six weeks ago by a stray dog, which was shortly after shot. Symptoms of hydrophobia developed on Feb. 1, and he died on Feb. 3. Dr. Hartnett, who at once recognised the malady, asked Dr. Dolan, of Halifax, to see the case in order to verify the diagnosis and suggest some line of treatment.

The patient was in very poor circumstances, and great difficulty was experienced in obtaining persons to watch this unfortunate sufferer, and had not Dr. Hartnett, at great loss of time and by pecuniary aid, assisted the family, the circumstances of the case would have been much aggra-

vated. Treatment had to resolve itself into very simple and narrow limits.

It may be asked, Why was the patient not removed to a hospital? This was suggested and opposed by the friends and by the patient, though Dr. Hartnett offered to find the necessary funds for this purpose.

We are astonished to hear that Keighley does not possess a public subscription hospital. Such a large and wealthy town ought to have one. We trust some of the local surgeons will take the initiative and set such a scheme afloat. This is the second case of hydrophobia reported from Keighley, and we have pointed out so repeatedly the necessity of some stringent dog act that it seems almost useless to insist on such a measure. When a bishop or a duke shall be bitten by a rabid dog or die of hydrophobia, we shall then expect some legislation.

### Proposed Medals for Sanitary Work.

THE Society of Arts in order to encourage a sounder and more healthful system of house building, have decided to offer for competition three silver medals for "plans showing the best sanitary arrangements in houses built in the Metropolis, such plans to be exhibited in the Society's Rooms, Adelphi, in June, 1881, and to be sent in or before May 12, 1881."

1. One silver medal will be awarded for the best sanitary arrangements carried out and in satisfactory working in a house let out in tenements to artisans for which a weekly rental is paid.

2. One silver medal for the best sanitary arrangements in actual satisfactory working in a house of the yearly rental of from £40 or less to about £100 in value.

3. One silver medal for the best sanitary arrangements in actual satisfactory working in a house of the yearly rental value of £200 and upwards to any amount.

The houses may be old, fitted with modern sanitary arrangements, or may be new, and must be open to the inspection of the judges, who, in considering their award, will be guided by the suggestions of plans for main sewerage, drainage, and water supply, made under the Public Health Act, 1875. The houses must have been in actual occupation within the last three months, and a certificate must be given by the occupiers, on a printed form, stating the satisfactory working of all the sanitary arrangements, such form to be obtained at the Society of Arts.

### To Terminate the Chloroform Narcosis.

A PECULIAR device is mentioned by Schirmer in the February number of the *Centralblatt f. Augenheilkunde*. He claims to have used it in his clinic for many years, and often succeeded in producing inspiratory movements when other means failed. He also employed it to induce rapid recovery, for instance, in strabismus operations, in order to test the result. The method consists in irritating the nasal mucous membrane. It has long been known, at least to physiologists, that the fifth nerve retains its sensibility longer than any part in narcosis, and that reflexes may be induced through this nerve when other irritations fail. Schirmer uses simply a rolled piece of paper, which he turns in the nose. In dangerous cases he dips the paper into ammonia.

### The Vaccination of Paupers.

MR. PETER TAYLOR, ever ready to ride his pet hobby horse, anti-vaccination, got decidedly the worst of an argument with Mr. Dodson, President of the Local Government Board, in the House of Commons on Thursday. Mr. Taylor had, in fact, discovered a mare's nest, and in reply to his questioning as to whether he had sanctioned a resolution of the Holborn Board of Guardians under which relief would be refused to all paupers who had not been vaccinated, Mr. Dodson said he had not sanctioned any such resolution, nor had the Holborn Board passed one to that effect. In view of the spread of small-pox a recommendation was made to the guardians that medical officers when examining paupers should ascertain whether they had been vaccinated, and if not that they should be vaccinated as early as practicable. To make such a condition of relief as the question stated would be absolutely illegal.

### Visitation of Examinations.

WE learn that Dr. Gairdner, of Glasgow, Mr. Teale, of Leeds, and Mr. William Stokes, of Dublin, have been appointed to visit, on behalf of the General Medical Council, the examinations of the Colleges of Surgeons of the three divisions of the kingdom. We hail with satisfaction the selection of a court of visitors independent of Medical Council influences, and we have every confidence that gentlemen so high in public estimation as those we have named, will return to the profession a thoroughly honest verdict, founded upon a careful and vigilant inquest upon these examinations. If they do so they justify their appointment, and will not inflict upon the profession the series of polite platitudes which formed the staple of the reports of the first visitors appointed by the Medical Council.

### The Consulting Physiciancy of the Rotunda Lying-in Hospital.

THE election to this office which took place on Friday last, was regarded with much interest by the profession. After the death of the late Dr. Hudson it was known that the successions to the vacant office would be contested—an almost unprecedented occurrence, inasmuch as the Governors, in whom lie the choice of a consultant, had heretofore on all occasions acted upon the recommendation of the Master of the hospital. On the present occasion, however, Dr. Little, Professor of Practice of Medicine in the Royal College of Surgeons, whose nomination was supported by the master, Dr. Atthill, was opposed by Dr. MacDonnel, Physician to the Queen, and whose election was moved by two lay governors; also by Dr. Henry Kennedy, recently Physician to Cork Street Fever Hospital, and eventually Dr. Little was elected. The circumstance is worthy of notice irrespective of the professional merits of the respective candidates, because it asserts the principle, which we think ought to influence strongly the choice of a consultant to such an institution, that the physician who is to consult ought to have an influential voice in the appointment of the physician with whom he is to consult.

Without depreciating the qualifications of either of the unsuccessful competitors for this honorary office, we hold

the opinion that Dr. Little, as being the physician desired by the Master of the institution, had a pre-emptive right to consideration, and we are glad he was selected by the governors.

#### A New Medical Knight.

THE Queen has signified her intention of conferring the honour of knighthood on the President of the Royal College of Physicians, John Risdon Bennett, M.D., who retires from the chair in the present year. It will, we feel sure, be felt that Dr. Bennett is well deserving of a recognition of the amiable and excellent way in which his duties to the profession have been discharged during his tenure of office; and we congratulate him on the appropriate manner in which he is about to be rewarded.

#### Actions for Libel.

BESIDE the action pending in the Court of Queen's Bench against Dr. Hoggan and the publisher of the *Medical Press*, there are two others likely to excite much interest in medical circles, which will probably be disposed of in the after-sittings of next term in Dublin, and in the County Assize of the same date for Tyrone. In the first of these actions, our contemporaries, the *British Medical Journal*, and the *Cork Constitution* are to be the victims of actions for libel on the part of Mr. James Crawford, the Cork schoolmaster, whose unwarrantable attack on Dr. H. M. Jones in regard to the use of pilocarpine for the treatment of his child, who died of scarlatina in the Cork Fever Hospital, will be fresh in the minds of our readers. Our contemporaries, in common with ourselves, and every other medical journal of any character in the United Kingdom, criticised the charges against Dr. Jones, and animadverted on Mr. Crawford's conduct, and the vindictive manner in which the attack on Dr. Jones had been pursued. Since the decision, which exonerated Dr. Jones, was delivered by the governors of the Fever Hospital, Mr. Crawford, whose mental balance would seem to have been entirely upset by his family bereavements, has devoted himself to the posting of the dead walls of Cork with placards, which were none the less injurious to Dr. Jones, because they were obviously the emanations of a prejudiced mind, and now he seems to have succeeded in inducing a solicitor to take his fancied grievances into the courts of law. While the case is *sub judice* we can only express our hearty sympathy with the *British Medical Journal*, the *Cork Constitution*, and especially with Dr. Jones, in the persecution of which he is the victim. The second action is one for a libel upon Dr. Kinkead, Professor of Obstetrics in the Galway College, said to have been contained in a letter addressed by Dr. Valentine Browne, surgeon to the County Infirmary, to Dr. Pye, professor of anatomy in the same College. Dr. Kinkead had, for several years, delivered clinical lectures, with consent of Dr. Browne in the County Infirmary. Dr. Colahan had been subsequently admitted to the same function, an arrangement being come to with Dr. Browne on the subject of fees. This arrangement Dr. Browne has subsequently repudiated, and the alleged libel is contained in a letter in which he sets forth his reasons for excluding Dr. Kinkead in terms which that gentleman considers actionable, and, accordingly, he has brought his

suit in order that his professional reputation may be set right. Last week, the question whether such a communication, assuming it to be libellous, was privileged, was argued before the Court of Exchequer in Dublin, and judgment was given against Dr. Browne, so that the case will probably be heard on its merits next term.

#### American Opinion on English Asylums.

DR. GEORGE M. BEARD, M.A., member of the National Association for the Protection of the Insane, has republished, as a small pamphlet, an article he contributed to the *Boston Medical and Surgical Journal* for December 23 last, on "The Asylums of Europe." In this he describes the chief characters by which those institutions in England are marked, and expresses unhesitating approval of the system he has seen in use. He draws especial attention to the comparative—in places almost absolute—freedom enjoyed by inmates of the institutions, and on the absence of all methods of restraint. He is of opinion that the Americans can learn much by a study of Continental systems of treatment, and advises this rather than simple imitation. One passage we will venture to quote, and we believe it will meet with the hearty assent of English physicians:—"In the treatment of the insane outside asylums by general practitioners and students of the nervous system, there has been probably as much advance in this country as abroad; and especially in the treatment of various morbid states of the nervous system, that often lead to insanity, there has been nowhere such satisfactory progress as here. This is the philosophical method of combating insanity; treating the insane before they are insane; arresting candidates for lunacy before they have stepped on the threshold of the asylum."

#### Chlorine not an Element.

PROF. MEYER, of Berne, by a series of experiments conducted on chlorine gas, has demonstrated that the assumption of its elementary character is incorrect, and that it is in reality an oxide of a metal, to which he proposes to give the name *murium*. The method adopted in arriving at this conclusion is that of dissociation at high temperatures; 700° C. sufficed to dis sever the oxygen from its associated element, and having collected the former by passing the mixture through a bath of mercury, its presence could be demonstrated by the usual tests. The metal *murium* formed an amalgam with the mercury, but it has hitherto been too minute to permit any adequate examination of its properties to be made. It is fairly open to conjecture that the elements iodine and bromine, hitherto classed with chlorine, may likewise be found, when submitted to a similar series of experiments, to be compound bodies; and it may reasonably be supposed, further, that all such discoveries will have an appreciable bearing on the importance attaching to the chemical processes of animal life. The discoveries must, in any case, have an interest for the physiological chemist, especially since well-known authorities in this country are disposed to credit the announcement made by Prof. Meyer. We are not unlikely soon to hear a good deal more concerning the new element.

### The Seamen's Hospital, Greenwich.

THE Earl of Northbrook will preside at the sixtieth annual court of the Seamen's Hospital Society to be held this day at Willis's Rooms at 3 p.m. Several well-known gentlemen have promised to address the meeting, to which admission is by ticket only. The occasion will possess special interest from the fact that opportunity will be taken at it, of presenting an address from the committee of management of the hospital, to Mr. Henry C. Burdett, who has for a long time acted as secretary, and now retires from office. Mr. Burdett's valuable services in connection with the institution, and the care of hospitals generally, will make the ceremony an interesting one to many persons.

### Death of Mr. Carlyle.

Few will fail to feel keen regret that one of England's greatest writers is no more. Mr. Thomas Carlyle died on Saturday at his residence in Cheyne Walk, Chelsea, after a not long illness, the chief characteristic of which was sheer prostration. The termination of Mr. Carlyle's life was in the nature of things, to be anticipated at any moment, and of late the increasing evidences of old age left little expectation that he would long survive. The recent severe weather has undoubtedly served to hasten the end a little, which, however, has been evidently approaching for some time. Though 86 years of age, Mr. Carlyle was still vigorous up to last summer, when increasing feebleness rapidly set in, and ended on Saturday in death.

### Amendment of the Artisans' Dwellings Act.

SIR RICHARD CROSS has given notice that he will move, "That a Select Committee be appointed to consider the working of the Artisans' Dwellings Act, 1875, and the amending Act of 1879, with a view of considering how the expense of carrying out these Acts may be reduced, and also of considering any causes which may have prevented the reconstruction of dwellings for the artisan class to the full extent contemplated and authorised by these Acts, and of recommending such amendments as may be most expedient for carrying out the full intention of these Acts; and also to consider the working of the Metropolitan Streets Improvements Acts, 1872 and 1877, with the same objects." In the event of Sir R. Cross not being able to secure a debate on his resolution, it is understood that he will ask for the Committee without discussion.

### Statistics of Medical Journalism.

On the authority of M. Dureau, one of the librarians of the Académie de Médecine, the present number of medical periodical publications for France and its colonies is 147, 95 of these being published in Paris, and 52 in the departments. The German Confederation publishes 133 journals, Great Britain 69, Austria 54, Italy 51, Belgium 23, Spain 26, Russia 26, Holland 16, Switzerland 10, Sweden and Norway 9, Denmark 5, Portugal 4, the Danish Principalities 4, Turkey 2, Greece 1—the total for Europe being 583. In America there are 183 journals, in Asia 15, in Oceania 4—the total for the various Continents being 785. The number of medical journals created since 1679 exceeds 2,500.

### The London International and Medical Sanitary Exhibition, 1881.

CONSIDERABLE progress has been made with the arrangements for this exhibition, and since the publication of the first list of the guarantee fund the following additions have been received:—Messrs. Burroughes, Wellcome and Co., £30; Robert Rawlinson, Esq., C.B., £25; Sir James Paget, Bart., F.R.S., £10 10s.; T. J. Smith, Esq., (Hull), £10; Messrs. Strode and Co., £10; Messrs. Woollams and Co., £5 5s.; John Carter, Esq., £5; Messrs. Meyer and Meltzer, £5; W. A. Meredith, Esq., £5; the Sanitary Engineering Company, £5; Daniel T. Bostel, Esq., (Brighton), £3; William Martindale, Esq., £2; Alfred E. Fradelle, Esq., £1 1s.; and Messrs. Walter Macfarlane and Co., £25. In addition to the Medical and Sanitary Sections there will be a Miscellaneous Section, consisting of school furniture and other articles more or less connected with the general purpose of the exhibition. Applications for space are to be sent in not later than Thursday, March 31st, 1881; but from India, the Colonies, and America applications will be received up to April 15. Full particulars may be had on application to the Secretary, Mr. Mark H. Judge, Parkes Museum of Hygiene, Gower Street.

### Eucalyptus Oil in Antiseptic Dressings.

DR. SIEGEN writes very favourably (in *Deutsche Med. Wochenschr.*) of oil of eucalyptus as an antiseptic, its special advantage being that it shows no tendency to cause eczema, or to irritate the skin in any way. The solution employed by Siegen was made by dissolving three grammes of the oil in fifteen grammes of alcohol, and adding 150 grammes of water; this quantity is enough to moisten thoroughly one metre of well-washed gauze. The dressing is applied wet, and covered with gutta-percha tissue; it may remain without changing for 3—5 days. It is noted that in one case an eczematous eruption, which had been caused by a thymol dressing, healed under the eucalyptus dressing in a few days.

### Tuberculosis and Scrofula.

IN a discussion on the relations of tuberculosis and scrofula at the last meeting of the Société Médicale des Hopitaux of Paris, M. Labbé said that he had arrived at the conclusion that tubercle is a termination of scrofula, as it may be of other diseases. M. Ferraud's opinion inclined to the same conclusions. Scrofula, he said, is not the only constitutional disease where we find tubercle; arthritic patients also show tubercles; phthisis, therefore, may not follow the scrofulous diathesis. To seek in tubercle a special lesion peculiar to a special disease is a precarious work, as Dr. Cornil says. Tubercle is a morbid product which may follow all maladies without belonging peculiarly to any of them.

### A New Treatment of Orchitis.

DR. SABADINI recently communicated to the Society of Medicine of Constantinople the case of a patient suffering from blennorrhagic orchitis whom he had very successfully treated with iodoform. An ointment was applied to the tumour consisting of 4 grammes of iodo-

form to 40 grammes of vaseline. The effects were remarkable; the pain rapidly disappeared, the patient did not have to refrain from his work, which obliged him to stand all day, and the swelling disappeared in eight days.

IN consequence of the extreme severity of the weather throughout the United Kingdom, the death-rate rose to unusual proportions the week before last, especially in Glasgow, Liverpool, Manchester, and Dublin; the increase being chiefly confined to deaths of old people and children, and to those suffering from affections of the respiratory organs.

THE next quarterly meeting of the British Medical Temperance Association will be held in the Medical Society's Rooms, 11 Chandos Street, Cavendish Square, on Friday, February 11th. The President, Dr. Richardson, F.R.S., will take the chair at 4 p.m., and a paper will be read by Dr. G. B. Clark on "Ava, the Polynesian Intoxicant: its Physiological Action and Therapeutical Uses."

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 were—Leicester 18, Sunderland 21, Bradford 23, Newcastle-on-Tyne 24, Hull 26, Brighton 26, Portsmouth 27, Leeds 27, Sheffield 28, Plymouth 28, Bristol 28, London 29, Norwich 30, Edinburgh 31, Birmingham 32, Wolverhampton 34, Oldham 34, Salford 36, Nottingham 38, Glasgow 39, Liverpool 40, Manchester 46, and Dublin 47.

IN the large towns last week scarlet fever showed the largest proportional fatality in Oldham, Sunderland, and Sheffield; and whooping-cough in Liverpool, Glasgow, and Leeds. The death-rate from fever (principally enteric) was again considerably below the average, with the exception of Dublin, where 15 deaths were recorded. Of the 30 deaths from diphtheria in the large towns 14 occurred in Glasgow, 8 in London, and 4 in Edinburgh. Small-pox caused 53 more deaths in London and its suburban districts, one in Birmingham, and one in Plymouth; no fatal case was recorded in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

EDINBURGH EYE INFIRMARY.—The annual meeting of the subscribers to the above institution was held last week. Mr. A. P. Purves, F.R.C.S. Ed., treasurer and secretary, submitted the report of the managers, which stated that since the re-opening of the charity twenty-eight years ago 25,176 individuals had applied for advice, of whom 397 had been received as in-patients. A large proportion of the cases were, as might be expected, of a severe character, many of them having been for some time under previous treatment. It appeared from an abstract of the accounts that last year the receipts were £104 11s. 0½d., and the payments £83 2s. 1d., the whole of the officers of the institution acting gratuitously. The secretary added that during the past year there had been a decrease

of £16 11s. 7d. in the subscriptions of the public, which the office-bearers hoped would be made up during the ensuing year. The report was adopted, and the officials re-elected.

GLASGOW LOCK HOSPITAL.—The seventy-fifth annual general meeting of the contributors and subscribers to the Glasgow Lock Hospital was held on the 25th ult., when Lord Provost Ure occupied the chair. It appeared from the directors' report, which was submitted by Mr. R. Young, the hon. secretary, that during the year there had been an increase in the number of admissions over the previous year to the extent of 42. On the 1st January, 1880, there were in the hospital 29, and there had been admitted since 385, making in all 414. Of these there had been dismissed as cured 390, leaving under treatment on 31st December last 24. The average time each patient remained in the house was 26 days. The average cost of each patient dismissed cured was 34s. 6d. The returns showed that by far the largest number of the patients were young persons, the average age of whom did not exceed 21 years.

UNIVERSITY OF EDINBURGH.—ATTENDANCE ON THE CLASSES.—There must be something wrong in the method of testing the attendance of students at the classes of the University of Edinburgh, when a student can fail to attend nine lectures out of ten, and no notice be taken of his absence. The system of "card-calling" is a farce, for it is well known that a few shillings judiciously spent at the beginning of the session will ensure all "cards" being in. Some of the professors object to card-calling, and would trust to the honour of the student for his regular attendance. The present system is demoralising, and has a most disastrous effect on some students, who are sadly in want of a more powerful incentive to work than the promptings of honour.

JOHN DUNCAN, THE WEAVER BOTANIST.—We have much pleasure in directing attention to the movement recently inaugurated to place this remarkable man above the cold charity of the parochial board. While earning his living as a handloom weaver, John Duncan has succeeded in forming a very fine collection of the most characteristic plants of Scotland, from the English border to the Moray Firth. His knowledge of botany is scientifically thorough and wonderfully wide, and his collection is therefore of much scientific value. Only the other day he presented about 1,200 of his specimens to the University of Aberdeen. Duncan is now upwards of 80 years of age, and through sheer decay is no longer able to earn his living: he has therefore been compelled to seek parish relief, which must be peculiarly galling to one who has hitherto led so independent a life as he has. An attempt is being made to collect a small sum to enable John Duncan to pass the remainder of his days in comfort. For this purpose a subscription has been opened in *Nature*, and subscriptions sent to the editor of that publication will be duly forwarded to the proper quarter.

AUSTRALIA.—LEGISLATIVE ASSEMBLY.—We notice in the daily press that at a recent meeting of the Australian Legislative Assembly a Mr. L. L. Smith tabled a motion. At the same time a Melbourne quack doctor of this name befouls the Colonial press with his abominable bird-lime. Will any of our Australian readers inform us if the two individuals are identical? If so, Hibernian turbulence and unrest notwithstanding, we must confess they manage these things better in the "old country" after all.

OBAN HILLS HYDROPATHIC SANATORIUM.—We are pleased to learn that this enterprise continues to make steady and satisfactory progress. We have long regarded it as a mis

fortune that Oban has not been appreciated to the extent that it deserves as a health resort. Owing to the influence doubtless, of the Gulf Stream, its climate is peculiarly mild during the winter and early spring. Recently, as we can testify from personal experience, while the inhabitants of Glasgow were living in Cimmerian darkness, and more than Cimmerian cold, and suffering so extensively from chest diseases in consequence, the inhabitants of Oban, even during the most intense period of frost, enjoyed a perfectly pure atmosphere, and on the occurrence of the thaw, as genial and balmy an atmosphere as existed in any portion of these islands. Were this fact as well known as it should be, now that the public command the facilities of travelling by rail, we are firmly persuaded that a visit to Oban would not be deferred until the too late period of the year at which it is usually undertaken. The site of the new hydropathic establishment is simply magnificent, and we wish the project the success to which it is so justly entitled.

**THE GLASGOW ROYAL INFIRMARY.**—The annual general meeting of this institution was held last week under the chairmanship of Dr. Wm. McEwen. The report of the superintendent (Dr. Thomas) stated that 5,117 patients had been admitted to the hospital during the year, being 195 less than for the previous year. The daily average number resident was greater, being 503, as against 437 in 1879. The number admitted in the medical wards during the year 1880 was 2,352. The mortality in these wards was 12·7 per cent., against 12·2 in 1879, and 13 in 1878. In the surgical wards the number admitted during the year was 2,765. The mortality in these wards was 6·4, against 5·2 in 1879. In the whole institution the number remaining on 31st December, 1879, was 476. The number admitted during 1880 was 5,117, making a total of 5,593. Deducting 509 remaining on 31st ult., the total number treated to a conclusion was 5,084, of whom 4,610 were dismissed, and 474 died. The total mortality of the patients treated to a conclusion was 9·3 per cent., against 8·6 in 1879, and 8·8 in 1878. The treasurer's statement showed that the ordinary revenue amounted to £18,125 11s. 6d., and the ordinary expenditure to £25,548 16s. The extraordinary revenue was £10,168 19s. 5d., while the extraordinary expenditure was £6,816 6s. 1d., the balance of expenditure over income being £4,070 11s. 9d. The chairman, in moving the adoption of the reports, said that if they had gone upon the principle of only providing hospital accommodation where the public, by increased subscriptions, had enabled them to defray expenses, they could not, during the past year, have given accommodation to more than two-thirds of those who had been treated. He hoped there would be a more generous response to the appeal of the directors for funds which would support the institution in all time coming. Professor Gairdner said that from his experience of the medical department, he could assure the public that the additional money had been most profitably spent, and he appealed to the public, especially to the middle classes, to be more generous than they had been in the past. The reports were adopted.

**DEATH FROM BLOOD-POISONING.**—On the 2nd inst., Mr. Richard Tud, draper, Leith, was buried in Rosebank Cemetery there; death having occurred under the following circumstances:—A few days previously he cut his finger with a piece of glass, and wrapped a piece of tissue paper over the wound. Blood-poisoning ensued, and death took place in a few days.

**EMPIRICISM CONFIRMED BY SCIENCE.**—To anyone interested

in medical archaeological lore, a rich mine of interesting material exists in the numerous Gaelic manuscripts, still existing in the Advocates' Library, Edinburgh, and elsewhere. These manuscripts are written in latin, and by practitioners educated, for the most part on the continent, and ignorant, we may tell the vain-glorious southerner, of the English language. It is interesting to note, possibly as a survival from our Gaelic physicians, that a popular cure for dyspepsia, not long ago, in the Highlands, consisted in the lining membrane of the gizzard of the cock, dried and powdered. Is this a case of the confirmation by science of empirical experience and observation?

**DEATH-RATE OF GLASGOW.**—The almost unprecedented severity of the present weather has naturally affected the death-rate. For the week ending with Saturday the 29th ult., the death-rate of Glasgow was 39 per 1,000 per annum of the population, as compared with 36 in the preceding week and 26 in the corresponding period of last year. The cold has told severely on the aged and infirm. An increase of over 50 per cent. in the death rate has thus occurred.

## Literature.

### THE SCIENCE AND PRACTICE OF MEDICINE. (a)

No language can in modern days compare as to universality with the English tongue, which is employed as a medium of daily civilised inter-communication throughout the vast colonies and dependencies of the British Empire, as well as in the United States of America; and as a consequence, a standard work in that language enjoys a cosmopolitan circulation, which its German or even its French congener cannot possibly approach. The circulation of British works of eminence, in any department, is further increased in a manner more flattering to the vanity of their authors than conducive to their material interests, by our Transatlantic cousins, who, the moment such works appear, inundate the American market with cheap reprints generally at as many cents as the British orthodox copy costs shillings; and this circulation in the new hemisphere becomes practically illimitable. Aitken's "Science and Practice of Medicine," had been now before the public for twenty-two years; and each succeeding edition has been received with increasing favour—in fact, it would not be too much to say that it has been for this long time past in the hands of almost every English-speaking and reading physician in the world. To attempt an ordinary review of a work upon which the hall-mark of public favour has been so unmistakably impressed, is obviously unnecessary, and the more so as each of the six previous editions have been already noticed in these columns at the time of their several appearances. We shall content ourselves with pointing out the special features of the seventh edition now before us, the issue of which became necessary from the fact of the work being long since entirely out of print.

We have carefully perused the two large volumes, and find them not so much a reprint as practically a new work in every portion where any changes have taken place. The number of pages remain nearly the same, but the lines have been widened, and made to contain a larger number of words; and this small increment in each page introduces, in over 2,000, a great mass of new matter. No department of medicine has made such strides as the diseases of the brain and nervous system, in which a new edifice has been built by the labours of Charcot, Hughlings-Jackson, Clifford Allbutt, Gowers, and others; and, accordingly, we find this section entirely newly written, and nowhere could the busy practitioner find a better or clearer statement of the present condition of this great department of medicine, or of the ophthalmoscopic or other aids to diagnosis. Diseases of the throat and larynx are fully described, and the labours of Morell Mackenzie and others fully set forth; and the section upon diseases of the kidney is admirably and efficiently worked out. The chapter upon the geographical distribution of disease is readable and

(a) "The Science and Practice of Medicine." By William Aitken, M.D., F.R.S. Seventh Edition. London: Charles Griffin and Co. Royal 8vo, pp. 2,331.

instructive, and is made clear by a very fine map; and the whole work is illustrated with carefully executed woodcuts, wherever these are required to explain the text. Last, and not least, the volumes are distinguished by very great typographical accuracy, and are furnished with a copious index, which enables the reader to at once localise any subject upon which he wishes to inform himself.

The great merit of Aitken, in our opinion, is the intermediate position which it occupies between the colossal work of Ziemssen, and the short treatises of Bristowe, Niemeyer, Bartholow, and Watson. Any of these latter works affords a brief view of the leading outlines of most departments of the healing art; and any one of them can be read through in a few days. As books of reference, however, they are not satisfying even to the advanced student, and still less to the practitioner—in fact, they were never intended for any such purpose. The great price (£16) of Ziemssen's "Medical Cyclopædia," effectually puts it out of the reach of the ordinary practitioner; but anyone who possesses it, and who turns to it for information upon any subject which he desires to study or teach, will usually find everything that can be said upon that subject. In Lord Beaconsfield's recent novel, "Endymion," one of the literary characters is a gentleman who is delineated as very "fond of reading Encyclopædias;" but we suspect that so untrusting a student exists only in the imagination of the noble author, and we frankly confess that, although we have frequently consulted them, we have not read through the sixteen volumes of Ziemssen, nor do we think it likely that we shall be able to do so. Here it is that Aitken fills up [a distinct want by two large volumes, which any industrious reader can carefully peruse and assimilate in the evenings of a month; but which, at the same time, if consulted as a book of reference, will yield him copious details upon almost any subject, and in fact supply most of the information necessary for the ordinary principles of daily medical work. We have had the advantage of inspecting Netley Hospital and Medical School, with its splendid laboratories, museums, and other facilities of study; and we are glad to see Professor Aitken employing them so well in bringing his great compilation to its present high standard of efficiency and completeness. We cordially re-echo the opinion of our contemporary, the *Edinburgh Medical Journal*, that "there is perhaps no work more indispensable to the practitioner and the student;" and as such we cordially commend it to our readers.

Q.

#### A MOVABLE ATLAS OF THE MALE ORGANS OF GENERATION AND REPRODUCTION. (a)

THIS is one of the now well-known Atlas series, published by Dr. Witkowski. By means of a series of movable coloured layers of paper, it shows the various structures which make up the male organs and the perinæum. The view thus given is a very good one, and is quite sufficient for the student who happens to be reading anatomy when dissection is over. The Atlas will be found most useful for demonstration of parts during clinical instruction. The accompanying letter-press, translated by Dr. Campbell Black, contains some curious information, and is written in a very pleasant style; but it is not as full and definite either in physiology or anatomy as would suit any student preparing for examination.

#### THE FUNCTION OF VISION AND ITS ANOMALIES.

IN our review of Girard-Toulon's work, translated by Mr. Lloyd Owen, F.R.G.S.I., page 81 (Jan. 26), by the omission of the word *not*, and the transposition of another word, a quotation that excellent monograph, which was intended to convey from an example of the lucidity of Mr. Owen's translation, became somewhat involved. It should run thus:—"In a high degree of hypermetropia, the long accommodative efforts, by congesting the deep membranes, frequently induce a certain degree of amblyopia. And the amblyope no longer seeks clearly defined images; what he desires are large images, and these are not obtained but by increased approximation of objects, by which means the retinal pictures enlarge much more rapidly than the circles of diffusion."

(a) "A Movable Atlas of the Male Organs of Generation and Reproduction." By G. J. Witkowski, M.D. The Text translated by Dr. D. Campbell Black. London: Baillière, Tindall, and Cox.

## Correspondence.

### THE TREATMENT OF LOCOMOTOR ATAXY BY PHOSPHIDE OF ZINC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Phosphide of zinc ( $P_2 Zn_2$ ) is a medicine not (if I don't mistake) much employed in England, although its properties as a nervous tonic have been demonstrated by such men as Ashburton, Broadbent, Thompson, Hammond, and others. Perhaps this is due to its comparatively recent discovery (1874), or that medical men were slow to publish the results of their observations. Its properties as a stimulant to the nervous system can be no longer doubted, it having been prescribed with success in such nervous diseases as hysteria, neuralgia, mercurial and alcoholic paralysis, incontinence of urine, hyphochondriasis, and has acted efficaciously in chlorosis, anaemia, and amenorrhœa, &c. But there is another disease for which I consider it, if not a specific, yet the only remedy that has given real and permanent satisfactory results. I mean progressive locomotor ataxy. This disease is well known to be most rebellious to treatment, as the variety of remedies employed testify, some medical men of authority even admitting their incapability to check its progress. The following cases which I have actually under treatment may be of interest as they encourage the idea of a real and radical cure. The first is that of a man about fifty years of age, who being out in the Crimean War, lay down one night on the ground covered with snow and slept for some hours. On awaking, he could not move, as he was almost frozen, and had to be carried to his tent, where for some days he remained in a critical state. But he got over it, and was enabled to finish the campaign; and not so two of his companions, who were lying with him the same night, as one was found dead in the morning, and the other had to undergo amputation of both feet. On his regiment returning to France he abandoned military for civil life, and became a commercial traveller. Soon after he perceived a certain unsteadiness in his gait, especially in the evenings. Thinking it was the effect of indulging too freely in stimulants, he confined himself to a more soberly regime, but the phenomenon persisting, he consulted a doctor, who ordered him some baths. But the insidious disease refused to be checked by such mild treatment, and now lancinating pains commenced to be felt, especially at night. He changed his medical adviser, and this time his disease was recognised, and he was prescribed strychnine and the cold *douche*, from which he received some benefit, but it was only transitory. Hearing of the celebrated Charcot, he came to Paris to consult him. M. Charcot did not conceal from him his position, and gave plainly his prognosis which I need not add was not encouraging to the patient. However, he ordered him the actual cautery down the spine, nitrate of silver (afterwards changed to sulphate of zinc), and the cold *douche*. From this treatment he experienced some amelioration, but his resources failing him, having had to renounce his situation, he entered the *Hôtel Dieu*, where he was placed under the care of Duchesne; but he was not there a month when the war broke out, and soon after he had to leave in order to give place to the wounded. Ever since he has been confined to his room. The pain he suffered at night was excruciating, it being so capricious in its point of selection as it was severe. Locomotion was absolutely impossible, further, he lost all sense of touch. About three months ago I commenced giving him the preparation of zinc in question with the following result: almost complete cessation of pain, locomotion, although very difficult, was yet possible, the state of vision that had become seriously affected, more satisfactory. The sense of touch still blunted. The second case is that of an *artiste*, unmarried, about 40 years of age, who for the last five years is confined to her room. Ten years ago she first perceived symptoms of the disease, but as it did not hinder her from following her profession she thought nothing of it. However, the disease progressing, she sought medical advice, and was ordered iodide of potassium and the cold *douche*. She followed this treatment for a long time, and deriving no benefit from it she became indifferent, and for a year before I saw her she had abandoned all treatment. She had of course to renounce her calling. At the time I saw her locomotion, as in the first case, had become absolutely impossible, and she suffered so much every night that she disturbed the other lodgers with her cries. Sensation was intact. After

a month's trial of the phosphorus of zinc all pain had completely disappeared, and she was able to walk across the room unaided. In another month the amelioration was more marked. She was now able to take a walk in the garden, leaving on her servant. She still remained free from pain. She continues the treatment. The third case is that of a married woman, 37, who for the last three years has been affected with locomotor ataxy. Four months ago she came to me complaining of unsteadiness in her gait, so much so, that she was ashamed to go out in the street for fear the people might think she was drunk. She suffered acutely at all times but more especially at night. All work became impossible to her, as anything she took in her hands she let fall. She was still able to move about, but not unaided. I put her under the same treatment with a like result; complete cessation of pain, walks better, feels more firm on her limbs, sleeps soundly, incontinence of urine, with which she was troubled before, disappeared, spirits good, and certain of being cured. I see her every fortnight, and each time an improvement is noted. Now, Sir, the above cases encourage me to think that locomotor ataxy is amenable to phosphide of zinc, especially when taken *au début*. The form in which I have prescribed it is that of pills. I divided twelve grains into a hundred pills, and gave one every day for a week, and then two were given daily, and so one up to five, which number I never exceeded.

I am, Sir, yours &c.,

HASTINGS BUBROUGHS, L.R.C.S.I., &c.,  
Surgeon to English Dispensary, Paris.

January 4th, 1881.

#### ON THE ADVANTAGE OF FURNISHING CATHETERS AND HOLLOW SOUNDS WITH CLOSELY-FITTING BOUGIES INSTEAD OF WIRE STILETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In page 27 of your excellent Journal, there is an article headed—"On the Advantage of Furnishing Catheters and Hollow Sounds with Closely Fitting Bougies instead of Wire Stilets." By W. F. Teevan, B.A., F.R.C.S., Surgeon to the West London and St. Peter's Hospitals. The same principle has been adopted and proposed by me thirty-three years ago. In an article published in the *Medical Press*, Vol. xvi., page 369, A.D. 1847, I have therein recommended that a large catheter, in which another catheter is closely fitted in place of its stilet, be introduced into the urethra in cases of retention of urine, accompanied by injury of the urethra or by prostatic hæmorrhage.

The following extract from the article will clearly express my meaning:—"I took a gum elastic catheter of large calibre without a stilet and introduced into it, in the same manner as you would put your finger into a glove, another catheter armed with a stilet and of sufficient size to fill completely the larger one. I passed the double catheter with the greatest freedom into the bladder and had the happiness to find upon withdrawing the smaller one that the urine flowed in a full stream, at the same time giving my patient immediate relief from his protracted suffering."

The only difference in this plan from the one adopted by Mr. Teevan is, that I used a catheter instead of a bougie. The armed catheter certainly preserves the curve better than the bougie.

M. C. BERNARD, M.B. Dub. Univ.,

Dundrum, co. Dublin.

### Obituary.

#### DR. HAMILTON LABATT.

WE have to record the death of Dr. Hamilton Labatt, of Dublin, which occurred on Friday last, at his residence in Upper Fitzwilliam Street. Dr. Labatt was the youngest of twenty-two children of Dr. Labatt, a distinguished physician of the last generation in Dublin. He took the fellowship of the Royal College of Surgeons in Ireland in 1844, having previously graduated in arts in the University of Dublin. Shortly afterwards he was

appointed Medical Officer to the South City Dispensary, which he held until his death. For many years he held a seat on the Council of the Royal College of Surgeons. He was chiefly known to literature by his book on "Venereal," which, at the time of its publication was much esteemed, and was also the author of a work on "Restraint in Insanity." His genial disposition made for him many friends, and he died enjoying the respect of those with whom he had been publicly associated.

#### DR. JENCKEN.

AN unhappy mischance last week caused the death of Dr. Ferdinand Jencken, of Kingstown, co. Dublin. He, unfortunately, some time since inoculated himself with the virus from a case of malignant erysipelas, and was taken with pyæmia, from which, after ten days, he died. Dr. Jencken was an M.D. of St. Andrew's of 1853, and held also the membership of the London College of Physicians and Surgeons, and the license of the Irish College of Physicians. He had no public office, and his public writings consisted in various papers, on ozone and other subjects, in the medical periodicals, and a work on "Cholera and Vaccination."

### Medical News.

**Association of Surgeons practising Dental Surgery.**—The annual meeting of this Association was held on Wednesday, January the 26th, at 8.30 p.m., when the treasurer announced that the finances of the Society were in a most healthy condition. The retiring President, Mr. W. A. N. Cattlin, F.R.C.S., delivered an address "On the Imperfections of the Dentists' Act, with Questions as to the Alterations Required to Protect the Interests of Qualified Surgeons." The following is a list of the newly-elected officers of the Society:—*President*: Mr. T. Edgelow. *Vice-Presidents*: Mr. J. A. Baker, Mr. Samuel Cartwright, Mr. W. A. R. Cattlin, Mr. Francis Brodie Imlach, Mr. S. J. A. Salter, F.R.S., and John Smith, M.D., F.R.S. *Ed. Treasurer*: Mr. S. H. Cartwright. *Hon. Secretary*: Mr. J. Hamilton Craige. *Council*: Mr. Edward Bartlett, Mr. J. Fairbank, Mr. Francis Fox, Mr. C. Gaine (Bath), Mr. W. A. Hunt (Yeovil), Mr. W. D. Napier, Mr. W. G. Ranger, and Mr. Augustus Winterbottom.

**National Hospital for Consumption, Ventnor.**—At the annual meeting of the Governors held on the 2nd inst., under the presidency of Sir Harry Verney, Bart., M.P., the report recorded a continuance of the efficiency of the institution, and that an increased number of patients had been benefited by treatment at the hospital during the past year. The receipts for the year amounted to £7,216, and the expenses to £7,380. His Royal Highness, Prince Leopold, was elected President in succession to Viscount Eversley. The medical report was read by the Hon. Visiting Physician, Dr. Sinclair Coghill, and it stated that 598 patients had been treated at the hospital, the mortality being only 2.8 per cent.

**The Cancer Hospital, Brompton.**—The annual general meeting of the governors of this Hospital was held on the 2nd inst. From the Thirtieth Annual Report of the Executive, it appears that the operations of the charity have been materially assisted during the year by an increase of funds. The extension of the Hospital has been considered, and after very careful deliberation, it was decided to commence the additional buildings forthwith. For this purpose it was proposed to open a "special building fund" to avoid, as much as possible, encroaching on the regular funds. During the past year, 1,028 new patients were received, 339 being in-, and 689 out-patients.

#### TREATMENT OF DIPHTHERIA.

M. CREQUY, according to *La France Médicale*, commences his treatment of diphtheria by removing the false membrane with a forceps. He endeavours by a twist-

ing motion to remove the membrane, without breaking it, in as large a piece as possible; he then with a sponge dabs the denuded mucous surface with a solution of tannin. He never hesitates to adopt this method in all cases.

## NOTICES TO CORRESPONDENTS.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**SPECIAL NOTICE TO SUBSCRIBERS.**—The Publishers respectfully remind Subscribers that subscriptions for the past year are now due, and should be remitted for England and Colonies to the London office, for Ireland to the Dublin office, and for Scotland to the Edinburgh office.

**DR. LAUDOLT (Paris).**—Thanks, a note has been made of your request.

**FR. PANTALONI (Rome).**—We have directed our publisher to send you the missing numbers.

**DR. G. C. SMYTHE (Greencastle, Indiana)** is thanked for his note and enclosure.

**SAFE FOR THE PRESENT.**—Referring to the last act (for the present) in the life of that notorious diploma-monger, Dr. Buchanan, the *Students' Journal* says that he has been at last convicted on a charge of defrauding the Government of the United States, fined 500 dollars, the costs of the prosecution, and imprisoned for ten months. Probably the money will be paid with cheerfulness and thanksgiving, but the imprisonment will be a harder pill to swallow by the renowned doctor. He has had his day, and a good day too, so far as profits were concerned. It is to be hoped that in future, by the exercise of constant surveillance, the title of M.D. from across the Atlantic will be no longer considered at in Great Britain, but duly respected.

**A LUCRATIVE APPOINTMENT.**—In our list of "Vacancies," present number, will be found one for the southern district of the city of Durham, with an acreage of 4,816, population about 6,000, to which the municipal salary of £20 per annum for a medical officer is attached. We opine there will be a keen competition among educated gentlemen for the dignity of the position, added to its remunerative attractions.

**AN AUTHOR.**—The book has been out of print some years; but you could probably obtain a sight of it in the libraries of the Colleges of Physicians or Surgeons.

**DR. SUMNER.**—1. Shortly. 2. Will ascertain particulars and let you know by private note.

**CIVIL MEDICAL ATTENDANCE OF TROOPS.**—A correspondent writes: "I am an M.B.C.S.E. and dispensary medical officer, and for some years past enjoyed the monopoly of examining the militia recruits for the district. Of late they have been taken to a neighbouring practitioner, and, on inquiring the cause, was told that I had only a single qualification and my neighbour had the double. Therefore, according to the 'Medical Act,' he was entitled to them. Is this a valid reason for superseding me?"

[An army medical officer must have a double qualification, but the regulations which refer to civil medical practitioners in charge of troops ("Irish Medical Directory," page 835) contains no such provision, nor have we ever heard of such a requirement being made. As regards the legality of universal medical practice under the Medical Act, a technical question arises under sec. 31 of the Act, which declares that every registered practitioner "shall be entitled, according to his qualifications, to practise medicine or surgery," or both. It is still undecided whether these words forbid, technically, a physician from practising surgery, or vice versa: but, as a matter of fact, the right of a registered practitioner—whether he holds one or many diplomas—to practise all branches of the profession, has never been challenged. So far as we are acquainted with the regulations and the precedent which govern the question, we do not think that the lack of a second diploma has ever been held as a reason for ousting a practitioner already in office; but we cannot say that the Army Medical Department is not entitled to act on its own discretion, though we think it a very hard case that they should transfer the appointment under such circumstances.—Ed.]

**A NEW INTOXICANT.**—A meeting of the Medical Temperance Association will be held in the rooms of the Medical Society of London on Friday, Feb. 11, at 4 p.m., when a paper will be read by Dr. G. B. Clark on "Ara; the Polynesian Intoxicant, its Physiological Action and Therapeutical uses." Dr. Richardson, F.R.S., will preside over the meeting, to which all medical practitioners are invited.

**MR. J. HAMILTON CRAIGIE.**—Unfortunately, we cannot spare sufficient space. Mr. Cattlin's Address before the Association of Dental Surgeons would occupy ten or twelve columns of our type, and as the subject is not of sufficient interest to the majority of our readers, and we have, moreover, many regular contributors waiting for space, we regret our inability to comply.

**A PROVINCIAL PRACTITIONER.**—1. The English translation of Charcot's "Lectures on Bright's Disease of the Kidneys." 2. Aitken's "Science and Practice of Medicine." 3. Playfair's or Leishman's "Midwifery."

**THE SANITARY INSTITUTE OF GREAT BRITAIN.**—This (Wednesday) evening, at 8 o'clock, a paper on "The Law in relation to Sanitary Progress," by W. H. Michael, Q.C.

**HUNTERIAN SOCIETY.**—This evening, at 7.30, Annual General Meeting for the Election of Officers.—8. The Hunterian Oration will be delivered by Mr. A. H. Smees.

**ROYAL MICROSCOPICAL SOCIETY.**—This evening, at 8, the Annual Meeting for Election of Officers and Council.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—This afternoon, and on Friday, at 4, Prof. W. K. Parker, "On the Structure of the Skeleton in the Sauropsids."

**DR. THOS. BUZZARD** will lecture at the National Hospital for the Paralyzed and Epileptic, Bloomsbury, on Thursday, Feb. 10, at 5 p.m., on "A Case of Disseminated Sclerosis." Gentlemen who are medical practitioners, or students of medicine, will be admitted upon showing their cards.

**THE CLINICAL SOCIETY OF LONDON.**—Friday, Feb. 11, Dr. Sutherland, "A Case of Chronic Vomiting in which no food, except Koumiss, was taken for sixteen months"—Mr. J. W. Teale (Scarborough), "A Case of Qui-scent Scirrhus"—Mr. Heath, "A Case of Gangrene of the Arm from a Poisoned Wound; Amputation at the Shoulder, and Recovery."—Dr. Whipham, "A Case of small Round-celled Sarcoma of the Dura Mater encroaching on the Left Temporo-Sphenoidal Lobe of the Brain, and producing extensive Softening in its neighbourhood; Absence of Aphasia, the patient being left-handed."

**HARVEIAN SOCIETY OF LONDON.**—Thursday, Feb. 17, at 8.30 p.m., "Cases of Laryngeal Disease," by Dr. Woakes.—"The Treatment of Erysipela," by Dr. Cheadle.

## VACANCIES.

**Ballinrobe Union.**—Medical Officer for the Ballinrobe Dispensary District.—Salary, £100, with £25 additional as Medical Officer of Health. Applications by Feb. 10. (See Advt.)

**Carlow Union, Ballinacorney Dispensary.**—Medical Officer. Salary, £120. Election, Feb. 13.

**Central London Sick Asylum.**—Assistant Medical Officer for the Asylum at Highgate. Salary, £100, with board. Applications to the Clerk at the Infirmary Offices, Upper Holloway, N., by Feb. 11.

**Durham Union.**—Medical Officer for the Guardians District. Salary, £20. Applications to the Clerk of the Guardians before Feb. 18.

**Ventnor Consumption Hospital.**—Resident Medical Officer. Salary, £100, with board. Applications to the Secretary, 12 Pall Mall, London, S.W., by Feb. 14.

## APPOINTMENTS.

**COOPER, J. N., L.K.Q.C.P.I., M.R.C.S.E.**, Medical Superintendent of the Infirmary, St. George's-in-the-East.

**DIWWOODIE, W., M.D., C.M.**, Medical Officer to the Third District of the Bellingham Union.

**EVANS, E., M.B., C.M.**, Public Analyst for the County of Anglesey.

**HAYWARD, R. S., M.D.**, Medical Officer and Public Vaccinator for the Tenth District of the Chelmsford Union.

**LANGTON, J., F.R.C.S.**, Surgeon to St. Bartholomew's Hospital.

**LUCAS, R., M.R.C.S.E.**, Medical Officer for the Fulborn District of the Chesterton Union.

**MAIR, A. F., M.B., C.M.**, Medical Officer to the First District of the Woodstock Union.

**NOARIS, E. S., M.A., M.B.**, Honorary Visiting Surgeon to the Windsor Royal Infirmary.

**OUTLON, H. W., M.D., L.R.C.S.I.**, Resident Surgeon and Apothecary to the Meath Hospital.

**PECK, E. G., B.A., M.R.C.S.E.**, House Surgeon to St. George's Hospital.

**POUND, F. J., M.R.C.S.E.**, House Surgeon to the Royal Hants County Hospital, Winchester.

**ROPER, G., M.D., M.R.C.P.L., M.R.C.S.E.**, Consulting Physician to the Royal Maternity Charity.

## Births.

**BUSHE.**—Jan. 29, at 74 Leeson Street, Dublin, the wife of Cecil J. L. Bushe, M.B., A.M.D., of a son.

## Deaths.

**ASKWITH.**—At Huntley Lodge, Cheltenham, suddenly, Robert Askwith, M.D., aged 65.

**COBBETT.**—Jan. 25, at Petworth, Torquay, Robert Newberry Cobbett, M.R.C.S.E., of Portobello, Edinburgh, aged 50.

**DABBS.**—Jan. 30, at 11 Brunswick Terrace, Buckland, Hants, Fleet-Surgeon George Henry Dabbs, B.N., aged 79.

**DAVIDSON.**—Jan. 31, at Willesden, John Davidson, M.D., C.B., Inspector-General R.N., Hon. Phys. to the Queen, aged 63.

**DONALD.**—Feb. 4, at his residence, 1 Sydney Place, Bath, John Donald, F.R.C.S., Deputy Inspector-General of Hospitals.

**HOLDEN.**—Jan. 27, John Fearnle Holden, Medical Officer of Health for Hull, aged 50.

**LEOD.**—Jan. 29, Freeman Leod, M.R.C.S.E., of Fletcher House, Tottenham, aged 54.

**LUNN.**—Jan. 25, Ernest Craven Lunn, M.R.C.S.E., youngest son of W. J. Lunn, M.D., of Hull, aged 21.

**MORTON.**—Jan. 16, in London, Surgeon-Major Edward Morton, of the Bombay Army.

**PAPINEAU.**—Jan. 28, at Milford House, Hemerton, William Papineau, M.R.C.S.E., aged 62.

**SANSON.**—Feb. 3, at 30 Devonshire Street, London, W., Edith Lillias, daughter of Arthur E. Sanson, M.D., aged 44.

**SCOTT.**—Feb. 3, at East Sheen, Euphemia, widow of John Scott, M.D., F.R.C.S. Ed.

### CERTAIN CONSIDERATIONS REGARDING CHOLERA AND FEVER. (a)

By SURGEON-GENERAL C. A. GORDON, M.D., C.B., Honorary Physician to the Queen.

(Continued from page 110.)

INDIVIDUAL cases from time to time occur in which the symptoms, beginning with hyperpyrexia, gradually merge into such as are adynamic. In former years cases of this nature would have been described as of synocha; more recently, but yet a good many years ago, the expression *typhoid* would have been applied to the latter condition, not, however, in a *specific* sense, but *adjectively*—the counterpart, as it were, of ardent, acute, inflammatory, and so on. Still more recently this term, instead of being applied thus adjectively, as expressive of a *condition*, appears to have a specific significance attached to it, and the resulting turmoil has been considerable. It were well, I think, to indicate clearly in future reports in which of these senses, or in what other, the expression *typhoid*, when applied to a case of fever, is intended to be understood. In some instances the forms of fever (b) met with in India admit of being referred to one or other of the headings in accordance with the official "Nomenclature of Diseases." In the great majority this is only approximately practicable. In China "mixed fevers" are described as such in published reports. In India, cases of fever assigned to climatic causes were, and still are, indicated as "malarial;" this in brief. They are of all degrees of severity; those of greatest violence tending rapidly to arachnoidal effusion and heat-apoplexy—such are, in India, termed heat fever; in China, *pernicious fever*; (c) others, as already remarked, passing into cholera.

(a) Read at a meeting of the Epidemiological Society of London, 2nd February, 1881.

(b) For views of the older medical officers regarding fever generally, see my special reports—I, p. 164, and II., 56-76.

(c) Chinese Customs' Reports, July, September, 1872. Pp. 94-95.

But in reference to a particular type and complication occurring in India, the question is asked by our highest sanitary tribunal, (a) "Is there such a specific fever as enteric fever at all?"

7. *Specific origin theory.*—That certain diseases are due to the action of specific poisons upon the system is a circumstance familiar to, and recognised by, all observers. Syphilis and rabies furnish examples of this class. In both the poison appears to increase in, and pervade the system, but is itself only transmissible, at least, in its acute state by means of inoculation. Other specific poisons multiply and increase similarly, and are transmissible both by inoculation and infection, including contagion. Of this class are small-pox, scarlatina, puerperal fever, &c. (b) That these diseases occur, however, under conditions where neither inoculation nor infection can be traced, or with good reason assumed to have been in operation, is a point forcibly brought to attention by the records of epidemics contained in current medical literature. (c) Certain of these *poisons* are said to be capable of producing now one disease, now another, according to individual conditions and local circumstances insanitary and otherwise; and as a result of recorded experiments, certain animal fluids originally innocuous have, by artificial means, had their characters so transformed as to acquire such properties and their infective principle then called pyrogenic. But, according to my view, analogy justifies the belief that, if by artificial means, transformation or *evolution* of this nature can be induced, equally may it be so by means of the inherent

(a) The Army Sanitary Commission. In the Chinese Customs' Reports, July—September, 1873, p. 56, these remarks occur in reference to dysentery and typhoid fever: "Whether the former disease is always specific is fairly open to doubt, and the specificity of the latter is denied by one of the greatest living authorities on the subject."

(b) Puerperal fever is one of several diseases which arise spontaneously when puerperal women, wounded men, &c., are crowded in hospitals. See Copland's Dictionary, Art. Epidemics.

(c) See "Transactions" of Epid. Society. Vol. iv. Part iii. Among others, Dr. Langstaff (p. 421) indicates that particular groups of disease prevail, some seasonally, others not apparently affected by season. The *diarrhoeal* group has the greatest mortality in the summer quarter, and is most fatal in years with dry hot summers.

vital forces which regulate and determine the general organism of which organic matter is a part.

By analogy also the same or a similar principle applies with regard to various changes which occur in some instances during life, in others after death, and are capable of inducing disease in persons into whose systems matters so altered are introduced. Instances in illustration present themselves in peritonitis, erysipelas, pyæmia, &c. (a); in cadaverous poisoning, in the several affections induced by fish and flesh, meat in various stages or states of decomposition. But on the other hand, we trace many illustrative exceptions. Thus the flesh of animals dead by diseases the most horrible, has been eaten, glanders, for example in a cooked condition, without evil effects; animal poisons have been swallowed without ill effect; black vomit in cases of yellow fever has been swallowed, cholera matters have been tasted and even inoculated into animals and people with similar negative results. Hence I venture to remark the necessity for caution before we assume that because a particular circumstance happens at one particular time and occasion therefore precisely the same circumstance must of necessity occur under all and every combination of conditions. Such an assumption is obviously in disaccord with actualities.

During more than forty years has search been pursued zealously, but vainly, for specific poison of fever or cholera germs. Microphytes, bacteria, vibriones, &c., have each been indicated as the actual cause, each in turn as a result of further observation relieved from such onus. Thus we can only say that cholera as a phenomenon from time to time recurs; that it affects individuals and communities; but in our present state of knowledge, or rather ignorance, of its laws, all circumstances of a positive nature with regard to its prevalence that have been adduced have their counterparts negatively; all of a negative character, their counterparts positively.

Certain forms of fever are assigned to causation of a specific kind. Those to which attention is now necessarily restricted are such as by custom are referred to "malaria," and such as are referred to a specific poison originating in, and propagated by, means of decomposing animal, more especially fæcal, matters. That certain organisms are said to have been detected in the atmosphere of "malarious" places may or may not be a fact capable of standing the test of further minute investigation. (b) Even in the

(a) Dr. Alfred Carpenter believes that the *poison* of typhoid fever may arise *sua sponte*; Dr. King that it may be produced *de novo* by the putrefaction of albuminous stools; Dr. Low that it may arise from a process of "evolution" in decomposing matters; that inasmuch as puerperal septicæmia, pyæmia, erysipelas, or hospital gangrene may develop autogenically under a given combination of circumstances, and then spread by contagion—why not enteric fever? Dr. Cayley, on the other hand, says the weight of evidence is against the *de novo* theory. It has been remarked that "at bottom we are all humoralists and believe in infection; it is not until we have to say where and how that questions arise."

(b) MALARIA.—"At the meeting of the Royal Academy, a memorial was presented, entitled "New Studies on the Nature of Malaria," by Signors Cuboni and Marchiafava. These studies corroborate at every point the conclusions drawn by Professors Klebs and Tommasi-Crudeli as to the vegetable parasite which produces the malaria fever. The young observers have also discovered new facts which may serve to clear up one of the most interesting pathological facts that is, the contagion of infectious diseases. They have been able to communicate the true malaria fever to animals (dogs and rabbits) simply by inoculating them with blood taken from malaria patients, which means that they have rendered contagious a malady which, under natural conditions, can neither be transmitted from man to man, nor from man to animal. They have also found that the presence of the *bacillus malarie*, in its sporadic form, in the blood of malaria patients is a constant fact. This parasite is found in great quantities in the blood during the cold stage of the fever, while in the warm stage it has almost totally disappeared, leaving only traces of its spores. These in their turn can produce a second generation of parasites. In an appendix to the memorial, the authors quote a letter from Dr. Lanzi, of Rome, who declares that he constantly noticed the same fact in the blood of twelve patients in the hospital of San Giovanni, in Laterano, examined by himself during the cold stages of the fever.—There was further presented for insertion in

event of their being so, the presence of such organisms in those localities is itself due to the sum of conditions which induce particular and distinctive phenomena of life in the animal and vegetable kingdoms generally, in those localities, not as apparently as implied, themselves the *cause* of those phenomena. Their own development, judging from published reports on the subject, is not constant; it depends itself upon conditions which only occur at intervals, and on each occasion are temporary in their duration. Certain organisms, bacteria for example, differ even according to the age of materials from which they are produced; sterilised solutions were obtained from new hay, non-sterilised, from old hay. (a) According, so runs the explanation, as to whether they have lost their *inherent generative energy*. (b) Another abstract expression, you will observe.

As to the general disease, fever, I take the definition given recently by one of the highest of living authorities. "It is not only a state but a process; the *state* of fever, once established, it may vary in its course, duration, and local inflammations which accompany it indefinitely." (c) According to views now generally accepted, this state or process may be induced by various causes, some of a nature extraneous to the individual, others inherent in himself.

As far as documents, at my disposal, authorise a conclusion on the subject, the conclusion at which I thus arrive is that with regard to fevers in India, ardent in their characters, attended by cerebral, pulmonic, hepatic, or other complications, except ulceration, involving the glands of the lower part of the small bowel, observers have seen no necessity to *assume* the operation of a *poison*, specific in its nature. But when the later complication does occur in the course of an attack of fever, with or without the presence of low adynamic, that is, *typhus* or *typhoid condition* of the patient, the tendency for some years back has been too much to *assume* the operation of a specific poison, the actual existence of which remains undemonstrated; too little to consider the operation of general conditions as they affect man, individually or in the mass.

The theory of specific poison is thus expressed by its advocates: "enteric fever arises from a specific poison contained in, and transmitted by means of sewer emanations;" also "the poison, the manifestations of which present that group of symptoms called *enteric* fever, and which, in fatal cases, is invariably found associated with lesions in Peyer's patches and mesenteric glands, is as distinct and separate as any of the other animal poisons which produce specific results, such as small-pox, measles, scarlet fever, cholera." But sewer emanations do not always induce such effects in individuals most constantly and directly exposed to them; precisely similar effects also result in cases of fever due to causes other than these. How, then, can specific results arise from different series of causes, the causes themselves non-specific?

Inoculation of rabbits with blood from typhoid fever patients has produced in these animals not specific typhoid fever, but *typhoid septicæmia*, precisely as results from inoculation with organic matter in a state of putrefaction. (d) In this respect there is reason to believe that the *Lepus* manifest a greater degree of susceptibility than

the acts of the Academy a communication by Signor Tommasi-Crudeli. In it the author shows the utility of making experiments on the possibility of rendering the human organism impervious to malaria by small doses of arsenic taken daily. He says he has good hopes that he is well on the road to certainty, and describes the methods he has adopted, but, having instituted a new series of experiments on animals without having been able to obtain a final result, he invites all students to undertake similar experiments, and thus contribute to the solution of so vital a problem." That is to say, a theory is in the first instance elaborated: in the second, facts in support of it have to be sought for.

occurs in man. Unfortunate rodents have been inoculated with hydrophobic saliva from the human subject; death has rapidly followed—but whether or not by hydrophobia, was a point on which the three operators had as many opinions among themselves. (a) So much with regard to a known specific poison.

As further adverse to this theory of specific poison, time alone restricts the number of my references to recognised authorities on the subject; the names of those authorities appear in my printed reports and other documents. Thus the *de novo* origin of fever—in other words, the *evolution*—finds support among the group of observers, names of four among whom are given in my first special report. One writer observes that “fever cannot be traced to any specific poison;” another that “in ninety-nine cases out of every hundred the disease is not from any specific germ;” another that “all medical men are not agreed as to the cause of enteric fever;” another that “causation is so little understood as to give us little help in the diagnosis of this disease;” several others that enteric fever may arise from fatigue and exposure; a still more recent writer that “under special and peculiar conditions enteric fever may become instituted in the system without any external agencies other than such common causes as give rise to that lowered tone of vitality (b) which favours the springing up within itself of the morbid phenomena in question; yet another that “specific causes are not in all cases required to produce an attack of fever—that changes may take place spontaneously in one or more of the functions, and proceed to give rise to the worst forms of fever;” and so on. In India, of the

(a) Dr. Davaine (*Courier Méd.*) remarks that according to the researches of M. Pasteur, we know that putrefaction is the fermentation produced by infusorial animals of the family of Bacteria or Vibrio. The presence of these infusoria is one of the signs which characterise this phenomenon, which, according to Dr. Davaine, may take place as well in a living animal as in the laboratory. But what are putrid diseases? It is in order to reply to this question that the eminent experimenter has made some new experiments, of which the following are a short resume:—

Blood from several patients attacked with gangrene was injected into rabbits without any result. This blood contained neither bacteria nor vibrios. “But if the gangrene,” says Dr. Davaine, “be not itself a septicemic disease, it may become so by putrefaction of the gangrenous parts, and the introduction into the blood of the putrid elements.” This is what took place in an experiment of Dr. Bujale, of which we have spoken.

Dr. Davaine has also made a particular study of typhoid fever. In all the cases the blood of a typhoid patient inoculated on rabbits has caused death in a shorter or longer time, sometimes in a few hours, sometimes after two or more weeks, and he never injected more than the thousandth part of a drop, so that the septic nature of typhoid fever cannot be doubted, “I would add,” said Dr. Davaine in closing his communication, “that in successive generations of poison obtained from the inoculation of rabbits, I have not met with any difference between typhoid septicæmia and that produced by the inoculation of organic matter in a state of putrefaction, either in the phenomena, or progress, or termination of the disease. It is to be noticed, however, that the incubation is generally much longer in the first case than in the second; but in another communication he will show that there is nothing in this special to typhoid fever.

M. Pasteur inoculated two rabbits with saliva from a child just dead from hydrophobia, with the result that both these animals died in less than thirty-six hours afterwards. Their blood, after death, when examined microscopically, presented minute organisms having the appearance of the figure 8; these occurring in masses. These organisms, when introduced into a *bouillon* of veal propagated it rapidly, and when inoculated in other rabbits, induced death similarly as in those from which they had first been taken. But, it is asked, was the disease in either case “la rage?” M. Raynard says yes. MM. Colin and Dejarid-Beaunetz says no. M. Pasteur says neither yes nor no. —*Gazette Médicale de Paris*, 22nd January, 1881.

(b) For example, of 23,000 French prisoners confined at Stettin in 1870-71, 93 were attacked with typhoid fever. The outbreak on that occasion was attributed to the combined effects of hardships, defeat, and imprisonment—that is, to the ordinary causes of typhus in armies under circumstances more or less similar.

Dr. Lowe records the case of a man, dirty in habits, and subject to diarrhoea, becoming ill of typhoid fever in the absence of possible communication with one affected, with water pure, no drains, but his cottage damp, dirty, and overcrowded,

cases investigated by me the reports by medical officers concerned indicate that in no instance among them was an attack of fever actually traced to the operation of a specific poison. Hence, as a general result of what has thus been adduced, I submit that I have good grounds for the opinion arrived at and expressed by me that, not only is the presence of a specific poison undemonstrated in fevers met with in that country, attended by intestinal complications and characterised by a low, typhoid, or adynamic condition of body, but that such cases of fever occur as the results of general conditions, climatic, endemic, epidemic, and others, acting upon particular conditions and diatheses of individuals.

This view, I submit, finds support, by analogy, in recent published reports of diphtheria and scarlatina in this country. (a)

Certain diseases which undoubtedly in the first instance have arisen without the intervention of a specific poison or poisons, have subsequently spread by means of specific contagion. Typhus fever in camps, dysentery in fleets, ophthalmia in barracks, pyæmia in war hospitals, are examples in point. (b) But sudden outbreaks at places far apart, of diseases such as we are now considering, seem to me to indicate that they also, although capable of becoming epidemic, and in particular instances of being propagated by contagion, yet, as in the instances before us, their first development occurs autochthonously and autogeneously. In India, cases of fever occur that no theory of specific contagion can explain. (c) The doctrine of specific poison is altogether inapplicable to the history of what is called enteric fever in that country. (d) So say high authorities on these subjects.

(a) See *Brit. Med. Journal*, 18th Dec. 1880, p. 989:—

“DIPHTHERIA AT THE CHILDREN'S HOSPITAL.—A very remarkable, though unfortunately completely negative, report has been made by Mr. W. H. Power, into the circumstances attending the outbreak of diphtheria in the Great Ormond Street Hospital for Sick Children in March of this year. The outbreak in question was without parallel in the history of the hospital. . . . In-patients of four out of the five general wards of the hospital were almost simultaneously attacked by diphtheria or scarlatina, and this under circumstances that seemed to exclude, at least in the majority of cases, antecedent human infection. Mr. Power's inquiry, though thorough and searching, has not succeeded in demonstrating a cause of the diphtheria. . . . The five initiatory cases of throat-illness in the several wards invaded had all been resident in the hospital for thirteen days and upwards before attack; all of them but one for nineteen days or more before they fell sick—a circumstance that seems to indicate that the children did not themselves introduce infectious disease to their several wards. . . . In Louisa Ward scarlatina was followed, after intervals varying from twelve to eighteen days, by scarlatina, measles, and diphtheria. In Alexander Ward diphtheria was, within three days, followed by cases of scarlatina and by acute albuminuria. In Alice Ward diphtheria was quickly followed by diphtheria and sore throat, and whooping-cough; and after an interval of nearly three weeks, by an additional case of diphtheria. . . . Thus, Mr. Power finds it necessary to close his report without having arrived at any definite answer to the question how diphtheria was produced in the hospital—a disappointing, but apparently inevitable, result.

(b) Dr. Low describes a case in which typhoid fever, originating from bad hygienic conditions, was itself propagated by infection. He thinks that under *progressive* development *infectiveness* may become elaborated from a succession of attacks of diarrhoea.

(c) Surgeon-Major Don.

(d) Cunningham. See Macnamara p. 90:—

“As an example of the lengths to which the followers of the specific poison theory have to go in their search for explanation, according to that theory, for the cause of ‘enteric or typhoid’ fever, the following extract from a letter which recently appeared in a medical journal sufficiently indicates, namely:—‘From time to time I have had cases of typhoid fever under my care when the local dispositions were anything but favourable for such, nor was I able to trace their origin to a typhoid source. What struck me as rather remarkable in connection with these cases was their occurring in houses where persons who were much about them prior to and during their illness had leucorrhœal discharges, and none of which persons got the typhoid. The idea has occurred to me frequently (and no work that I have looked into on the subject alludes to it as an origin of the disease) that perhaps the matter which produces typhoid fever may be or reside in some special kind of uterine or vaginal secretion.’”

## CLINICAL LECTURES

ON

INFANTILE PARALYSIS, AND ACUTE ANTERIOR  
POLIO-MYELITIS IN ADULTS. (a)

By THOMAS BUZZARD, M.D., F.R.C.P.,

## LECTURE II.

(Corrected from a Shorthand Report.)

SOME thirty or forty years ago Dr. Marshall Hall adopted the term "cerebral paralysis" for cases in which a lesion had severed the cerebral influences from the paralysed limbs; and the term "spinal paralysis" for the condition in which the spinal influence was cut off from the paralysed limbs.

I may very roughly illustrate the two divisions in this way

Let A represent the intra-cranial centres, with a portion of spinal cord below; B a trophic centre at any part of the cord; C a spinal nerve branching and distributed to muscle. Now a lesion occurring anywhere above B would produce "cerebral paralysis," whether it occurred in the intra-cranial cavity or below it, *i.e.*, so long as it only cut off the influence of the cerebrum; whilst "spinal paralysis" would be, when there was a lesion at B or the nerve below it, cutting off the influence of the spinal cord. As we saw in our last lecture, the seat of the spinal influence is in the anterior horn of the grey matter. A lesion, then, at that point would produce what is called "spinal paralysis." So also would a lesion in the trunk of the nerve, and in the intra-muscular branches.

The difference between these two forms of paralysis is this. In the first case, although paralysis is produced, there is, practically, no impairment of muscular nutrition or alteration of faradaic excitability.

In spinal paralysis, on the other hand, besides the loss of power, there is impairment of muscular nutrition, and either complete absence or great reduction of faradaic excitability.

This patient, S. —, *æt.* 39 (a case of ordinary left hemiplegia), is an example of cerebral paralysis. He has but very small power of using his left arm. The other man, W. —, *æt.* 45 (a case of acute anterior polio-myelitis affecting both arms), a patient whom Drs. Jackson and Ferrier have kindly permitted me to show you, is an example of spinal paralysis. His illness began suddenly twenty-nine weeks ago. One morning he was unable to raise weights; during the day he became worse, and by the evening he could not put either hand to the top of his head, and a little later had entirely lost power in the hands. On admission he could only just flex his fingers, and had scarcely any movement at all in his arms. None of the muscles responded to faradism, but they contracted to the slow interruptions of a constant current. At the

present time all the muscles react to faradism except the deltoids.

I propose to show you very briefly the different electrical conditions of the deltoid muscle in the two patients.

I have a battery here which enables me to use either induced or constant currents, and I apply one of the rheophores at the back of the neck, the other to the deltoid muscle of the hemiplegic patient. First, I put on an induced (faradaic) current, and the deltoid muscle, as you see, contracts very freely. When the same strength of current is applied to the patient W. (the case of spinal paralysis), you observe that there is no contraction of the deltoid muscle. I now apply a stronger and stronger current, and there is still no response in the deltoid muscle. Do not mistake a little contraction which you see in the neighbourhood. It is in the pectoralis major. One rheophore being at the nape of the neck, any muscular fibres which lie in the direct line between that rheophore and the other will necessarily get stimulated, and will contract if they are capable of being excited by faradaic currents. The strongest induced current, as you see, produces no effect upon the deltoid muscle.

I will now employ the constant current (galvanic or voltaic current), and first of all apply it to the patient with left hemiplegia—the case of "cerebral paralysis"—one rheophore being fastened to the back of the neck, and the other, representing the kathode or negative pole, on the deltoid muscle. I suddenly complete the circuit—you see there is a contraction. The current was derived from 28 cells.

Let me here remind you that when the constant current is flowing evenly in circuit through the body, there may be a very considerable power of current, and yet no muscular contraction will occur. It is when the circuit is suddenly opened or suddenly shut that you get a contraction; and we are indebted to Brenner for the formula which shows the order in which contractions naturally occur in these circumstances.

The positive pole is called the anode (from *ἀνα ὄδου*, "the way up"), and the negative pole is called kathode (from *κατα ὄδου*, "the way down").

Now if we imagine this (a diagram was here drawn) to be the carbon and this the zinc, the current is supposed to flow up from the carbon or positive pole, and down to the zinc or negative pole. So it is usual to employ the term "anode" for the positive pole, and "kathode" for the negative pole, of a voltaic battery.

To express a sudden closure of the circuit, the term "Schlieszung" (S) is employed by the Germans; "Oeffnung" (O) for opening; "Zuckung" (Z) for contraction. By means, therefore, of these initial letters we can very shortly picture all we desire to record.

With a galvanic current of moderate strength, supposing the kathode be placed upon the muscle, and the circuit suddenly completed, you get a contraction—a small contraction, and that is written down thus, K S z (using a small capital z).

I use the German plan because it is convenient that observers of different nationalities should be able to read each other's records without the necessity of translation. The circuit being opened (K O) there is no contraction. In health the contraction (K S z) is the only one which occurs when a moderate current is employed. When you use a stronger current you get a powerful contraction portrayed by a large Z, *i.e.*, K S Z. But besides this you now get a moderate contraction on anodal shutting, and a moderate contraction on anodal opening (A S z, A O z). That is the normal condition.

We will now turn to this case of polio-myelitis, and you see a very remarkable change.

First of all I will show you that that muscle which did not respond to the strongest induced currents, does respond to slow interruptions of a constant current. When the negative pole is placed on the deltoid, and the circuit shut, there is a contraction. That illustrates what is called the "reaction of degeneration." I am using nineteen cells of Coxe's battery. This is "katho-

(a) Delivered at the National Hospital for the Paralysed and Deaf.

dal shutting," there is a contraction, but not a very large one. (K S Z).

"Kathodal opening :"—there is no contraction. (K O—)

"Anodal shutting :"—there is a larger contraction than in kathodal shutting. (A S Z)

"Anodal opening :"—there is no contraction. (A O—)

So that, you see, if we want to record the condition of the muscle we write it down in this way :—Faradaism O ; Galvanism A S Z > K S Z, i.e., the contraction on closing the circuit with the anode on the muscle is greater than that which occurs on closure of the circuit with the kathode on the muscle.

This qualitative change is one of the peculiarities of the reaction of degeneration. The test will, I believe, acquire greater importance as we learn to understand better its prognostic significance, of which I cannot say much at present. The process is useful for the purpose of testing and recording very slight changes in muscles where you think there is some degeneration.

Let me call your attention to another point of very considerable interest. This patient, W—, can move his deloid to a certain very evident extent by voluntary action.

Duchenne pointed out that after traumatic lesion of a nerve causing loss of faradaic excitability in muscles and the other signs of degenerative reaction, the power of responding to volitional impulses has returned long before faradaic excitability. Erb, Bernhardt, and myself have recorded a similar condition in regard to lead palsy (*Brain*, No. 1). I have seen, in a case of lead palsy, marked loss of faradaic excitability in muscles belonging to a limb said by a patient to be perfectly well.

I lately saw a case of infantile paralysis in a little boy, five weeks after the attack. His legs were completely paralysed. His arms had been slightly affected, I was told, but had quite recovered. He used them freely in my presence. Yet I could get no sign of faradaic excitability in them, even when I used very strong induced currents—indeed, far stronger than would be required in health.

I have another case of polio-myelitis in a grown-up patient in the hospital.

The person is a young woman sixteen years of age ; but as I shall have to show her next Thursday as illustrating another matter I do not propose to present her to you here to-day.

She was attacked twelve months ago with loss of power in both legs. Four months after this she was admitted here.

At that time there was in the right leg no response in the peroneus longus to the strongest induced current.

The anterior tibial group of muscles responded to strong currents. In the right quadriceps extensor there was no response to either current. But at the present time—and that is the point—that muscle reacts to about twenty cells of constant current, slowly interrupted, in the way I have shown.

#### DIAGNOSIS.

As regards the diagnosis this is not difficult. An extremely rapid loss of power in limbs after a febrile attack hardly admits of much error, especially if the electrical testing shows that the faradaic excitability of the muscles is absent or notably lowered within a week after the attack. In polio-myelitis affecting the upper extremities it is necessary to bear in mind that hypertrophic cervical pachymeningitis will cause paralysis with wasting of a kind which recalls a good deal the character of that occurring in polio-myelitis. But in pachy-meningitis the course is slow, often occupying weeks during which the condition gets progressively worse, and in addition to this, owing to the membrane being inflamed in its whole circumference, and posterior roots as well as anterior being thereby involved, strongly marked symptoms will occur on the sensory side. There are pains of extreme severity darting through the limbs, and there is more or less cutaneous anæsthesia. An injury to a mixed nerve will produce paralysis with wasting, and the nerve and muscle when tested will show the reaction of degeneration just as occurs in polio-myelitis ;

but the anatomical distribution of the lesion which will be found exactly limited to the district of the nerve, and the affection of cutaneous sensibility will serve to distinguish. It is much more difficult to differentiate localised lesions of anterior roots of nerves, for the nearer you get to the centre the more apparently irregular becomes the distribution of resulting lesions. The mode of onset and the circumstances will, however, probably indicate whether there is any probability of lesion confined to the anterior roots. One can imagine a tumour pressing upon the anterior surface of the cord and involving the anterior roots, a gumma, for example, causing symptoms indistinguishable from those of myelitis of the anterior cornua.

There is one possible source of error which, so far as I am aware, I am the first to point out. As the affection we are considering is peculiarly apt to attack very young children, it will be useful if I relate an incident which occurred to myself. I saw a year or two ago a female infant, one year old, who was described as having rather suddenly lost the use of the right lower extremity after a few hours' malaise with some little febrile disturbance. The story told was, in fact, exactly the story of infantile paralysis. When she was stripped she appeared a well-nourished, healthy-looking child. She did not move the right lower limb, but looked at it as if in some distress, and appeared to guard it with her hand. I examined it first to ascertain if there were any signs of injury, but found none. It was evident that pressure was painful, but nothing could be found in the limb to account for this symptom. The powerlessness was in striking contrast to the free movements of the left leg.

Now, the occurrence of tenderness, although unusual in infantile paralysis, was not of itself sufficient to remove the case from the category of that disease. It was marked, for example, in the history of a case brought by Dr. F. Taylor before the Pathological Society last year. Investigation of the child's general health threw light upon the case. The urine was found to deposit a very large quantity of uric acid, and the explanation of this appeared to be that it was being nourished upon a milk food which contained an enormous amount of sugar. A few doses of citrate of potash and a purgative, completely cured the child who, in a day or two, was as strong as ever on this limb. What happens in such a case I believe to be this. Minute crystals of uric acid get deposited in the loose connective tissue which intervenes between large muscles, and enables them to glide over each other, especially at the back of the thigh and in the loins. These collections of connective tissue have been shown to be lymphatic spaces, and in these the uric acid sets up some subacute inflammation which not only causes pain and tenderness, but renders the muscles almost powerless for the time being. Such a cause, I think there can be little doubt, frequently obtains in those cases of lumbago, and so called sciatica, which are rapidly cured by free purging and alkalies with iodide of potassium. I am indebted to Dr. Burdon-Sanderson for originally suggesting this point to me for observation.

(To be continued.)

#### REMARKS ON A CASE OF FIBRO-MYXOMA. (a)

By WILLIAM THORNLEY STOKER,

Fellow, Member of Council, and Professor of Anatomy, Royal College of Surgeons, Ireland ; Surgeon to the Richmond Hospital, and to Swift's Hospital for Lunatics.

AMONG the tumours which frequent the tissue of the uterus, and which have so much interest at a time when the surgery of that organ is yearly, I might almost say, daily, undergoing such transition and advance, the most common is that which has been called a "fibroid" by Rokitsansky, or a "fibro-myxoma" by Virchow, and which is so usual that Bayle stated that 20 per cent. of all women dying after the age of 35 are affected by it ; while

(a) Read before the Surgical Society of Ireland.

Klob has more recently informed us, that uterine fibroids may be found present in 40 per cent. of women who die after 50 years of age. The interest and frequency of the disease are my reasons for offering to the Society a very beautiful example of a uterus so affected, together with a few details, unfortunately, mostly culled during a post-mortem examination, which bear on points of diagnosis or treatment.

Concerning the structure of these fibro-myxomata the latest pathology expresses little doubt or difference of opinion. To say that they are composed of fibres of involuntary muscle, resembling those of the uterus itself, mixed with true fibrous tissue, in varying proportions, is to epitomise our knowledge of their structure. Virchow has sanctioned their arrangement into two classes, the "hard," and "soft," myxomata, the fibrous element preponderating in the hard, and the muscular in the soft variety. This view is compatible with the different ideas that existed as to their nature, and reconciles various opinions, by the simple explanation that the appearance and characters of the tumours may vary in endless degree in correspondence with their varying proportions of muscle, or fibrous material.

On the 12th of last October, I admitted into the Richmond Hospital a woman, named Catherine T., a French polisher by trade, unmarried, and 34 years of age. She was a sallow, wiry, thin person, but not emaciated, and excepting her uterine trouble, described herself as having had good health, and having been able to follow her occupation up to a week or so previous to presenting herself for treatment.

She said that she had noticed her abdomen becoming larger for the last two years, during which time she suffered from dysmenorrhœa, but had not undergone any considerable inconvenience until about two months before her admission into hospital. During this latter period, she had noticed her abdomen growing rapidly in size, and had suffered pain, as well as trouble from interference with the acts of urination and defæcation.

A manual examination of the belly discovered a large hard tumour occupying the centre and left side of that cavity, and extending as high as three inches above the umbilicus. It was exceedingly irregular, both in surface and outline, and had much the character to the touch of an enormous knobby Jerusalem artichoke. Over that portion of its surface occupying the umbilical and lower part of the epigastric regions, a distinct fluctuation showed the presence of fluid. This condition, simulating a large cyst, showed its true nature by its disappearance when a catheter was passed into the bladder and a large quantity of urine drawn off.

A digital examination of the vagina revealed the occupation of the pelvis by the lower end of the mass, presenting here like a fetal head, lying on the perinæum and filling the hollow of the sacrum. The vagina was so occluded that the os uteri, which was pulled upwards by the abdominal extension of the tumour could not be reached by the finger, and consequently, the sound could not be employed.

It was noticeable that while the tumour in the abdomen rotated smoothly to a small extent, when pressed alternately on either side, that portion occupying the pelvis was perfectly immovable by any degree or direction of pressure that could be employed during an examination without anaesthetics. This condition, which was somewhat puzzling during life, and gave rise to fear that firm attachments to the pelvic bones existed, was easily explained after death by finding that the upper and lower portions of the growth were distinct tumours, and easily moveable the one on the other.

It was evident that I had to deal with a large uterine tumour probably of the ordinary fibro-myxomatous type, and as a necessary preliminary to entering on the question of a hysterectomy for its removal, I determined, in consultation with my colleagues, to endeavour—having produced anæsthesia—to push above the brim that portion of the disease which occupied the true pelvis. This was neces-

sary, not merely for the palliative purpose of freeing, if possible, the outlets of the bladder and bowel, but also as a means of discovering whether such pelvic attachments existed as the extreme fixity of the lower part of the tumour rendered probable, and which, if present, would forbid any attempt at the radical operation of removal through an abdominal incision.

Pending this attempt the patient was kept quiet in bed, a catheter passed when necessary, and a little irritability of the stomach which had shown itself combatted by proper treatment.

Six days after her admission she was seized in the evening by a fit which lasted nearly half an-hour. It was looked upon by the resident pupil in charge of the case as hysterical, and not recurring, attracted no further attention. It proved, however, when the kidneys came to be examined after death, to have probably had a grave significance, and it is likely the attack was of renal origin. Four days afterwards when, during the evening she had gone a little distance along the ward, she suddenly got weak, and was helped back to bed only in time to die there quietly of syncope.

A post-mortem examination revealed disease not only in the uterus but in the heart and kidneys. The condition of the kidneys was one of deep interest, not merely on account of its probable connection with the state of the heart, from which organ the immediate cause of death proceeded, but also in relation to the question as to how far the retention of urine caused by the pressure of the tumour had been the starting point of the renal complication.

Both the kidneys were in a state of chronic parenchymatous inflammation, more advanced in that of the left side, in which several small abscesses existed.

The heart presented that form of hypertrophy of the left side usually found in chronic renal disease. On opening the right cavities a large clot, evidently antemortem in its formation, was found passing from one to the other through the tricuspid opening. The venous system was enormously gorged with blood, and it was clear that the proximate cause of the syncope which produced death was the failure of the heart's action consequent upon the patent condition of the tricuspid opening, due to the large clot which passed through it.

The bladder had been so forced up that its cavity lay entirely above the line dividing the hypogastric and umbilical region, and its neck and the urethra were pulled out and elongated so as to form a sort of stalk which passed down into the pelvis.

The ovaries were quite healthy. The womb, which I exhibit to the Society, has now shrunk greatly from having been some months in spirit, but its former size may be judged, when I say that it extended from the perinæum to three inches above the umbilicus, occupying the centre and left side of the abdomen. Its outline is exceedingly nodulated and irregular, and a section of it shows that its substance is occupied by a large number of tumours which the microscope has proved to be of the fibro-myxomatous type. They are mainly spheroidal in form; when any departure from this shape is present, it is due to the development of secondary tumours in relation to the surface of pre-existing ones. They vary in size from a pea to a mass forming one half of the entire growth, and two of them, which form nearly the entire tumour, grew respectively in the anterior and posterior walls of the womb; the former, which extended upwards and forwards, constituted the abdominal portion of the tumour, and the latter growing downwards and backwards is that which occupied the pelvis. Between the two is a deep sulcus in which the promontory of the sacrum fitted.

On examining them carefully it will be seen that all the smaller and younger tumours were imbedded in the substance of the uterus, are, in point of fact, intra-mural, while only those of larger growth and greater age have pushed their way outwards, so as to become sub-peritoneal. Every intermediate stage between a completely

intra-mural condition and an entirely sub-peritoneal one, may be found. None of them have passed inwards towards the cavity of the womb, so as to assume the sub-mucous condition. The cavity of the womb has been elongated, so that it measures six or seven inches in length, and has been so deflected over the convex upper surface of the pelvic tumour, that its axis, much contorted, runs first upwards and backwards, and then downwards, and to the left side.

I have not given the weight of the tumour, because I do not believe in these cases that it is any criterion as to size, some small tumours being comparatively heavy, while others of large bulk weigh but little, owing to their lesser density.

It was formerly common to describe these tumours as being encapsuled, the mistake arising from the appearance of circumferential lamination, due to the squeezing together by the enlarging tumour of the surrounding muscular tissue of the uterus. The microscope has shown that this so-called capsule is the altered uterine substance, and in further evidence of this, we have the facts that it disappears from the surface of such tumours as have become sub-peritoneal, leaving them covered on their abdominal aspect by peritoneum alone; and that it only assumes the character of a capsule, from which the tumour can be "shelled" out, when the growth has existed for long enough to destroy a degree of its vitality by pressure, and when the vascular connection has lessened with ceasing growth. If it were a true capsule it would develop with the tumour, and the larger the tumour, and the more advanced its development, the more intimate would be the connection between it and its capsule.

I think the specimen is of great interest as illustrating the following points:—It gives excellent examples of an important uterine disease. It shows tumours in different stages of growth, and in different parts of the uterus, illustrating the fact that they are usually found in the anterior and posterior walls, and do not appear in the cervix, probably owing to its more fibrous structure. It shows the way in which, according to the highest authorities, these myomata having first commenced in the substance of the uterus, and imbedded in its walls, finally pass in their process of growth, either towards the peritoneum, or inwards to the cavity of the womb; or, in other words, assume only as a secondary condition, the sub-peritoneal or sub-mucous situation. A close examination of the specimen will also show that the fibroids in this uterus are not only multiple in the sense of there being a number of them situated in different parts of the uterine walls, but that each of them is what is termed an "agglomerated fibroid," that is to say, is composed of a multitude of different nodules, all enclosed within one common boundary, but each carrying on its own individual growth.

In addition to the interest of this case in affording so good an example of an important uterine disease, several points of a clinical nature seem to receive some elucidation or emphasis from the facts I have detailed. They are—

- 1st. The mobility of a portion, only, of the disease.
- 2nd. The impossibility of introducing a sound, even if the os could have been determined.
- 3rd. The condition of the bladder.
- 4th. The probable cause of the renal disorder; and
- 5th. The light thrown by the case on the degree and direction of any pressure that might have been employed to place the tumour above the brim.

With regard to the first—the condition of absolute fixity of the lower part of the growth, owing to the way in which it was wedged in the pelvis, while the abdominal portion revolved with some freedom—I need not remind those who are in the habit of handling uterine and ovarian tumours for diagnostic purposes, that it is useful to put every variation such as this on record for future guidance.

The difficulty of determining whether a tumour is of the uterus or of the ovary, or of both, is often so great,

and is so much assisted by palpation that a circumstance like this, which might confuse or mislead the intelligence of the fingers, may well be mentioned. Here the upper part moved so readily, as ovarian rather than uterine out-growths are prone to do, and the pelvic portion was so unmistakably not ovarian, that the error might have been made of thinking that disease of both organs was present, more particularly as the blocking of the pelvis made the use of the sound impossible. An examination of the specimen will show, even though contracted and hardened by the spirit in which it has been preserved, how freely movable on each other the upper and lower portions of the tumour are—a condition due to their existence in the anterior and posterior walls of the uterus respectively; the intervention of the cavity of the womb permitting their independent movement.

As to the second point I have mentioned, the flexion of the cavity of the uterus was so extreme that the sound could not possibly have been introduced beyond a very short distance, even if the os could have been determined, and being checked, would, of course, have thrown doubt on the enlargement of the cavity, although, as you have seen, it was extreme.

Concerning the state of the bladder, it will be remembered that the fluctuating area which it produced over the upper part of the tumour, was confined to the umbilical and epigastric regions, and, contrary to what might be expected, did not exist in the hypogastric region immediately above the pelvis. This condition is worthy of note as being an exception to what is usually found in such cases, and as being likely to mislead, and be confounded with a cystic portion of the tumour. Generally the tumour formed by the distended bladder of obstruction has its fluid character well evidenced above the edge of the pubis, while in this case the fluctuation did not approach the pelvis, owing to the attenuated stalk or pedicle formed by the stretching of the urethra and neck of the organ.

I consider the disease of the kidneys, as of extreme interest. The disorder which here existed (chronic parenchymatous nephritis) is one that is, admittedly, sometimes produced by urinary obstructions, and I see no reason for doubting that in this instance the pressure on the urethra was the primary cause of mischief. I am borne out in this idea by learning from Dr. Kidd that he believes the same train of events to have occurred in a person under his care, and suffering from the same affection of the womb as my patient. According to this theory the sequence probably was—

- 1st. Uterine tumour; 2nd. Obstruction of urethra;
- 3rd. Nephritis consequent thereon; 4th. The hypertrophy and thrombosis of heart usually associated with kidney disease, and which caused the sudden death.

The bearing of this case on the relief of uterine out-growths, by pushing them above the true pelvis when they have got hitched or fixed below its brim, and are producing evil effects by pressure, should interest the members of the Surgical Society particularly, because, although an Irish provincial surgeon had previously proposed by mechanical means to push up above the brim a pregnant and retroverted uterus, and thus avert a formidable danger, it is to Dr. Kidd that we owe the suggestion and the practice of making this attempt in cases of enlargement from disease. I need not recapitulate here the many evils besides the obstruction of the urethra or bladder which a uterine tumour growing into the pelvis may by its presence produce. Among them is one mentioned by Dr. Browne, of Baltimore, in the *American Journal of Obstetrics for 1877*, which, no less than the state of the kidneys, may, in this case, account for the eclampsia, as he describes an instance where such convulsions were produced by the pressure of the tumour. Inasmuch as it generally grows downwards and backwards, the first proceeding of a uterine fibroid is usually to fill the recto-uterine space, and to exercise its earliest ill effects on the bowels. From its probable extension in this direction it is likely to get hitched below the promontory of the sacrum, and to necessitate any pres-

sure used to push it upwards being exercised in a direction sufficiently forwards to clear that prominence.

It is in connection with the line of pressure to be used and in relation to the apparent fixity which the overhanging sacrum may give to the tumour, that I would deduce a lesson from my patient's case. In the first place the relation of the sacral promontory to the tumour was such (owing to the way in which the disease extended downwards and backwards) that no amount of force would have sufficed to move it upwards unless applied with an inclination forwards much exceeding that of the axis of the brim; and, in the next place, such a degree of force—as the post-mortem showed—should, and could successfully have been used, as might beforehand have been deemed unsafe and unnecessary.

As regards the means of pressure to be employed, I take it that no royal rule can be laid down. Whether by the hand in the vagina or in the rectum, and whether in the former case assisted, as Dr. Kidd has proposed, by Barnes's bag in the rectum, must be left to the discretion of the operator and the individual requirements of the case. Of this I am sure—that in the instance I have recorded the pressure of the bag would have been of little assistance, and that nothing short of the power afforded by the use of the whole hand as a means of pressure would have availed.

## Clinical Records.

### CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

*A Typical Case of Mitral Constriction following Scarlet Fever.*

Under the Care of Dr. EUSTACE SMITH.

Reported by SIDNEY DAVIES, B.A., late Clinical Assistant.

AMELIA H., *æt.* 16, was admitted into the City of London Hospital for Diseases of the Chest, on Nov. 8th, 1880. The patient was a small, ill-developed girl, 4ft. 9in. in height, and 5 st. in weight. Her occupation consisted in assisting her mother to clean offices, &c.

She had enjoyed good health until fifteen months before admission, when she had an attack of scarlet fever, with which she was confined to bed for four or five weeks. After recovery she related that she had suffered from cyanosis, dyspnoea, and a pain, not very severe, in the left side. These symptoms compelled her to relinquish her occupation, which she had resumed immediately after recovery from the scarlet fever. She sought relief at the hospital as an out-patient, and was recommended for admission. She had had a slight cough, and there had been some loss of flesh. When questioned on the subject she stated she had occasionally suffered from dyspnoea before the scarlet fever. Her family history was good, father, mother, and four brothers and sisters being alive and in good health.

On admission she appeared wasted and anæmic. The tongue was clean and pale; bowels regular. She had a slight cough, but no expectoration. She had a small 'running' pulse, beating 120 per minute; temperature normal; the urine was clear, acid, specific gravity 1020, and contains no albumen. The catamenia had not commenced. Dr. Eustace Smith made a physical examination of the chest shortly after admission, with the following result:—

Heart's apex one inch below the nipple, and in the nipple line. On palpation a very strong præ-systolic thrill is felt there; the thrill is also felt when the hand is laid flat on the chest over the præcordial region. There is a faint impulse at the left side of the ensiform cartilage, accompanied by the same præ-systolic thrill. The upper margin of the heart's dulness reaches the second rib, and the outer margin extends a third of an inch to the right side of the sternum. On auscultation double pericardiac friction is heard at the base of the heart. A loud, low-pitched præ-systolic murmur is heard all over the præcordial region; this murmur ends abruptly with a sharp sound resembling the second cardiac sound, though it is in reality systolic. The second sound is heard more faintly at the beginning of the murmur. The point of greatest intensity of the murmur is midway between the ensiform cartilage of the nipple line. It is heard to the left as far as the posterior axillary line. Pulse very small,

regular in rhythm, much swollen, and at times hardly perceptible when the hand is held above the head. No rhonchus at the bases of the lungs.

The patient was treated with haustus ferri alkalinus, ter die, under the influence of which, aided by the rest gained in the hospital, she rapidly improved, gained six pounds in weight in four weeks, and went out the day after Christmas Day in an apparently robust condition, though the physical signs were little changed.

## Special.

### ARMY, NAVY, AND INDIAN MEDICAL ITEMS.

**MEDICAL DEPARTMENT OF INDIA.**—In the House of Commons, last week, the Marquis of Hartington, answering questions put to him by Sir G. Balfour and Mr. Pugh, said he hoped shortly to lay on the table of the House papers relating to the recent modification in the medical staff of India, which he hoped would prove satisfactory to the Service.

**INDIAN MEDICAL SERVICE.**—We understand that a revised scale of pensions for the Indian Medical Service is now under consideration of the Secretary of State, and that it has been decided, should the new scale be adopted, to make its provisions applicable in all cases of retirement subsequent to Jan. 1, 1881.

**THE NON-RECOGNITION OF ARMY MEDICAL SERVICES.**—How comes it that in some despatches recently published and having reference to a particular division of troops on the borders of Afghanistan, while every other branch of the military services obtain "honourable mention," not one word appears about the medical or any of its officers? If the omission is accidental, the sooner it is rectified the better. Doctors, like other people, like to see their good work recognised by the authorities, and very naturally consider themselves aggrieved when it is not.

**VACCINATION IN BENGAL.**—It is stated that the extravagant belief and prejudices with which the people of Bengal are inspired by those whom superstition or self-interest may induce to mislead them, continue to influence the natives in many parts of the province, and, as a result, inoculators are still at work producing small-pox, and hindering its prevention to the utmost. It is evident that among them the advantages of vaccination have yet to be appreciated as they deserve to be. But perhaps the natives of Bengal are not altogether singular in this respect.

**THE RELATIVE ENDURANCE OF INDIAN TROOPS.**—During the late military operations in Afghanistan, the native Madras troops occupying the Khyber Pass were more healthy than were their comrades of the Bengal Army Service along side them; and, moreover, enjoyed better health than they usually do in cantonments in their own country. The unusual state of health on that occasion is attributed to the circumstances that they drew rations from Government, and having no means of parting with a portion of them, either to their families, as in Madras, or by sale, as in Burmah, had only the alternative left of consuming them; also that they were better clothed than they are in their own Presidency. All Madras troops are eaters of meat, most of the Hindostanees are not; among the former ardent spirits are by no means eschewed, as they are among the stricter Hindoos of the Northern Presidency.

**SURGEON D. H. CULLIMORE**, Indian Medical Department, formerly Residency Surgeon, Mandalay, has retired from the service, receiving the half-pay pension of his rank and length of service.

In the Army Estimates just issued the vote for medical establishments and services shows a decrease of £7,900. It is explained that the "decrease is chiefly due to the retirement of a large number of officers in receipt of the *maximum* rates of pay, and to the charge for Civil practitioners being reduced, in consequence of the Medical Department having nearly arrived at its normal establishment." At the War Office, a Deputy-Surgeon-General, at a salary of £900 a-year, has been reduced in the Medical Division.

As the time draws nearer when the changes in the higher appointments of the public services are to take place, speculation is active with regard to that of Director-General of the Army Medical Department. Various names are mentioned in

connection with that appointment, and surmises are not wanting that the present incumbent may obtain a still further extension of his office.

THE *United Service Gazette* states that the new constitution of the Army Medical Department has been frankly accepted by all, that a praiseworthy *esprit de corps* has been engendered, and that nothing has helped more in this than entrusting medical officers with the discipline of their men. We are glad to be so informed. At the same time we must express our belief that the professional care of men while in health, and their treatment when sick or wounded, were more particularly the duties of the medical officer than inflicting punishment, seeing to entries in defaulters' sheets, checking lists of clothing, and so on—all of which come within the sphere of captains and subalterns.

## Transactions of Societies.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 11.

The President, JOSEPH LISTER, D.C.L., LL.D., F.R.S., in the chair.

Dr. H. SUTHERLAND on

A CASE OF CHRONIC VOMITING, IN WHICH NO FOOD WAS TAKEN, EXCEPT KOUMISS, FOR SIXTEEN MONTHS.

The patient, a girl, *æt.* 24, on admission, had been for five years under his care at St. George's, Hanover Square Dispensary. One year and seven months ago the vomiting commenced; the attack coming on at first only once a fortnight, but lately it has occurred always once, and sometimes five or six times a day. As far as could be ascertained, there was no organic disease of the stomach, no tenderness on pressure, or cachexia, nor any other constitutional symptoms. Every known remedy was tried to allay the vomiting; bismuth, opium, hydrocyanic acid, creosote, carbolic acid, hyposulphites, &c., without any satisfactory result. All attempts to cure the case by dieting had failed, and the patient could keep nothing on the stomach as food, except koumiss, which she had taken for sixteen months. She is, however, able to retain a quinine and orange mixture, and also sherry in small quantities, for brandy makes her sick immediately. The uterus was not displaced. The object in bringing the case before the Society, was to ask if any member could suggest any remedies or mode of treatment in this distressing case.

The PRESIDENT remarked that it was interesting to know that koumiss could be retained by a stomach which refused all other food.

Dr. JAGIELSKI said his experience of koumiss was favourable to it as a food, when other substances fail. He considered the special value of the material to be in its permitting recovery of the digestive organs to take place during its use; and the subsequent resort to other diet when this has occurred. The literature of koumiss had much increased in the last fifteen years, but he considered Dr. Sutherland's a unique case, inasmuch as the patient seemed actually to have progressed. He thought it would be interesting to arrive at an accurate diagnosis respecting it, as an aid to future treatment. In those cases where disinclination to food, and especially to milk, existed, koumiss was an admirable substitute. In its preparation, the case undergoes a double fermentation, and thus its digestion and assimilation in the stomach are more readily secured. In his own practice, the most typical as illustrating the value of koumiss, was a phthisical patient.

Dr. BROADBENT, believing the case to be hysterical in nature, would look for an explanation of the details in the nervous condition of the patient, rather than in the food taken. This opinion, he considered, supported by the facts adduced. The nervousness, irregular menstruation, morning and evening vomiting, &c., pointing to the conclusion that it was an example of hysteria. It was an extraordinary case, and might take rank with the accounts of fasting girls, and similar cases.

Mr. LONGHURST inquired if any local treatment had been resorted to.

Dr. ROGERS suggested that the full significance of the case was not understood. His experience tended to convince him that there is an intricate association in such patients, between the various organs, depending on the nervous system.

Dr. O'CONNOR had found the application of nitrate of silver to the os of service in persistent vomiting. Prepared milk, and Valentin's extract of beef, in teaspoonful doses, he generally found well borne. He considered the prolonged expiratory murmur a peculiar symptom.

Mr. WILBERFORCE SMITH thought it important to know what diet had been employed before the koumiss was made trial of. He considered the patient's improvements as due to the physiological rest to the organs. Milk will not secure this, the effort at digestion being too severe (a strain; and in order to obtain perfect rest, all nitrogenous food needs to be abstained from. The vomiting might be nervous. Cream served as an admirable food; beef-extract was devoid of nitrogen, and non-nutritious. Injections of nutritive enemata were advisable.

Dr. STRETCH DOWSE desired to know how much koumiss had been given in the twenty-four hours. He considered this case to be similar in its details to others recorded, and recommended that fluids should be abstained from altogether for a day or two.

The PRESIDENT inquired if blistering the epigastrium had been tried.

Dr. SUTHERLAND said the koumiss used had been obtained from Chapman's, in Duke Street, Portland Place. Every other food tried on the patient had failed to be retained. She did no work. He did not believe her to be hysterical, though her voice somewhat resembled hysterical euphonia. She will not keep to her bed for any time, so that it is impossible to try such treatment with her. She was bad tempered at home, and sometime suicidally inclined. He had not applied silver nitrate to the os; the patient was over sensitive to examination. Physiological rest she had had in plenty; alone, it did not avail. Injections were equally useless to her. He had not tried the effect of blistering the epigastrium.

Mr. CHRISTOPHER HEATH on

A CASE OF GANGRENE OF THE ARM FROM A POISONED WOUND—AMPUTATION AT THE SHOULDER, AND RECOVERY.

The patient was a nurse, *æt.* 34, who, in laying out the body of a lady who had died of puerperal septicæmia, pricked her thumb with a pin. Notes of the puerperal case were given by the physician, who had attended her, and it appeared that she was a primipara in good health, and was the first patient attended by the accoucheur after his holiday, and that strict antiseptic precautions were employed. On the 4th day a rigor occurred, and the temperature was 105°, pulse 120. Subsequently the temperature went up to 107°, but was reduced to 102° by an ice-cap and water-bed. On the 7th day, however, the left pleura filled, and the patient sank. A nurse in attendance pricked her finger on the day of the rigor, and had a sharp attack of lymphangitis with recovery. The second nurse carried out the attendance till the patient's death. This nurse applied nitrate of silver to the puncture on the evening of the day she received it, and the next day the hand was swollen and painful. She had no further advice until the 4th day, when she was admitted to University College Hospital with the whole arm swollen and tense. Free incisions were made, but the next day the hand and fore-arm had gangrened. At first the gangrene seemed limited to the fore-arm, and the swelling of the upper arm decreased for a few hours, but a relapse taking place, Mr. Heath amputated at the shoulder-joint. The patient made a rapid recovery, and was discharged in a month. Mr. Heath remarked upon the virulence of the puerperal poison, and protested against the common practice of applying nitrate of silver to punctures received at post-mortem. He believed that the application of belladonna was most useful in cases of local inflammation, coupled with free incisions when necessary.

Mr. HARRISON CRIPPS recounted the history of the patient in St. Bartholomew's Hospital referred to by Mr. Heath. The man was scratched on the arm by a piece of iron gauze. When admitted the hand was black, and the arm above red. Free incisions were made into the back and palm; thick blood alone escaped. Inflammation spread to the upper arm and axilla, and Mr. Holden amputated the limb; the tissues at point of amputation seemed diseased. The pain was at once reduced in intensity; temperature fell from 103 deg. to 99 deg., and pulse to under 100. Rigid antiseptic precautions were observed, but six days after the operation gangrene reappeared, and spreading rapidly, the patient died on the tenth day. The interest of these two cases lay in the differing terminations; he believed death to be due in Mr. Holden's case to delay in am-

putating, and recovery in Mr. Heath's to early operative interference. It would be desirable to fix a definite rule for guiding procedure in cases demanding amputation.

The PRESIDENT.—These cases confirm the rule that in spreading gangrene amputation should be done at once. Pathology teaches that the gangrene is due to an organism, and in blood disease it is possible in some cases to speak definitely of it, e.g., *bacillus anthracis*. Dr. Cox has shown that progressive necrosis in spreading gangrene is due to a special organism by which the blood is unaffected, and Mr. Heath's case is especially interesting in this relation.

Mr. HEATH remarked that to the rule "amputate early" should be added "and high up."

Dr. J. WHIPHAM read a paper on

**SMALL ROUND-CELLED SARCOMA OF THE DURA MATER ENCROACHING ON THE LEFT TEMPORO-SPHENOIDAL LOBE OF THE BRAIN, AND PRODUCING EXTENSIVE SOFTENING IN ITS NEIGHBOURHOOD.**

A railway guard, *æt.* 35, was admitted into St. George's Hospital on January 25, 1880. He had served on board ship in former years, and when in foreign parts had suffered from ague, dysentery, and acute rheumatism. At the end of December, 1879, he caught cold, had rigors and pain in the chest, and dyspnoea, but continued his occupation as a railway guard. During the fortnight previous to his admission he had been laid up with headache in the frontal region. About thirteen days before he came under observation he felt unwell, and became languid, and on the day following he shivered and felt pain in the left frontal and temporal regions. The pain recurred in severe paroxysms, with intervals of entire cessation of pain. On admission, the patient was well nourished, but somewhat dull and stupid. His tongue was coated. Pulse, 72, small. He had severe headache, and said that he felt "stuffy in the head." The pain was referred to the left temporal region and to the left eye. There was a purulent discharge from the right ear, and Mr. Dalby reported a large perforation of the tympanic membrane. Shortly afterwards the patient became restless, and on the seventeenth day after his admission had passed into a comatose state, but still indicated, by gestures, that he was suffering pain on the left side of his head. Slight want of power in the right hand and leg was detected, but there was no real paralysis. The patient died on Feb. 21. He was a left-handed man. At the post-mortem examination a lobulated tumour was found attached firmly to the middle fossa of the skull on the left side, and extended into the substance of the left temporo-sphenoidal lobe of the brain, involving or causing softening of the anterior parts of the three temporo-sphenoidal convolutions, and the island of Reil. The softening extended to within 1-20th of an inch of the level of the upper surface of the corpus striatum, but did not involve that ganglion. The important feature in the case was its bearing on the question of localisation of the functions of the brain. Although none of the motor centres were actually involved in the disease, it seems more than probable that the pressure exerted by the growth must, to a certain extent, have interfered with the functions of those convolutions situated directly in the line of such pressure. Thus may be explained the partial loss of power which existed in the right arm and leg, seeing that the upward pressure of the tumour would more especially affect the posterior part of the left superior frontal convolution, the upper part of the ascending frontal, and probably part of the superior or posterior parietal lobule; those regions, that is to say, which Ferrier and others have shown to preside over the movements of the arm and leg. Further, the actual lesions which were demonstrated at the autopsy tend to show that the deafness in the right ear was the result rather of the injury to the brain than of the perforation of the tympanic membrane. Finally, the facts of the patient being a left-handed man, and the injury to the brain being on the left side, are interesting as bearing on the question of aphasia.

Dr. WILTSHIRE asked if an ophthalmoscopic examination had been made. He was reminded of a case said to be puerperal mania, in which perforation of the tympanum occurred. It was not puerperal mania, however, and on inquiry he found the patient had been subject to discharge from the ear for many years.

Dr. ALTHAUS—Were the special senses of taste and smell examined?

Dr. DOWSE said it would be interesting to know if the pain had been localised or extended generally over the cerebral

hemisphere, neck, and arms. He had seen cases of similar tumours in which the pain was thus distributed.

Dr. BROADBENT thought it interesting to notice the existence of a slowly growing tumour with acute symptoms, and also the effect on hearing. He attributed the effect produced to pressure set up by the tumour on the corona radiata, and not directly on the convolution. It was especially interesting, too, that the Island of Reil was diseased because of the localisation of speech in it by certain persons; the cutting off of the fibres passing between it, and the proper centre of the faculty would bring about such a result. He was struck by the absence of vomiting with the patient.

Dr. SILVER inquired how deep the injury must be before speech would be affected. He had seen a case in which during life speech gradually grew slower, and in which post-mortem examination showed that the Island of Reil was diseased.

The PRESIDENT said he did not quite understand whether Broca's convolution was affected in Dr. Whipham's case.

Dr. WHIPHAM replied that no ophthalmological examination had been made. Pain was confined to the frontal and left temporal regions; there was no vomiting from beginning to end; no lesion of Broca's convolution, the Island of Reil alone being complicated.

Mr. GODLEE showed a patient on whose case he and Dr. Sturge had read a paper, describing how the facial nerve had been stretched. Paralysis existed for thirteen weeks, and now the powers of motion were being slowly regained.

**SURGICAL SOCIETY OF IRELAND.**

A MEETING of the Surgical Society was held on Friday evening, January 21st, 1881, in the Albert Hall, Royal College of Surgeons, Dr. EDWARD HAMILTON, senior member of council of the Society present, in the chair.

Mr. TUFFNELL, Hon. Sec., read the minutes of the previous meeting, which were signed.

**SUPERIOR MAXILLARY BONE WITH TUMOUR ATTACHED.**

Dr. KILGARIFF exhibited a specimen of the superior maxillary bone and a tumour implicating it which he removed on the 13th inst. from a girl, *æt.* 13, a patient in the Mater Misericordiae Hospital. The growth had first made its appearance about eighteen months previous to her admission, appearing then as a slight protuberance in the facial aspect of the bone. It caused no pain, and but slight disfigurement. However, it continued to grow slowly, and latterly created such disfigurement and personal discomfort, owing to the difficulty of breathing, that she came to town and placed herself under his care. The disfigurement was very pronounced, the face on the right side presenting an appearance rather like that of a frog's cheek. He found that the growth extended from the last molar tooth but one to within a short distance of the symphysis. The tumour had caused depression of the horizontal plate of the superior maxillary bone, projecting downwards, and attaining the size of a sweet almond. As far as the tumour extended the alveolar arch was completely implicated, the swelling infringing on the right cavity of the nose, and completely blocking up that passage. There was no lymphatic gland implicated. After consultation, he determined to remove the superior maxillary bone, sparing if possible the orbital plate. He proceeded to do so after the method of Ferguson, and he removed the entire bone with the exception of the orbital plate, being fortunate in leaving the horizontal plate of the palate and avoiding injury to the velum. The tumour was exceedingly frail, and in the grasp of the powerful lion-forceps the alveolar and other borders were broken up into fragments, which he removed separately with his fingers. There was no cavity in the bone, the antrum being completely filled. Consequent on the absence from town of some of the histologists he had been unable to procure microscopic sections, but he himself leaned to the opinion that the tumour was not malignant.

Mr. W. THORNLEY STOKER read a communication  
ON A UTERINE TUMOUR

which he exhibited, with the uterus itself. The paper will be found at page 133.

Dr. HENRY KENNEDY, accounting for the kidney disease, said it appeared to him that the ureter had been involved as well as the urethra, and that the disease might have been

due to pressure on the ureter. The left kidney showed the greater extent of the disease, the author pointing out that the tumour occupied part of the middle of the abdomen, and extending mainly to the left side. Those tumours were apt to be numerous, and they took one direction, under the peritoneum, and again in the mucous membrane. In the College museum were beautiful specimens, showing the formation of the tumour in the centre of the uterus, then going down to the mucous membrane, and still further on, forming polypi. The case brought forward by Mr. Stoker was one of extraordinary interest, and particularly as regarded the double capacity in which the tumour showed itself; its mobility giving rise to great difficulty in the diagnosis.

Mr. STACK asked whether Mr. Stoker had traced the causes of the obstruction of the urine through the bladder to the urethra?

Dr. DOYLE asked was there hypertrophy of the bladder, which generally gave rise, by extension up the ureter, to dilatation at the pelvis of the kidney and pyelitis?

Mr. THORNLEY STOKER replied. In making a post-mortem examination he paid particular attention to the state of the lining of the membrane of the bladder as well as of the ureter and pelvis of the kidneys. The mucous membrane of the bladder was in itself healthy, and presented no appearance of suffering from the obstruction. However, that the obstruction existed was beyond question, and though it spared the bladder it attacked the more remote structure, the kidney. The ureters were not dilated, they were of normal size. Even though not affecting the bladder, the condition of the kidneys might be traced to a retention of urine. He held with the idea in reference to the passage of the tumour into the uterus to form polypi. There was no distinction between uterine fibroid and fibroid polypus of the uterus, though certain writers had endeavoured to make a distinction, characterising a tumour as being encapsuled and a polypus as not being encapsuled. That was explained by thinking back over the pathology of those growths. As long as the tumour remained a tumour, and not a polypus embedded in the wall, so long it had the so-called capsule of compressed muscular tissue; but as soon as it made its way out, the so-called capsule disappeared, and it became the polypus proper.

(To be continued.)

## Department of Lunacy.

### THE LIVERPOOL LUNATIC HOSPITAL.

No Annual Report of the Liverpool Lunatic Hospital is forwarded to us, nor can we ascertain that any official account of its condition and prospects is given to the public by its board of governors and medical superintendent. From the Report of the Commissioners of Lunacy, however, we obtain some information about it, and that is of so unsatisfactory a character that we feel called on to direct special attention to the state of the institution, and to the necessity which exists for reforms in it of a very sweeping description. The city of Liverpool is justly proud of her medical charities, and nothing but ignorance of the real state of the case can account for the fact that she tolerates in her midst a lunatic hospital that is anything but a model, that is condemned by all competent authorities, and that compares most unfavourably with similar institutions in other cities and towns. The public spirit and benevolence of Liverpool, when once awakened to the existence of a blot on her fair fame, will not, we are assured, sanction its retention, but will insist on changes, which will place the treatment of the insane in Liverpool on a level with the treatment of the mentally afflicted in other parts of the kingdom. Under present circumstances, the Liverpool Lunatic Hospital is a drag financially on the Royal Infirmary, with which it is connected, and altogether fails to fulfil the duty with a view to which it was established. While other lunatic hos-

pitals, designed to supply treatment to insane persons, who, although not paupers, are still unable to pay the charges usually demanded in licensed houses, are overflowing, and extending their accommodation yearly, out of their profits, the Liverpool Lunatic Asylum stands half empty, and is dependent for its working expenses on subsidies, drawn from a sister charity. While throughout the country there is heard on every hand, a demand for asylum accommodation for lunatics of the lower middle class, the Liverpool Lunatic Hospital, which stands in the centre of a populous district, in which the lower middle-class and insanity abound, has nearly one-half of its total number of beds unoccupied. It is clear that this institution has ceased to command public and professional confidence, and to attract patients of the class for which it was intended. And it is scarcely to be wondered at that it has done so. Placed in the heart of Liverpool, accessible to its dust and din, surrounded by prison-like walls, of a sombre and forbidding style of architecture, destitute of gardens and recreation grounds, meanly furnished, and lacking that organisation and those appliances that are now regarded as essential to the proper treatment of the victims of mental disease, it is uninviting, whether viewed from without or within. The clerk or warehouseman, or indigent professional man, whose wife or child has gone mad, may well be pardoned if he shrinks from consigning his loved one to such a gloomy receptacle, and accepts rather the degradation of an arrangement with the Board of Guardians by which admission is secured into the bright, cheerful, and thoroughly well-equipped county asylum at Rainhill. Pauper associations are painful, it is true, but these must be endured if the best chances of recovery from a terrible and crippling malady are inseparably connected with them. And thus it is that the present deplorable state of the Liverpool Lunatic Hospital works mischief in a variety of ways. It repels those whom it was meant to benefit; it tends to pauperise those in whom it might have helped to maintain a worthy spirit of independent pride, and it deprives the afflicted beings, for whom it fails to supply suitable treatment, of some of their prospects of recovery, for it cannot be doubted that lunatics of some education and refinement, will be less likely to recover rapidly and completely when compelled to mingle with the lowest and coarsest human off-scourings of a large sea-port, than they would be if sheltered from such ungenial contact.

The one and all-embracing evil of the Liverpool Lunatic Hospital is its position. Nothing can be made of it while it remains where it is, and no real improvements are practicable in the existing structure. The hospital ought to be removed into some country district, in the neighbourhood of Liverpool, and there re-constructed and re-organised on a thoroughly new basis. The necessity of this removal has been repeatedly and earnestly urged upon the governors by the Commissioners in Lunacy, and it does not certainly redound to the honour of the governors that they have altogether disregarded the representations thus authoritatively made to them. "We have only to repeat," say the Commissioners in their last Report, "the conviction which has been expressed by our colleagues with more or less persistency for the last fifteen years, that the best policy would be to dispose of the present land and premises, and remove into the country, and we feel sure that this Hospital would then be a boon to many, and not as it now is, of use but to a few." As the governors, after fifteen years indoctrination, have still failed to grasp an obvious truth, and by their dulness and inactivity, continue to cripple the usefulness of a

public institution, it would seem time to inquire into the constitution of the Board of Governors, and to ascertain whether an infusion of new blood amongst them might not quicken their apprehension of the fitness of things. The credit of the city of Liverpool is concerned in this matter, and we cannot doubt that when it is once brought before the citizens, fifteen months will suffice to give effect to the recommendations of the Commissioners, and to render the Liverpool Lunatic Hospital an attractive institution, for the care and treatment of a large class of the insane, now practically destitute of proper provision,—those of small means, but not paupers. Let a committee of philanthropic Liverpool men first inspect their own Lunatic Hospital, and then visit a few similar establishments, like the Manchester Lunatic Hospital at Cheadle, the Northampton Lunatic Hospital, the Barnwood Asylum at Gloucester, or Wonford House, at Exeter, and the necessary changes will not be long delayed. The wealth of Liverpool ought to provide freely and readily, whatever funds may be necessary for these changes, and perhaps the funds required to be raised by subscription might be small in amount. The present site of the Hospital must be very valuable, and it has been hinted that it affords the best possible position for the new Cathedral, which Liverpool is certain one of these days to erect. Whether sold for this or any other purpose, it would, probably, bring in a sum that would go far towards providing a new Hospital, not in the streets, but in the green-fields.

“SALUS POPULI SUPREMA LEX.

WEDNESDAY, FEBRUARY 16, 1881.

### THE DENTAL ACHIEVEMENTS OF THE MEDICAL COUNCIL.

THE one-day meeting of the General Medical Council which assembled on the 3rd inst. was, we venture to assert, one of its most satisfactory deliberative sessions, and, in

the brief period of its assembly, it served the medical profession more efficiently than on any previous occasion.

The very fact that it was a one-day meeting was sufficient to commend the sitting to special approval with those who are conversant with the dreary and unproductive wrangles of past times; but the peculiar success of the recent assembly arose from the fact that the Council in a few hours made itself as ridiculous, and displayed as clearly its disposition to shirk its duty as if it had employed its collective wisdom for a fortnight for that purpose.

The object of this meeting was to cobble up the dental business, which the Council had reduced to an almost hopeless muddle. Firstly, it had given its official consent to the passing of the Dentists' Act apparently without reading it; certainly without realising the fact that it was full of errors and imperfections, which would make its working as law an impossibility, and utterly unconcerned as to the fact that the status of registered medical practitioners was seriously threatened thereby. Secondly, the Council, without taking an adequate legal opinion as to its powers and responsibilities under an Act which placed upon it duties altogether different from those which it had previously been supposed to discharge, proceeded to register as legally qualified dentists whole regiments of persons of whom the only thing which could be possibly known was that they were *not* dentists in any true sense of the word. Thirdly, being pressed with remonstrances against this wholesale licensing of absolutely ignorant persons to practise a surgical speciality at the expense of the deceived public, the Executive Council became involved in a floundering effort to extricate themselves from the dilemma. First, they erased a number of names from the Register for misrepresentation; then they restored some; then they agreed to condone the misrepresentation and correct the entry; then they concluded to take legal advice, and then, brought to a helpless standstill in the focus of a muddle of their own creation, they decided to summon the full Council, and throw over the responsibility of the mess on them.

Hence the recent meeting. The work to be done at this meeting was to decide two questions in dispute:—

a. Whether a person who declared himself to be practising dentistry “in conjunction with medicine, or with surgery, or with pharmacy,” should or should not be removed from the Register upon proof that he was, in a legal sense, neither a physician, surgeon, or pharmacist.

b. Whether a person who obtained registration by declaring that he was “*bonâ fide* in the practice of dentistry” should be removed if it could be shown that his practice consisted in the drawing (or breaking) of an occasional tooth, and that his actual means of livelihood was some totally different trade, such as hair-dressing, or farming.

The necessary proofs on these points were supplied by the British Dental Association in several hundred cases, and that organisation demanded that the Council would do its duty, and expurgate the Register from persons thus fraudulently or erroneously entered therein; and the Association furthermore submitted the opinion of very eminent counsel that these persons were improperly registered, and that it was the duty of the Medical Council to

remove them. Here were two plain questions to answer, and, with characteristic left-handedness, the Medical Council answered neither. On the contrary, they obtained the opinion of counsel (eminent but not the least more reliable than those consulted by the British Dental Association), *not* upon the points which required to be decided, but upon an entirely different matter, *i.e.*, the legal propriety of a course which the Council had made up its mind to follow.

It is to the course thus determined upon that we wish to direct special attention, as a clear manifestation, not only of the incapacity of the Council to do its duty, but of the firm determination of that body not to touch any responsibility whatever—duty or no duty—which can be escaped from by any legal quibble, or by any sacrifice, however grievous, of professional interest. The Council had enrolled a great variety of persons as dentists—some with full medical and surgical degrees; some with special dental degrees; some with a recognised position as dental practitioners; some who practised dentistry in connection with the legal dispensing of medicines; a host who called themselves dentists on the strength of a brass name-plate of a few months' maturity; and a legion of chemists' boys, hairdressers, and other persons of a surgical calibre which needeth not to be defined. Did the Medical Council set to work honestly to find out who of their registrées had any right to be on the Register, or had any, even the remotest, claim to call themselves dentists? Not at all. They serenely decided not to enter on any such vulgar function, but to return the whole number, jewellers, hair-dressers, druggists porters, *et hoc genus omne*, as legally recognised practitioners in dental surgery. But they did worse than this. Determined that no inequalities of dental education should ever exist in the future, they declared their intention of levelling down all the well-educated dental surgeons to the level of these persons, by striking out of the register and ignoring altogether the degrees in medicine or surgery possessed by the more respectable registrées, and by striking out all words implying a higher walk in the profession, so that no person might, in future, be able to differentiate a surgeon practising dentistry from a hair-dresser who pulls teeth and shaves.

We leave it to the judgment of the profession whether these acts of the Medical Council do not justify us in thanking that conclave, in the name of those who look with longing to its reconstruction, for having done what even the late Dr. Andrew Wood could not find it in him to apologise for—for having displayed with audacity so open—its insolent contempt for its duty, and for both public and professional opinion.

There was, of course, the inevitable opinion of counsel upon which to hang the excuse for adopting such a course; but there was also the equally strong and equally reliable opinion to the diametric contrary. The real motive was that naively put into words by Prof. Humphry who, in moving the Council to act thus, said it seemed very important that they should strike out all superior qualifications or designations, for it would put an end to all questions which had arisen in such a large number of cases as to whether persons were properly entered upon the Register, or whether they had by misconception or by fraud added the words "in pharmacy," "in medicine and surgery;"

*and it would clear away at once the necessity for entering upon the consideration of the large number of cases mentioned in the Report.*

Certain members of the Council, indeed, seem to entertain a strange view of their duty under the Act. The 13th section says: "The Council *shall* cause to be erased . . . any entry . . . incorrectly or fraudulently made." And again, sec. 35 says: "Any person who wilfully procures . . . himself to be registered . . . by making . . . any false or fraudulent representation . . . shall be guilty of misdemeanour."

These clauses seem sufficiently plain, and yet we find the following pronouncements of speakers on this subject:

Dr. Aquilla Smith "assumed that some of these men had acted fraudulently in stating their qualifications, but the Council had nothing to do with that."

The President (Dr. Acland) said "they were not discussing whether persons were guilty of fraud, because that was entirely beyond the province of the Council."

We conceive that it is unnecessary for us to say another word. But detraction could not equal in effect the detraction of the Council itself by its own acts, but—being thus forced to give expression to our disgust and indignation in terms which we should not employ under less flagrant circumstances—we feel it our duty to offer our acknowledgements to Professor Turner and Mr. Macnamara, the only members of the Council who seemed to appreciate even remotely the principle that public and professional interest should be superior to legal quirks, and the performance of a solemn duty of trust of greater importance than all the discomforts which the responsibility of performing such duty might entail upon the executive committee. To the Council we say with all earnestness *macte virtute*. On no account take warning from the fate of obstruction in "another place," but fulfil the noble destiny selected by yourselves of working out the "problem" how not to do it. What does it matter that by this single day's proceedings you have estranged the confiding trust of the dental surgeons, and taught them the lesson of your incapacity which the medical profession has long since learned?

Thus you will confirm the character for ingenious incompetency already so well earned, and—let us hope—will continue to devote yourselves to the task of removing from the public mind the last lingering idea that a Council constituted as at present can have a shred of reason for its continued existence.

---

#### TOBACCO.

THE delights of tobacco have been sung by poets; essayists have extolled its praise; fanatics have sweepingly condemned, enthusiasts have extravagantly lauded it; but it yet remains either for the world to become the universal slave of tobacco-idolatry, or to unite in one crusade against the defenders of its excellence. No subject is more generally interesting; none more capable of exciting opinionated controversy; none more capable of meeting the sympathies of its partisans; scarce any so capable of evoking heated opposition from those who see in the increasing consumption of tobacco among civilised peoples, the most invincible proof of moral degeneracy and national ruin.

It is a misfortune that the advocates of any system of rigid ethics, must of necessity be of the ultra-prejudiced type; their system admits of no adjustments, it is hard, fixed, unalterable; whatever exists not in accordance with it, exists, in the sight of these good people, for evil only, and "evil is its good." They do not credit that natural differences, individual or general, can in any way influence the result of non-observance of their code; whatever is not in accordance with it is, in itself, unalterably wrong. In this way do the anti-tobacconists regard the consumption of the drug they so cordially detest; in this way do they elect themselves judges of mankind, and by their adjudication every smoker is a beast, and a miserable victim of certain destruction. By word of mouth, and by printed invective, scattered broadcast throughout the country, these champions of deprivation seek to prosecute their labour of recruiting the ranks of tobacco-rejectors; their plan of campaign, however, is not always to be defended from the suggestion of being conducted with a keener regard for success in their endeavour, than for the *causa sancta veri*. This is most clearly seen in the emotional pamphlets so familiar in connection with the anti-nicotine army. In them use is made of misunderstood quotations from manuals on *materia medica*, wherein the symptoms of poisoning by the tobacco alkaloid are detailed, and which in all their naked dreadfulness are displayed in leaded type before the mind of the unfortunate and terrified reader. Another favourite mode of procedure with the same tacticians is to obtain from some source the expression of a leading authority against the abuse of tobacco; armed with this, which they carefully strip of its modifying companion sentences, they then hurry before the world, and proceed to terrify afresh, with the increased force lent by the name they are able to attach to their fulmination.

We do not for a moment pretend that the excessive employment of tobacco is not an injurious practice, likely to carry with it, if long continued, a succession of physical ills that will seriously affect the bodily health; neither do we accuse the anti-tobacconist army of improperly stating these consequences. Nicotine does undoubtedly paralyse the terminal plates of motor nerves; and it leads, there can be no doubt, to degenerative changes in the great nervous centres, mainly through the disturbance of nutritional functions exerted through the circulatory apparatus. In other ways, too, it reacts injuriously on the human organism, and oftentimes the primary cause of persistent dyspepsia is to be sought in the tobacco habit. But the same series of charges may be laid against other articles in common use, and particularly can it be said of tea that its excessive use is attended with consequences in the highest degree inimical to the devotees of this beverage. But no one, on this account, would care to suggest that henceforth, every food found to create bad consequences when improperly or too frequently employed, should be totally rejected as a desirable or permissible addition to the diet. And yet in a sense, this is exactly the course marked out by the anti-tobacconists. They postulate the indefensible dogma, that tobacco is universally an evil, and seek to coerce, as far as they are able, the whole civilised world into an acceptance of the fact they have thus gratuitously erected into importance. To some men tobacco is pre-

eminently serviceable; it enables them to achieve work which, without the aid it renders, would be impossible to them, and would remain unperformed. It is idle to pretend that work done under such circumstances is of little merit; every reader of these lines will easily recall, not one but several, instances of men who, smokers by habit, rely on the habit to enable them to accomplish labour of intellectual greatness, and of inestimable value in advancing the progress of medical science. It would be an impertinence to mention them by name; but the eminence and authority attaching to them would, at any rate, be equally considerable with any that could be advanced in opposition to the testimony they could tender in defence of tobacco, or rather, it should be said, in vindication of what merit it possesses.

It remains to be said, and this the most inveterate smoker will concede, that for young persons the habit is unmistakably a bad one. During the period in which the physiological activity of the body is at its highest, it is simply injurious to so interfere with its functions as shall in any way disturb the harmony existing between them. Tobacco smoking achieves the disturbance of interference with the digestive functions first, and subsequently by complicated nervous changes depending on retarded nutrition of the tissues; and at a time when the growing organism is specially in need of every assistance, to meet the needs of its development, it cannot be but intensely injurious to it that any portion of its force shall be alienated from its legitimate office. The system suffers, and the boy degenerates until his condition becomes altered and attuned to the life-long exhibition of the evils of premature and continued indulgence in tobacco smoking. The anti-tobacconist, however, is by no means thereby justified, in assuming that the same cause is productive of the same results in every case. This he does unwarrantably. The physiologically perfect man, in whom the exchanges are periodically balanced, is in a wholly different position to that of the boy; the former is in a state to profit by the aid in procuring repose, which tobacco affords; and the first effects of the drug overcome, and the system accustomed to its influence, it exerts a beneficial effect rather than other. Here again, excessive indulgence, as with any other thing good in itself, is bad in the extremis;—but avoiding the objectionable term, "moderation"—inade of incipient toxic effects, it will do no harm.

#### THE THREATENED SMALL-POX EPIDEMIC.

In the House of Commons on the 10th inst., Mr. Dodson, President of the Local Government Board, replying to Mr. Torrens, said it had been alleged that the aggregation of small-pox patients in the hospitals of metropolitan asylums had been attended with an outbreak of small-pox in the surrounding houses, and he had recently directed an inquiry to be made to ascertain whether that allegation was well founded. Until that inquiry had been completed it would be premature for him to express any opinion on the subject. There was no doubt that the average number of deaths from small-pox in the interval since 1870 had been largely in excess of that of the previous 11 years; but that arose from the fact that the latter

period included the very exceptional year 1871. The deaths since 1870 amounted to 15,533, of which 7,878, or more than one-half, occurred in 1871. If, however, the twelve years from 1860 to 1871 were compared with the nine years from 1872 to 1880, it would be found that in the latter period the average number of deaths was only 850 against 1,425 in the former period. As regarded the steps taken to prevent the disease, he had recently caused circulars to be addressed to the various sanitary authorities and boards of guardians, pointing out the measures to be adopted with a view of securing vaccination and re-vaccination, as far as practicable; and he was glad to be able to state that the local authorities generally had made a ready response to that appeal. Within a fortnight 330 acute cases of the disease were received into the hospitals of the Metropolitan Asylums Board. It is accordingly feared that should the number of admissions continue at the same rate, all the accommodation the managers have, or can provide, pending the decision of the House of Lords in the Hampstead Hospital case, will speedily be exhausted. The necessity is, therefore, pointed out for the various sanitary authorities and boards of guardians to supplement the action of the Board by making provision for the accommodation of any additional cases of small-pox that may arise in their respective districts.

The Metropolitan Asylums Board, with a view as far as possible to meet the immediate requirements of the metropolis under this sudden increase of small-pox, proposed to increase by sixty the number of beds devoted to patients affected with that disease in the Fulham Hospital. Against that measure a protest has been raised by the ratepayers of Chelsea, chiefly on the ground that although such hospitals are inevitable, yet cases from the whole metropolis should not be conveyed through miles of thoroughfares to a few districts; and they have proposed that instead of such a system each district should provide accommodation for its own sick. A deputation has been appointed to confer on these subjects with the Metropolitan Asylums Board and the Local Government Board. The question having been raised whether or not more cases of small-pox are contributed from small areas around the hospitals than there are from other and very much larger areas, a definite answer to this query would go far to decide the relative advantages of the few large hospitals for small-pox such as exist at present, and the numerous smaller hospitals in individual districts, such as are proposed.

## Notes on Current Topics.

### Competitive Examinations for the Services.

For the competitive examination for medical appointments in the Public Services held at Burlington House on the 14th inst., the number of names given in were, for the army 66, India 40, and navy only 8. The candidates for the first-named service contained among them a considerable number of high-class students; with regard to those for the second, it has been stated that among their names there are several which betoken Eastern nationality; and with reference to the last-named service, the result shown justifies the remark we recently made, that the delay in

propagating the expected Warrant has prevented candidates from coming forward. It is said that, instead of going to Netley, there to undergo a course of probation, the successful candidates for the navy will proceed at once to one or other of the large naval hospitals, there to be trained as heretofore in the actual duties pertaining to their position. Does this mean that a similar course will bye-and-bye be followed with regard to those for the two other services named? No doubt a considerable money saving would be the result, and, in other respects, advantages might be looked for in due time.

### The Spirit Ration in the Navy.

A DEPUTATION from the National Temperance League waited, last week, upon Lord Northbrook at the Admiralty with regard to the spirit ration in the navy. His lordship informed the deputation that the Admiralty Board intended to stop the issue of the rum ration altogether to the officers, but give them some compensation, so as not to make money out of it. They were going to stop the rum ration to the boys up to the age of 20, and to give further inducements to the men to give up their rum rations by giving them, besides the tea and sugar they were now allowed, a ration of soluble chocolate in the middle night watch. We shall watch with interest the results in regard to health that follow this measure. When, in the first quarter of the present century, tea, cocoa, and coffee were introduced into the dietary of the British sailor, the innovation was opposed on the grounds that the use of those beverages was effeminate. Notwithstanding much opposition, however, Captains Bowen and Forrest persevered in their endeavours thus to mitigate drunkenness in the fleet. Half a century has elapsed since then, and now their plan receives this further development.

### The Netley Medical School.

THE Winter Session of the Army Medical School came to an end on Monday week, the Herbert Medal and other prizes being presented to the winners of them by the War Secretary. In connection with this event we take occasion to notice a recent innovation in the system of competition for admission to the Army Medical Department, which seems to us well calculated to discourage work and make idlers and bad officers of the majority of the medical cadets who pass through that School. Heretofore a competitor ranked for an appointment, and for seniority amongst his fellows, according to the position which he gained by the combined marks of his examination at Burlington House when entering the school, and at Netley when leaving it. This was an excellent arrangement, because it encouraged the student to devote himself with ardour not only to his first examination in general professional subjects, but to the specialities of his military profession, in which he was instructed at Netley, and thus the service secured a good practitioner and also officer, specially competent for the needs of the soldier. We regret to say that, by a recent regulation, this system has, as regards the Home service, been changed. The cadet intended for the British Service ranks in the department solely upon the marks which he wins at the first examination at Burlington House, and having once put that ordeal over his head, has no inducement to

trouble himself with special work at Netley unless he be one of those rarely assiduous students who goes for the Herbert Medal or some other prize.

We would not for the world suggest that Netley cadets for the Home Service have been, by this change of rule, induced to idle. Such a statement would, of course, be calumnious; but as students are but men, it is pretty clear that they will not work if the stimulus to labour is withdrawn. Why it should be that a cadet intended for India should be exempted from this new rule, and should take his rank on the combined answering of his two examinations, whilst his *confrère*, who is to stay at home, is to be placed by his success at one only, is one of those mysteries of departmental management which the un instructed intellect is not permitted to understand. We would be well pleased if an explanation can be given of the existence of an anomaly so hurtful to the *prestige* of the British Army Medical Department of the future.

#### The "Indian Medical Gazette," and the Allahabad Libel Case.

SOME months ago certain criticisms with regard to an advertisement, signed by an officer of the Indian Medical Service, stationed at Allahabad, appeared in the *Medical Gazette*, published in Calcutta. The medical officer referred to considered that the comments contained therein exceeded the limits of fair public criticism; he accordingly raised an action for libel against the editor and the publisher of that paper, and, in the first instance, obtained a verdict against the former. But this victory was not of long duration; the action, on appeal, was brought before the High Court of Allahabad, with the result that the conviction first obtained was reversed, and thus the freedom of honest public criticism vindicated.

In a Supplement to a recent number of this *Gazette*, the editor gives what appears to be a fair, manly, and straightforward summary of the circumstances which led up to the unfortunate episode alluded to. He states very clearly, and he deserves every credit for what he says, "that we never meant to cast the shadow of an aspersion on the general character" of the surgeon referred to. "Nor did we intend to disparage in any way his philanthropy and professional zeal;" moreover, "we are prepared to go farther, and to declare our sincere and unfeigned regret that any remarks, which we found it necessary to make," "hurt his feelings." The only question which appears to have presented itself to the editor, was whether a separate hospital for diseases of the eye was required at Allahabad, considering that an institution, already existed at that station, where cases of those affections, as of all other forms of disease, were fully attended to. With reference to the expense and annoyance connected with defence in the action "now emphatically quashed," the editor reminds his readers, and all who have served in India will sympathise with him, that medical journalism in India is a labour of love rather than a business; "we snatch a few hours from a busy life to co-operate with others in keeping the lamp of medical science alight in this country;" "we strive to fulfil the function of being an organ of medical opinion." He further adds, and the statement does credit to his liberality of spirit, "if the facts and opinions which we promulgate are erroneous, we invite and welcome cor-

rection, and do our utmost to amend them;" but he remarks, if all our lapses or fancied lapses are to be visited by the rude rod of the law, "medical journalism will become, instead of a pleasure and enlightenment, a painful task which few, indeed, will care to undertake."

Our own opinion is that this case ought really never to have been brought before the public at all; that there was, in itself, nothing whatever to justify the prominence it attained in India; and that now, the sooner it is relegated to oblivion, the better it will be for all parties concerned.

#### The Sheffield Case.

THERE are several details connected with the revelations made at the trial of a nurse recently at Sheffield, on a charge of poisoning her charge, that carry an instructive lesson with them. Chief among them is the evidence afforded that the nurse of the present time is oftentimes disposed to assume an authority to which no claim can rightly be laid by her, and which may possibly be exercised to the disadvantage of the patient. In one sense it would seem to be a natural outcome of the publicity given to the nursing scandal at Guy's Hospital, that nursing attendants generally, should be led to attach exaggerated importance to their office, and regard themselves as the deputy, rather than the assistant, of the medical attendant. In the absence of the doctor, they frequently now undertake the duties proper only to him; and in some cases do not hesitate to resort to direct treatment of the kind which they consider to be adapted to the case under their care. For this the education they receive is primarily to blame. In certain of the institutions from whence nurses proceed, these latter are not infrequently taught that they are to look upon themselves as in some sort responsible for the progress of the patient; and, inflated with an undue sense of their importance they hasten, when opportunity offers, to put into requisition the smattering of professional knowledge they have been able to acquire during their hospital career. That this is calculated to do considerable harm is evident; and, as was suggested in a daily contemporary, it is possible that the Sheffield nurse, under the impression that her charge required sedative treatment, may have resorted to it, on her own authority, without special orders from the medical attendant. We are prepared to imagine that there are many nurses of the new school who would pursue such a course; and we assert that the system under which they were educated is to blame for the evil consequences resulting from it. It is high time a definite line was drawn between the duties a nurse may discharge, and those which, under no circumstances, she is to undertake. This is a matter of general professional interest; the profession ought to be speedy in seeing to it.

#### Another Nursing Difficulty.

THE Rugby Hospital is at present the scene of one of those troublous occurrences, the repetition of which is frequent enough to create serious apprehension. In consequence of grave interference with the execution of their duties, and a disregard of the orders given by them for the welfare of patients under their control, the whole of the physicians at this hospital, with one exception, have felt it necessary to resign their positions on the staff. This proceeding will be generally commended as a fitting

vindication of the dignity of the profession ; and, though it will probably tell severely at first on the gentlemen who have thus acted, it must be felt that they are fully justified in thus protesting against any infringement of their absolute authority in the wards of the hospital. It is said that the matter is to be brought before the Birmingham and Midland Counties Board of the British Medical Association ; but it may well be asked in what way this is likely to affect the question at issue. In the way of ventilating the grievance it may do good, but beyond this there is little likely to follow from any consideration the Association can give it. As possessing any power of enforcing redress, the body is useless ; it might be otherwise, but the powerful influence possible to a great union like the British Medical Association, is wholly wanting to it, as events have proved in the past, and are likely, we fear, to prove in the future.

### The University of Durham.

THE action of the Royal College of Surgeons in abolishing a special preliminary fellowship examination, threatens to be productive of evil consequences to those students who intended by aid of it to graduate in medicine at the Durham University. This latter body has, in recent years, permitted candidates for its degrees, to substitute the college fellowship preliminary, in lieu of its own Arts examination, and thereby opened its doors to a large number of young men, who had else been unable to proceed to it, by reason of the time required to prepare for a rigid examination in the arts subjects. It now, however, declares its intention of requiring future aspirants to the distinction of the Durham degree to undergo a slightly modified B.A. examination, that, viz., arranged some time ago for medical students ; but for which, subsequently, it was agreed to accept the college test. It is sincerely to be hoped that the senate of the university will reconsider the determination, and consent to a less comprehensive scheme than that they propose to reinstate. Unless they do so, a very material injury will be done to the rapidly growing favour into which Durham has recently sprung, among medical students, and those senior qualified men who seek to add a university distinction to such as they already possess. The vast improvements made in connection with the medical school at Newcastle, too, will be materially less productive than they might be made, if the decision be adhered to ; and on every ground there is the strongest reason for making any new examination, while being a fair test of general education, at the same time of a kind that a student of intelligence and industry would not find it too serious a matter to undergo.

### The Registrar-General's Quarterly Return.

THE return of the Registrar-General for the quarter ending December 31st, records the births of 264,562 children, and 166,640 deaths, the natural increase of population being thus 97,922. The annual death-rate for the whole kingdom was 19.2. The prevalent zymotic diseases in England were scarlet fever and diarrhoea ; small-pox, fatal cases, numbered 208. Salford and Sunderland possessed the highest death-rate. We shall refer again to the record for the year 1880.

### Sentence of Hard Labour on a Surgeon.

WITH much pain we have to record a serious case of unprovoked assault by, and conviction of, a Manchester surgeon. The most charitable construction we can place upon the case is that pleaded by the prisoner's counsel, viz., drink, under the influence of which his client lost all control of himself, and became more like a madman than one sane. The action was tried on Friday last, although the assault took place nearly a month since, the plaintiff being Mr. Thos. Crofton, a solicitor, and the defendant, Mr. W. B. F. Eames, L.R.C.P. Ed., L.R.C.S.I., both residing in Manchester. At the opening of the case Mr. Nash, for the prosecutor, said that as the prisoner had pleaded guilty he did not wish to make any comment on the case. On the 20th January Mr. Crofton was returning home in the evening. When he got to his own door he saw that a person was making a disturbance next door. He went inside, and shortly afterwards heard the prisoner at his own door calling on him to come outside. He asked him to go away, when the prisoner pulled him off the step and threw him down. Mr. Crofton put out his arm to break the fall, and it was dislocated at the elbow. The prisoner then kicked him several times. Mr. Blair, for the defence, said that the prisoner was excited by drink. He expressed deep contrition, and was willing to either give Mr. Crofton some compensation, or to pay a fine to the Crown. The Recorder said that the assault was entirely unprovoked, and he could not make any exception in the prisoner's case, because he was of a higher social standing than the majority of persons who committed assaults. The sentence of the Court was that he should be imprisoned for three months with hard labour.

The sentence is, of course, a severe one to a man like the prisoner ; but we cannot cavil at the Recorder's view of the case. Drink would be but a small excuse for an uneducated vagabond ; it should be none for one who occupies the position of a gentleman.

### The Wounded in South Africa.

ACCORDING to published reports an ambulance train fell into the hands of the Boers shortly after the affair at Lang's Nek. As a result of that serious loss, the reports regarding sufferings of the wounded upon the field which reach us seems very much as a matter of course. After the severe action of the 8th inst. it is said that the surgeons remained on the field all night tending the wounded ; that of the conveyances sent with wounded in them towards Newcastle six were disabled, that the injured men in them were exposed to heavy rain all night, and to other causes of suffering incidental to their unfortunate position. It is further stated that Dr. Macgahan had arrived at Fort Aimee with thirty-five of the less seriously wounded ; that forty remained on the field, but that waggons were being sent whereon to remove them, and, it is gratifying to learn that the Boers were behaving towards them with great kindness. Notwithstanding all that, the sufferings of those left upon the field were very great ; they had no water to drink ; wind and rain continued all night ; in fact, their lot was such as is to be looked for on occasions of battles against an European or other resolute enemy. It was ostensibly with a view to meet all the requirements of war

that the recent changes were introduced into the Army Medical Service. When the establishments suffer by capture, as on the late occasion, what is left of them must necessarily be insufficient; but it is matter of serious doubt whether, even in their complete state, according to "regulations," they are equal to requirements in a war such as is now in progress in South Africa.

### Metropolitan Hospital Sunday Fund.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund was held at the Mansion House on Monday last, the President, the Right Hon. the Lord Mayor, occupying the chair. The proceedings were for the most part of a formal character, as the re-appointment of the hon. secretaries, Sir Edward Currie and R. B. Martin, Esq., M.P., the General Purposes Committee, and the Committee of Distribution for the year, Mr. Custance being unanimously re-elected to the office of Secretary. A second donation of a hundred guineas towards the Fund, was announced from the trustees of the late Mr. James Drew. We observe that a contemporary has fallen into the error of supposing the Council intend to invest such sums and others which may from time to time be devised or bequeathed to them. This is an entire misconception, for as we understand the matter, all monies as those above-mentioned will be added to the current year's collection, and, as a matter of course, form a part of the Hospital Sunday Fund of June next. Donations have hitherto formed no inconsiderable portion of the general collection, as may be seen from an analysis of that of the past year, 1880. Of the £30,000 received, the Church of England congregations contributed about £22,000, the Independents £2,000, the Baptists, £1,100, the Roman Catholics £500, whilst the rest was made up of the contributions of other religious denominations, and to donations sent direct to the Mansion House.

### The Health of Ireland.

THE average annual death-rate per 1,000 for the week ending Saturday, February 5, 1881, represented by the deaths registered last week in the sixteen principal town districts of Ireland was 45.0, the respective rates for the several districts being as follow, ranging in order from Wexford, 25.8, to Limerick, 74.0.

The deaths from the seven principal zymotic diseases in the 16 districts were equal to an annual rate of 4.3 per 1,000. Six more deaths from whooping-cough were registered in Belfast, and 3 more from scarlatina in Limerick. Three deaths from measles were registered in Kilkenny, and 2 from typhoid or enteric fever in Queenstown.

Seventy-three of the 154 deaths from all cases registered in Belfast were ascribed to diseases of the respiratory organs other than phthisis, and 19 to that disease.

The mortality, last week, in 20 large English towns, including London (in which the rate was 27.1) was equal to an average annual death-rate of 28.0; in Glasgow, 33.9; and in Edinburgh 18.9.

In the Dublin District the deaths represent an annual rate of mortality of 46.3. Forty-four deaths from zymotic diseases were registered, being 2 under the number for the preceding week, but 3 over the average for the fifth week of the last ten years; they comprise one from small-pox,

3 from scarlatina, 3 from diphtheria, 5 from croup, 6 from whooping cough, 15 from fever (10 typhus and 4 typhoid or enteric, and 3 simple continued fever), 1 from erysipelas 1 from diarrhoea, &c.

The registered deaths (10) from typhus, are 3 in excess of the average for the preceding five weeks, and also 3 over the number for the week ending the 29th ult. Forty-one new cases of this disease were admitted into the principal hospitals, being 11 under the admissions for the preceding week, but 4 over the number for the week ending 22nd ult. Forty-two typhus patients were discharged during the week, 8 died, and 155 remained under treatment on Saturday last, being 9 under the number in hospital at the close of the previous week. The registered deaths (4) from typhoid are equal to the average for the preceding week, but 4 under the number for the week ending 29th ult. Only 4 new typical cases were admitted into the principal hospitals during the week.

THE Hunterian Oration of the present year was delivered in the theatre of the Royal College of Surgeons, on Monday afternoon last, by Mr. Luther Holden.

AT the Annual Dinner of the French Hospital on Saturday last, the chair was taken by the French Ambassador, M. Challemeil-Lacour. Several other ambassadors and a distinguished company were present. £2,000 was subscribed in the room.

AT the Annual General Court held of the Governors of Charing Cross Hospital, Mr. J. Astley Bloxam, F.R.C.S., was unanimously elected Surgeon, vice Mr. Francis Hird, F.R.C.S., who retires from active duties in connection with the Hospital, to become Consulting Surgeon thereto.

ON Saturday evening Dr. Richardson, F.R.S., delivered the first of a course of nine lectures in the theatre of the Society of Arts, under the auspices of the Ladies' Sanitary Association. At the close of the series Mr. Edwin Chadwick has promised two prizes of ten and five guineas respectively to the two best informed competitors of the subjects of the lectures.

WE record with much regret the very alarming illness from typhus, caught in the discharge of his duty, of Dr. Edward Peele, of Dublin. He was first taken ill on last Thursday week, and though his symptoms at first were such as to cause the greatest apprehensions, his progress during the last three days has been most favourable.

WE wonder if a little common sense will be developed now that Sir Richard Cross, Home Secretary under the Conservative administration, has been elected on the Board of Governors of Guy's Hospital. A few such clear-headed thinkers among the body would soon put matters straight at that unfortunate institution.

THE regulations for the International Medical and Sanitary Exhibition, which is to be held by the Council of the Parkes Museum of Hygiene at South Kensington, from July 16th to August 13th this year, were finally decided upon at a meeting of the committee last Wednesday, Feb.

9th, and the full prospectus with forms of application for space is now ready for intending exhibitors.

In the principal large towns of the United Kingdom, the rates of mortality last week were Edinburgh 19, Newcastle-on-Tyne 20, Leicester 21, Sheffield 22, Bradford 23, Portsmouth 24, Birmingham 25, London 27, Nottingham 27, Hull 27, Salford 27, Plymouth 28, Wolverhampton 28, Leeds 28, Brighton 30, Sunderland 30, Bristol 30, Norwich 30, Oldham 33, Glasgow 34, Liverpool 36, Manchester 37, and Dublin 46.

SCARLET fever showed the largest proportional fatality in Glasgow, Norwich, Sunderland, and Oldham; and whooping-cough in Edinburgh, Leeds, and Liverpool. Of the 31 deaths referred to diphtheria, 12 occurred in London, 3 each in Edinburgh, Dublin, and Bradford, 2 in Liverpool, and 2 in Birmingham. The death-rate from fever, principally enteric, was highest in Dublin, Nottingham, and Sunderland. Small-pox caused 58 more deaths in London and its suburban districts, one only in Dublin, but not one in any of the other large towns.

At St. Vincent's Hospital Dr. John A. Byrne removed an ovarian cyst from a young woman, æt. 23, on February 4. It had been growing for about fifteen months, and at the time of operation the umbilical measurement was 43 inches. The cyst was unilocular, contained 16 pints of fluid, and was completely free from adhesions, although from some symptoms previous to the operation it appeared likely that adhesion existed. The pedicle was secured by ligature, thermo-cauterised, and replaced. No bad symptoms set in from the time of operation, and the patient is convalescing, being in her ninth day; bichloride of methylene being the anæsthetic employed. This is another addition to the list of recoveries after this formidable but useful operation performed in the Dublin hospitals.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

GLASGOW MEDICAL JOURNALISM.—A blow has fallen on the *Medical Press and Circular*, we have actually been "boycotted" by the *Glasgow Medical Journal*! We are informed by its sub-editor, to whom the doubtless disagreeable duty of the execution of justice seems delegated, that he regrets to have to intimate that "we find it impossible to continue our exchange with the *Medical Press and Circular*. Our publisher has accordingly received instructions to remove the name of your publication from our list of exchanges." The veil of our literary Temple may well be rent, when the benignant face of Joseph Coats is averted from its porch! "Les petits esprits sont trop blessés des petits choses; les grands esprits less voient toutes, et n'en sont point blessés."

THE DEATH-RATE OF GLASGOW.—Nothing can be more striking than the fluctuation of the death-rate of a large community with changes of temperature. During the intensely cold weather recently experienced in Glasgow, the death-rate rose, with a sudden bound, to 39 per 1,000 or

more; now that milder weather has set in, it is materially reducing, though still it is at the unusually high-rate of 34 per 1,000 (Feb. 6), as against 39 per 1,000 for the previous week. For the corresponding weeks of 1878, 1879, and 1880, the figures were 30, 27, and 25 respectively. What have our enlightened sanitarians to say to this? We thought the medical milk company would have stamped out disease altogether!

THE HEALTH OF EDINBURGH.—A meeting of the Public Health Committee of Edinburgh was held on the 8th inst. The report of the medical officer for the month of January showed that the number of deaths was 457, equal to a death-rate of 24·10 per 1,000, while the death-rate for the same period of the preceding five years was 24·06. During the month 195 cases of scarlatina had been reported, of which 87 were in the new town, 88 in the old town, and 20 in the southern suburbs. The medical officer stated that during the past few months the epidemic of scarlatina had been steadily decreasing, and during the past few days it has almost entirely disappeared. Several cases of insanitary houses in the old and new towns were reported and ordered to be summarily dealt with, the parties interested being called upon either to put the premises into a proper state of repair, or to shut them up. A marked improvement was reported to have been effected in connection with the smoke nuisance at the Royal Infirmary. By the members of committee present at the meeting an opinion was expressed in favour of the purchase by the Corporation of the whole of the Old Infirmary buildings, and the utilising of a portion of them for the treatment of cases of infectious diseases. A representation having been made to the committee regarding the alarming increase of small-pox, which has recently taken place in London, the medical officer was instructed to have a ward prepared in the Canongate Hospital for the reception of such patients in the event of an outbreak of the disease in Edinburgh. Dr. Littlejohn stated, however, that it was gratifying to know that no cases of small-pox had yet been reported in the city.

EDINBURGH ROYAL HOSPITAL FOR SICK CHILDREN.—The number of patients treated at this Hospital during January last was 381. Of these 63 were in the Hospital on 1st January, and 38 were admitted during the month; while 261 were treated at the dispensary, and 19 were vaccinated.

ABERDEEN—MEDICAL OFFICER OF HEALTH.—We have much pleasure in recording that the municipal authorities of Aberdeen have resolved upon the enlightened course in this matter, which we recently indicated. At a joint meeting of the Public Health, and Watching Committee of the Town Council, held on the 8th inst., it was unanimously resolved to recommend that the offices of medical officer, police-surgeon, medical attendant at the gas works, analyst of the quality of gas, and inspection of byres, under the conditions of the Contagious Diseases (Animals) Act, should be conjoined, and the person appointed to perform the whole duties at present devolving upon the various officials named. It was resolved to recommend that in the meantime, at any rate, the office of public analyst should not be interfered with. The Committee further recommended that a salary of £300 per annum should be attached to the appointment, the person appointed to give his whole time to the discharge of the duties of his office. The proposed salary is about £80 in excess of the total sum at present paid in connection with all the offices.

VITAL STATISTICS OF LARGE TOWNS.—From the Registrar-General's weekly returns for the eight principal towns of Scotland for the week ending Saturday, February 5, we

learn that the death-rate was 28·9 per 1,000 of estimated population. This rate is 2·1 above that for the corresponding week of last year, but 5·8 below that for the previous week of the present year. The lowest mortality was recorded in Greenock, viz., 18·4 per 1,000; and the highest in Perth, viz., 35·1 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3·7 per 1,000, being 1·2 less than the rate for last week. Acute diseases of the chest caused 261 deaths, being 87 less than the number for the previous week. The mean temperature was 38·2, being 9·9 above that for the week immediately preceding, and 2·1 below that for the corresponding week of 1880.

**HEALTH LECTURES FOR THE PEOPLE.**—On Saturday evening, the 5th inst., the concluding lecture of the first series of "Health Lectures for the People," was delivered in the Free Church Assembly Hall, Edinburgh, by Dr. Smart, on "Preventable Diseases and their Causes," before a crowded audience. Dr. Smart began by explaining that under the title of his lecture, were included for the present, only such as came under the head of what were called "zymotic diseases;" that group of diseases which were more directly amenable to, and affected by public measures of prevention, and the conditions which obtained in large communities. A preventable disease might be described as one which arose or spread in consequence of the wilful, careless, or ignorant violation of those laws, the proper observance of which we know to be necessary to insure the preservation of health, and avert the spread of disease. The chief of the zymotic diseases were small-pox, typhus fever, typhoid fever, scarlet fever, diphtheria, measles, and Asiatic cholera. He then went on to consider them from the following points of view:—First, the injury they inflicted; secondly, how they originated; thirdly, their distinctive characters; fourthly, the conditions under which they spread; and fifthly, the means necessary for their control and prevention. In the course of the lecture, Dr. Smart adduced the figures of Mr. Simon, to prove the necessity for the rules he wished to enforce, from which it would be seen that 120,000 deaths from these diseases resulted annually in England and Wales alone. If they added those from Scotland and Ireland from the same causes, the total mortality was over 150,000, every one of which was a needless death.

#### FEVER CERTIFICATES.—THE IRISH COLLEGE OF PHYSICIANS.

THIS College has modified its previous arrangements with reference to certificates of attendance on fever. It had been ordered that for the future—

"On and after January 1st, 1881, every candidate for the license in medicine shall be required to produce evidence that he has, for not less than three months, studied fever in a recognised clinical hospital, containing fever wards, and recorded from daily personal observation, at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature."

The modification now decreed by resolution adopted on the 11th inst. is that the foregoing bye-law be not compulsory in the case of students who had commenced their necessary hospital attendances before October, 1879.

#### ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—BELFAST BRANCH.

THE thirty-eighth annual meeting of this most excellent society was held on the 2nd inst. The attendance was very influential.

Dr. T. H. Purdon, permanent president, occupied the chair.

Dr. Arnold, hon. secretary, read the minutes of last meeting, which were confirmed.

It was intimated that several letters of apology had been received.

Dr. Browne, R.N., J.P., presented the financial statement, duly audited, for the past year, which was passed; and the thanks of the meeting were tendered to the auditors. Dr. Browne observed that, in addition to subscriptions, he had received a bequest of £25 from the late Miss Patrick, of Ballymena, who had been for many years a subscriber to the society.

It was resolved that Dr. Cuming be requested to address the students of the Royal Hospital on behalf of the society.

Dr. Drennan moved, and Dr. Esler seconded, "That the marked thanks of the society are due and are hereby tendered to the president (Dr. T. H. Purdon), the honorary treasurer (Dr. Browne, J.P., R.N.), and to their honorary secretary (Dr. Arnold), for their very valuable services.

These gentlemen were re-appointed.

The following were elected, on the motion of Dr. Spedding, seconded by Dr. Browne, as a committee of management for the ensuing year:—Dr. T. H. Purdon, sen. (president), Dr. Browne, R.N.; Dr. Arnold, Dr. Ferguson, Dr. Drennan, Dr. C. D. Purdon, Dr. Murney, J.P.; Dr. Cuming, Dr. M. Cleery, Dr. Harkin, J.P.; Dr. Moore, Dr. M'Gee, Dr. Alderman Whitaker, Dr. J. T. W. Smith, Dr. Bryce Smyth, Dr. John Moore, Dr. Spedding, with Dr. Musgrave, Lisburn; Dr. Ross, Ballymena; Dr. R. B. M'Clelland, Banbridge; Dr. Filson, Portaferry; Dr. Gray, Castlewellan; Dr. Higginson, Bangor, as country members.

After some further routine business the meeting separated.

## Literature.

### SHORT NOTICES.

(1) "Cottage Hospitals; General, Fever, and Convalescent." By Henry C. Burdett. Second Edition. London: J. & A. Churchill.

(2) "The History and Therapeutical Value of Arsenic in Skin Diseases." By Malcolm Morris, F.R.C.S.Ed. Macmillan.

(3) "On Some of the Terms in Common Use among Medical Men." By A. Rabagliati, M.D. Bradford: W. Byles & Son.

(4) "The Treatment of Chronic Rheumatoid Arthritis." By J. Fletcher Little. Leeds: Jackson.

1. The name of Mr. H. C. Burdett is now intimately associated with the development of cottage hospitals, a movement which has now taken a firm hold in this country, and which has been attended with the most beneficial results. In this work he has given the history of its rise, and still more, he has written a handbook, in which everything may be found relating to cottage hospitals, so that any charitable person disposed to erect one, need only purchase the work, and proceed upon the lines indicated, and he will be able to carry his scheme to a satisfactory conclusion. This work has now reached a second edition, and this is a sufficient test that the work has been appreciated. We have no doubt it will have the result which is the author's highest aim, viz., of improving the management, increasing the popularity, and extending the usefulness of cottage hospitals in all parts of the world.

2. This is a very interesting paper by M. Morris, on the employment of arsenic for skin diseases, and the cases given by the author corroborate our own experience of the great value of this agent, when skillfully employed. We can commend the pamphlet to those dealing with cutaneous diseases.

3. In an Inaugural Address, delivered to the Bradford Medical Chirurgical Society, at the opening of the Session 1880-81, Dr. Rabagliati, departed from the beaten track characteristic of such addresses, and opened out a newer theme, which he has treated, not only in a learned, but logical manner. The terms in use amongst men are open to the grave

objection that they are too wide, too free in application, and too frequently used in a synonymous manner, and the object of the paper is to show that greater accuracy is necessary, especially in scientific medicine. He shows how such terms as the nature of disease, diathesis, constitution, are used and interpreted, and points out how often individual names have to do duty for general ones. After a brief survey of such names as tonic, stimulant, atonic, relaxant, astrigent, and such terms as acute and chronic, in which the writer shows his evident acquaintance with our old Greek and Latin authors, he makes this true but grave impeachment. "If you look at old writers, you will find them often mixed up, and to-day there is no definition of either in the official classification of diseases, published by the authority of the Royal College of Physicians and Surgeons of England, and adopted by the Registrar-General. As to the names of diseases, the subject is in simple and absolute chaos. We have hardly a single leading principle laid down for choosing them (unless it be that genera should be named after the part affected, and a suggestion recently made by Dr. Gowers, that diseases should no longer be named after their discoverers)." The remedy is far from being simple, for time has consecrated so many of the common terms used in medicine that it would be difficult to uproot them. It is, however, none the less the duty of the scientific physician to attempt reform, and we, therefore, welcome this communication.

4. This is a small but important paper, by the physician to the well-known hydropathic establishment at Ben Rhydding, on a disease which has hitherto been one of the *opprobria* of medicine. To the osteo-arthritis patient, life has been, in almost all severe cases, a burden. Dr. Little, in this pamphlet, the substance of which was read before the Yorkshire Branch of the British Medical Association, has adduced some striking facts to show that chronic rheumatoid arthritis need not any longer be entered in the category of incurable complaints. He conceives it to be rational, scientific, as well as successful. It does not resolve itself into the formula, come to Ben Rhydding! We have, therefore, all the more confidence in drawing attention to his method of treatment, which has the merit of practical common sense to commend it. Had we the space at our disposal, we should be happy to accord that space to a recapitulation of some of the cases put forward by the author, the pamphlet being chiefly valuable for its many clinical records. As we are unable to do this, we invite the attention of the profession to the narrative, and would ask all who have cases of this nature, to test Dr. Little's plan. It is simple, and in a disease of this nature, every rational proposal should be received with favour.

### POLLUTION OF THE SOIL BY INTERMENTS. TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a sanitary sense burial in the ground contiguous to densely-crowded populations is admitted by scientific authorities to be pernicious to the public health. When the yellow fever visited New York in 1822, the attacks of the disease were most frequent and persistent in the vicinity of Trinity Church-yard, situated in the lower part of the Broadway. It then became known that the burial-ground was overcrowded with bodies, some of which were only covered with eighteen inches of earth. Then, again, it is stated in a report of the French Academy of Medicine, that diphtheritic diseases have raged in the vicinity of such cemeteries as Père-la-Chaise, Montmartre, and Mont Parnasse, the epidemics being attributable to putrid emanations from these places. It can scarcely be questioned that, at periods of calm especially, organisms exist in the air that surrounds cemeteries, and that such organisms vitiate the atmosphere, and consequently imperil life.

For the second time a Government inquiry has been made with reference to the condition of the Battersea Cemetery. This burial-ground has a circumscribed area of but eight acres. Nevertheless, some 21,000 bodies have already been buried therein. One ratepayer stated that owing to constant illness in his family, he had been necessitated to quit the house he occupied near the cemetery, and that since he had done so, the physical condition of his family had much improved. The result of the inquiry ordered by the Home Office is unsatisfactory, so far that, although it is resolved to close the "common" ground to all interments, nevertheless, permission has been

given to still use the higher class portion of the cemetery "as long as it would last." And this conclusion has been arrived at when fever and small-pox have invaded the metropolis in so formidable a manner as to create consternation amongst official bodies.

It would, Sir, be a most desirable consummation were all the suburban cemeteries compulsorily closed. This step your contemporary, the *Lancet*, some time since suggested, and not only so, but urged upon the Home Secretary to take action in the matter. It strikes me forcibly that if the public health be considered worth preserving, or that some fearful visitation does not overtake us, we must have recourse to the earth-to-earth system of sepulture as long since recommended by Mr. Seymour Haden in his graphic letters to the *Times*. We must also cease to suffer the dead to be buried amongst the living. Woking Cemetery is, it seems to me, as to Mr. Haden, a most desirable and quiet depository for the departed. No other burial ground can compare with it, while its situation is one of the most desirable, being a proper distance from this densely-populated metropolis, daily augmenting in numbers. In this sanctuary of the dead, to use Mr. Haden's language, there are "a thousand acres of excellent land for all the purposes of a cemetery, and capable (upon the primary condition I insist upon of insuring the resolution of the body,) of effecting 100,000 interments per annum for ever, the Act of Incorporation of that cemetery providing also a separate grave for each body. The Woking Cemetery (he continues) is also the only existing cemetery in which the burial of a body can be effected with the present certainty that it will not be disturbed for ten years." The "pit" system so much in vogue is highly revolting to moral, to say nothing of Christian, sentiment. One cannot wonder that when reverence ceases to be paid to the dead that some thoughtful people should recommend cremation, in order that a step may be put to worse than heathenish practices in our mortuary arrangements.

I am, Sir, yours very truly,

MEDICUS.

British Army Medical Service.—The following is a list of surgeons on probation who were successful at both the London and Netley examinations held last week. The position in list indicates the order of merit:—

S. A. Crick	W. J. Baker	C. A. P. Mitchell
J. B. Dodd	A. T. Sloggett	G. J. Coates
A. J. Struthers	R. R. K. Elmes	G. W. H. Cook
G. E. Twiss	H. K. Allport	T. B. A. Tuckey
R. F. Adams	E. Butt	F. A. Harris
C. G. D. Mosse	S. Townsland	C. B. Lewis
A. B. Cottell	T. H. P. Woodhouse	T. H. Parke
T. Archer	J. Gibson	F. A. B. Daly
S. G. Hamilton	J. H. A. Rhodes	A. S. Rose
H. J. B. Moberly	A. Hickman	D. L. Porter
A. P. Hart	T. C. Nugent	J. Battersby
H. J. Barnes	G. S. Lewis	J. Maconachie
R. H. S. Sawyer	L. W. Swabey	A. H. Morgan
W. G. A. Bedford	R. Haselden	C. H. Dixon
R. Jennings	R. E. Ricketts-Morse	T. Moynihan
S. C. B. Robinson	W. J. B. Lyons	M. W. O'Keefe
H. S. Parker	W. Rowney	T. J. O'Donnell
T. F. W. Fogarty	T. J. R. Lucas	J. Osborn
R. W. Ford	C. J. Addison	H. E. R. Wolrige
C. J. Coultas	A. G. Kay	R. P. Hetherington
A. Sharpe	A. W. Pope	R. C. Johnston
C. L. Young	R. Porter	T. A. Dixon
C. Reid	B. C. K. Laffan	W. C. T. Poole

Indian Medical Service.—The following is a list of candidates for commissions as surgeons who were successful at both the London and Netley examinations held last week. The position indicates order of merit gained by them at both the London and Netley examinations:—

*G. M. J. Giles	H. N. V. Harington	K. C. Sanjana
A. R. W. Sedgfield	S. C. Nandi	J. W. T. Anderson
J. L. Vangeysal	G. M. E. McKee	H. M. Hakim
A. F. Ferguson	A. H. Pierson	J. A. Burton
E. F. H. Dobson	F. S. Peck	E. J. Doyle
†J. Shearer	K. H. Mistri	M. J. Kalawala
S. Hassan	W. Deane	F. H. W. Boon
R. J. Polden	P. De Conceicao	M. P. Kharegat
H. C. Banerji	G. E. Pooks	

\*Gained the Herbert Prize and the Parkes Memorial Bronze Medal.

†Gained the Maclaine Prize in Military Surgery.

Naval Medical Service.—The following is a list of candidates for commissions as surgeons who were successful at both the London and Netley examinations, held last week, in the order of merit:—

W. J. Christie	J. J. Dials	G. F. Wales	M. V. Stace
----------------	-------------	-------------	-------------

## NOTICES TO CORRESPONDENTS.

**SPECIAL NOTICE TO SUBSCRIBERS.**—The Publishers respectfully remind Subscribers that subscriptions for the past year are now due, and should be remitted for England and Colonies to the London office, for Ireland to the Dublin office, and for Scotland to the Edinburgh office.

**QUESTIONS.**—We gave a list in our issue for January 12th; your question is fully answered therein.

**A HOUSE SURGEON.**—Yes, they retire at the age of 60.

**DOWN.**—Our correspondent need only place himself in the hands of a duly qualified practitioner, his case needs no special knowledge. Before all things he must read himself from the quack Hunter; he need not fear exposure by so doing, daylight not being the particular fancy of his fraternity.

**DISPENSARY APOTHECARIES.**—A correspondent asks: 1. "Is the apothecary to one of the Dublin city dispensaries prohibited by law or otherwise from keeping, or having any connection with, a private medical establishment in another part of the city? 2. Is he obliged to reside on the dispensary premises? 3. And can he attend private patients for fees?"

[1. Certainly not, as long as he does not neglect his dispensary duty. 2. He is usually required to reside. 3. Yes, if his doing so does not interfere with duty.—Ed. M. P. & C.]

## THE CONVEYANCE OF SEA-WATER TO LONDON.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of Feb. 2nd I notice an annotation on the supply of sea-water to London. Allow me to draw the attention of your readers to the idea started by Mr. John Hayes, of 27 Leadenhall Street, which seems to possess the merits of practicability and cheapness, and that gentleman promises to be able to bring sea-water to London for less than half the price which is at present charged for it by the railway companies. Mr. Hayes's plan is to send out, attached to a tug-boat, two wrought-iron vessels of 60 feet in length and 10 feet in diameter, an air-tight, which can be filled up to a point which renders them still able to float. These are to be lashed to the side of the steamer, filled in the North Sea, and then taken up the Thames to London, when their contents can be conveyed into tanks, &c., by means of flexible tubes.

17 Woburn Place, W.C.,  
Feb. 8, 1881.

Yours obediently,  
C. R. DRYSDALE, M.D.

**MR. COLE.**—Sclerotic acid and scleromucin are active principles that have been obtained from ergot. Given together, in the proportion of gr. j. of the acid to gr. ij. of scleromucin, they act very well.

**MR. B. S. THANKS.**—Your communication, however, is more suitable for the *Students' Journal* than for the pages of the *Medical Press*.

**AUTHOR.**—The subject will be referred to in our next; it is still in a most unsatisfactory condition.

**TARPOLITE.**—This article is said to be superior to plaster of Paris, for fixative dressings, spinal supports, and the like; we have, as yet, no personal experience of it.

**A MEMBER.**—We understand that Dr. Broadbent will be elected to the Presidential chair of the Society.

**ST. GILES.**—A legally-qualified practitioner, who has passed an examination in pharmacy, not affected by the first 15 sections of the Pharmacy Act; that is, he may dispense or sell poisons, and keep open a shop as chemist and druggist. He must, however, observe the same regulations in regard to the sale of poisons as chemists.

**ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.**—This (Wednesday) evening, at 7.45, Council meeting.—8.30. Casual Communications.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—This afternoon, and on Friday, at 4, Prof. W. K. Parker, "On the Structure of the Skeleton in the Sauroptera."

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.**—Thursday, Feb. 17, at 5 p.m., Dr. J. Hughlings Jackson, "On Clinical Varieties of Hemiplegia."

**ROYAL INSTITUTION.**—Friday, Feb. 18, at 8 p.m., Sir John Lubbock, "On Fruits and Seeds."

**ROYAL INSTITUTION.**—Saturday, Feb. 19, at 3 p.m., Mr. E. S. Poole, "On Ancient Egypt."

## VACANCIES.

Brighton and Hove Lying-in Hospital.—Surgeon. Honorary. Applications to the Secretary, 76 West Street, Brighton, before March 1. Durham Union.—Medical Officer for the Southern District. Salary, £20. Applications to the Clerk of the Guardians before Feb. 18. Glasgow University.—Examinations in Medicine: 1. Physiology. 2. Clinical Medicine. 3. Clinical Surgery. Fee attached to each office, £40. Applications to Dr. Kirkwood, 145 West George Street, before March 15.

Liverpool Royal Southern Hospital.—Junior House Surgeon. Salary, £68, with board. Immediate applications to the Treasurer. Suffolk County Lunatic Asylum.—Assistant Medical Officer. Salary commencing at £100, with board. Applications to the Physician-Superintendent at the Asylum, Melton, Woodbridge.

## APPOINTMENTS.

ABBOTT, C. E., M.R.C.S.E., L.K.Q.C.P.I., Medical Officer of Health to the Braintree Union Rural Sanitary Authority.  
BATTERHAM, J. W., M.R.C.S.E., House Physician to the Royal Hospital for Diseases of the Chest, City Road, London.  
BEALY, E. O., M.A., M.B., M.R.C.P., a Physician to Out-patients at the Great Northern Hospital.  
BUTT, H. F., M.R.C.S.E., a House Surgeon to the Manchester Royal Infirmary.

CADMAN, A. W., M.R.C.S.E., a House Surgeon to the Manchester Royal Infirmary.  
CARTER, D'ARCY B., M.R.C.S.E., L.R.C.P.E.I., House Surgeon to the Clayton Hospital and Wakefield General Dispensary.  
CLARK, W. B., F.R.C.S., Surgeon to the West London Hospital, Hammermith.  
DALY, F., M.B., L.R.C.P.L., M.R.C.S.E., a House Surgeon to the Manchester Royal Infirmary.  
DUKE, A., M.D., M.R.C.S.E., Medical Officer to the Folkestone Infirmary and Dispensary.  
FROST, W. A., F.R.C.S., Assistant Ophthalmic Surgeon to St. George's Hospital.  
GRAY, J. A., M.A., M.D., M.R.C.P.E.I., a Visiting Medical Officer to the Leith Hospital, Edinburgh.  
PAYNE, H., L.R.C.P.Ed., M.R.C.S.E., a House Physician to the Manchester Royal Infirmary.  
PICKFORD, J. K., L.R.C.P.L., M.R.C.S.E., Assistant House Surgeon to the Liverpool Dispensaries.  
RICHARDSON, C. S., L.K.Q.C.P.I., L.R.C.S.Ed., Medical Officer for the Austrey District of the Tamworth Union.  
STRELL, G., M.D., M.R.C.P.L., re-appointed Resident Medical Officer to the Manchester Royal Infirmary.  
STREET, A. F., M.A., M.B., Junior Resident Medical Officer to the Hospital for Sick Children, Pond'sbury, Manchester.  
WATSON, F. S., M.R.C.S.E., Resident Obstetrical Officer to Charing Cross Hospital.  
WILKINGTON, G. H., M.R.C.S.E., a House Surgeon to the Manchester Royal Infirmary.

**ARMY AND NAVY ITEMS.**—The following were gazetted on Feb. 8th as Surgeons in her Majesty's Fleet, with seniority of Oct. 2nd, 1880:—W. J. Christie, M.B.; J. J. Dinns, M.D.; G. F. Wales, M.V. Stace.—Surgeon W. Algeo has been promoted to the rank of Staff Surgeon in her Majesty's Fleet, with seniority Feb. 7th, 1881.

## Births.

BOND.—Feb. 10, at 17 Delahay Street, St. James's Park, S.W., the wife of Thomas Bond, F.R.C.S., of a son.  
COCKROFT.—Feb. 10, at Manor Lodge, Chislehurst, Kent, the wife of T. H. Cockcroft, M.D., of a daughter.  
VISE.—Feb. 8, at Hobbach, the wife of Ambrose Blithe Vise, M.R.C.S., of a daughter.  
WESTLAND.—Feb. 10, at 16 Belize Crescent, London, N.W., the wife of Alfred Westland, M.D., of a daughter.  
WILKINS.—Jan. 18, at Trichinopoly, Madras, the wife of Surgeon T. J. Hackett Wilkins, Madras Army, of a daughter.  
WINSLOW.—Feb. 8, at Hayes Park, Middlesex, the wife of Henry F. Winslow, M.D., of a daughter.

## Marriages.

SANDWELL-LLOYD.—Feb. 9, at the Parish Church, Thurles, on Tipperary, Edward Sandwell, L.R.C.P., M.R.C.S.Eng., of Charlotte Street, Soho Square, W., to Eliza, second daughter of C. H. Lloyd, J.P., of Lisheen Castle, Templemore.

## Deaths.

AITCHISON.—Feb. 3, at 8 George Square, Edinburgh, George Aitchison, M.A., M.D., F.R.C.P.E.  
ALTY.—Feb. 8, at Birkdale, Southport, Lancashire, John Daniel Alty, M.R.C.S.E., late of Demerara, aged 69.  
CAHILL.—Feb. 6, at 26 Albert Gate, Hyde Park, London, after a protracted illness, Thomas Cahill, M.D.  
DERMOTT.—Feb. 8, at Uliceby, Lincolnshire, Pleasance, widow of Christopher Dermott, F.R.C.S., aged 76.  
HARLAND.—Feb. 9, at Tixall Lodge, Stafford, John Thomas Harland, M.D., J.P.  
HAYDEN.—Feb. 2, at Frogmore House, High Wycombe, William Henry Hayden, M.R.C.S.E., aged 68.  
OLDHAM.—Feb. 5, at West Hartlepool, B. Oldham, F.R.C.P.E.

### CLINICAL LECTURES

OR

#### INFANTILE PARALYSIS, AND ACUTE ANTERIOR POLIO-MYEELITIS IN ADULTS. (a)

By THOMAS BUZZARD, M.D., F.R.C.P.,  
Physician to the Hospital for the Paralyzed and Epileptic.

LECTURE II.

(Corrected from a Shorthand Report.)

THE patient whom I present to you illustrates an important point in the pathology of the disease, upon which as it is novel, I shall have to dwell a little.

Arthur D., æt. 17, applied here in October, 1879, on account of attacks of numbness. It seemed that for five months past he had been liable to have several times a day a feeling of numbness, which would pass all over him, but affected most the arms and hands. He had never lost consciousness. The attacks, which at first lasted but a few minutes, had become more lengthy, so that the numbness would now continue for an hour or so. He also complained of suffering from dizziness in his head, occurring sometimes along with, at other times irrespective of the numbness; and of occasional twitchings of the legs. I may say here, at once, that under the influence of bromide and belladonna these symptoms, which are of an epileptic character, have disappeared. It is not my purpose to dwell further upon them.

The point of interest to which I am anxious to draw attention on the present occasion is the condition of his face and certain of his limbs resulting from a paralytic attack which occurred in infancy. Details of the attack are not now forthcoming, but we learn that he was rapidly paralysed in the left leg, right arm, and right side of face, when he was about one year old.

If you look at his face you will see that the left angle

of the mouth is higher than the right. The right cheek looks flatter than the left, and the nasal fold on this side is absent. A like want of symmetry is not to be noted in the upper part of the face. The eyes are closed with equal facility, and he can frown with both brows. In endeavouring to show his teeth there is an absence of the natural upward movement of the right half of the upper lip. He tells us that at times food collects in the right cheek.

There is no impairment of sensation. The pupils are equal, there is no deviation of the tongue, the movements of the eyeballs, vision, taste, smell, articulation, and swallowing, are all normal. He hears somewhat better, according to his account, on the right than the left side.

Now the paralysis of the face which remains in this case looks much more like that which occurs in an ordinary hemiplegic seizure, than that which is produced by a lesion of the trunk or the nucleus of the portio dura. It is, as you see, confined to the lower half of the face, and affects especially the buccinator and those muscles of the cheek which pass more or less obliquely to the angle of the mouth. The situation indeed is precisely that which is observed in hemiplegia, but at the same time the completeness of the paralysis sixteen years after the attack is greater than that which is commonly seen in the early days of a hemiplegia. When I say commonly, I refer to the hemiplegia dependent upon lesion of the higher portions of the cerebro-spinal axis—especially the corpus striatum. You do see this amount of facial paralysis, however, where the lesion is situated in the lowest part of the pons varolii, and it is then usually accompanied by paralysis of the limbs of the opposite of the body. To this condition the term "alternate hemiplegia" is applied.

Has this been a case of alternate hemiplegia, then, from lesion of—say hæmorrhage into—the pons varolii? Let us see what is the state of the limbs. The lad stands and walks without apparent difficulty. If he attempts to run, however, he is lame, and he complains that he is always somewhat unsteady on his legs, and easily knocked over. His lower limbs are of the same length, but there is an important difference in their circumference. The right thigh, seven inches above the patella measures

(a) Delivered at the National Hospital for the Paralyzed and Epileptic.

three inches more in circumference than the left. In the calf the same amount of disparity is not seen, the left being only a quarter inch smaller than the right.

Turning now to the upper extremities, we find that the lad's grasp with the right hand is far inferior to that with the left; by the dynamometer,  $30^\circ$  as against  $48^\circ$ . The right arm is three-quarters of an inch smaller in circumference than the left; and the right forearm one inch smaller than the left. The length of the upper extremities is the same. The right deltoid is very much wasted, and in consequence of this the patient has great difficulty in raising his arm to the level of the shoulder unless he brings it in front of him, when the help of the pectoralis major is called in. In this deltoid the amount of contraction to the induced current is small. In the other muscles of the arm, and in the face, it appears to be normal; or at least not materially lessened.

Here we have, then, evidence of paralysis in the *right* side of the face, the *right* arm, and the *left* leg. This is clearly, therefore, not a case simply of alternate hemiplegia: and it is evident that the existence of one lesion will not account for the paralysis observed. On the other hand, it seems certain, from the history, that the paralysis of these various quarters took place at the same time. What is the nature of this case?

There are two points which will afford us help in arriving at a conclusion. You have observed that in the left lower extremity whereas the thigh measured three inches less than its fellow of the opposite side, the leg is only a quarter of an inch smaller than the other. The wasting of the left thigh is therefore quite out of proportion to the wasting of the left leg. Now, were this a case simply of emaciation of a hemiplegic limb from disease and impaired nutrition of muscles, there would be a strictly proportional diminution in size in the thigh and leg. In the present case it is evident that certain muscles of the thigh have wasted, whilst those of the leg have almost entirely escaped damage. If now we test the two legs, we find that the patellar tendon reflex is absent in the left, but is present in the right limb. This tendon-reflex, I may tell you, is never absent as a result of hemiplegia of cerebral origin. Its absence signifies that there is a break in the arc of nervous communication between the tendon and the muscle belonging to it. That arc includes nerve fibres going from the tendon (along with the posterior roots) into the cord, the grey matter of the cord at this level, with the large motor cells in the anterior cornu, and the anterior roots forming the motor nerve to the muscle.

It remains to be considered at what point there is a break in the arc. In tabes, as you are aware, the patellar tendon-reflex is also absent. In that disease, however, the condition of the quadriceps extensor muscle is normal. It is not (or rather need not be) wasted, and it contracts readily to voluntary impulses, to faradaic currents, and to direct percussion of the muscular substance. The motor part of the arc being thereby proved to be intact, we can readily refer the break to some point in the sensory portion, and in fact it occurs in the posterior root zone, which, as you know, is the seat of sclerosis in tabes dorsalis. But in this lad the muscular atrophy and the defective faradaic excitability, show that the lesion is on the motor side of the arc, and a consideration of the symptoms easily relegates it to the anterior cornu. This is doubtlessly wasted, and there is atrophy of large ganglionic cells.

Again, the muscles of the thigh are not atrophied in the district of a particular nerve. As you will observe, the posterior muscles supplied by the sciatic nerve are quite as much involved as those in the district of the anterior crural nerve. On the other hand, the muscles below the knee, which owe their nerve supply entirely to the great sciatic trunk, are scarcely affected. Were there a lesion of the trunk of the sciatic nerve, all the muscles supplied by it would atrophy. We must, therefore, as I have said before, go still further back for the lesion, and we

can localise it also from this point of view in the anterior cornu.

The case is evidently therefore one of anterior poliomyelitis. But how are we to explain the facial paralysis? According to my experience this is a very rare complication of infantile paralysis. Systematic works treating of the subject, either fail to mention it or expressly exclude this symptom from the category of those indicative of infantile paralysis. I have no doubt that in the case before us the facial paralysis has been caused by an extension upwards into the medulla oblongata of the process, which, when it affects only the anterior cornua of the spinal cord, occasions paralysis and wasting of the muscles of the extremities. You are aware that the medulla oblongata contains collections of grey matter which give origin to various nerves, and are homologous with the anterior cornua of the cord. In lateral sclerosis with muscular atrophy—a chronic disease—the lesion which at first causes paralysis with wasting of the extremities is apt to invade these nuclei which are contained in the medulla oblongata, and then we see paralysis of the lower part of the face, of the tongue, and the pharynx—the condition known as glosso-labio-pharyngeal paralysis. Sooner or later the adjacent nuclei of the vagus become invaded, and death is thereby caused. Now in such a case as this before us it is, I think, quite evident that the acute myelitis has invaded, along with the anterior cornua of the cord, the nucleus of the portio-dura, and produced facial paralysis.

The reason why facial paralysis is not more common in infantile paralysis I believe to be this: should the acute affection invade the bulb it is unlikely to spare the nuclei of nerves which are essential to life. It is evident that a disease which produces sudden and complete paralysis of limbs when it affects the anterior grey matter of the cord, would cause rapid death if it attacked in a similar manner the nuclei of the vagus.

And here let me say that I cannot help thinking that many cases of sudden or very rapid death which occur in children, and the cause of which is left to conjecture, may really depend upon this disease striking the medulla oblongata with the same kind of suddenness with which it ordinarily attacks the anterior grey matter of the spinal cord.

In infantile paralysis of many years standing you will sometimes find that, whereas the patient says that he is only defective in one leg, the difference between that limb and the supposed sound one is not nearly so great as you might expect. There was a young man here the other day who said that his left leg had been paralysed since he was a year old. All four limbs, he added, were paralysed at first, but the other three recovered somewhat rapidly, leaving him with this useless limb. He thought it was no shorter than the other, but we found a difference of an inch or more. Considering that the paralytic seizure had occurred when he was a year old, this was little enough—far less, indeed, than might have been anticipated, for we know that the disease often affects the growth of the bones very seriously, and it is not uncommon to find a difference of several inches between the two limbs. On coming to examine him, I found the patellar tendon reflex absent, not alone in the leg complained of, but in the other also, and, this circumstance leading to a further observation of the supposed sound leg, it was discovered that this was far from being healthy. There was but little response to faradaic currents in its muscles, which felt of a flabby and brawny character, and were evidently only less extensively degenerated than those of the left limb, which showed no response at all to either form of electric current. This explained at once the reason why there was so little difference in size between the two limbs. From what I have seen in other cases, I am disposed to think that the condition described is not at all unfrequent, indeed that it is more common than not.

There is a young man in attendance, a patient of Dr. Ormerod, who came to the hospital the other day on

account of fits, but incidentally mentioned that he had lost the use of the left leg in infancy. I have not yet examined him, but will do so now before you. (The patient was here introduced, and the lower extremities stripped.) In answer to my inquiry he says that there has been nothing whatever wrong with any limb except the left leg. You see, however, that the right leg is really not much more developed than the left, and the patellar tendon reflex is absent on that side as well as on the other. Here, again, there is no doubt the patient is suffering from the remains of infantile paralysis in his right leg as well as the left though in a somewhat less degree. It is the contrast only which has led him to suppose that the right leg was sound. Were we to test the muscles of the right limb electrically, I am sure (from the state of patellar reflex) that we should find more or less loss of faradaic excitability.

A child, Helena M.—, now attending the hospital, was brought to us on account of paralysis, which was stated by her mother to affect the right leg exclusively. She has, however, no patellar tendon reflex in either leg, and certain muscles of the left leg will not react to either electric current. It is from applying the test of the patellar tendon reflex that I have been led to discover how very generally, in a patient affected with old infantile paralysis, those limbs which were supposed to be sound are not by any means normal. I feel sure that monoplegia in this disease is far less common than it is usually thought to be, and that, as in the case which I have shown you, limbs are very frequently supposed to be sound which are in reality only comparatively so.

#### ETIOLOGY.

I do not feel able to say anything regarding the causation of this disease, except that there does appear to be a certain consensus of evidence to show that exposure to cold is a frequent antecedent, and very possibly, therefore, a cause. There is also, I think, but little doubt that injuries to the back may occasion the disease; but beyond this I have really nothing to say. From the negative side, however, there is a point which is perhaps worth a moment's attention. The disease is commonest in infants, next in children, least common in adults. Children, and especially infants, take no alcohol; the girl F— has had little or no alcohol. A typical case of the disease, B—, whom I shall show you presently, has been a total abstinence for 8 years. A single lady, set 25, affected with the paraplegic form of the disease, whom I saw lately, in consultation with Dr. Bennett, had taken no alcohol for 5 years previous to her attack. A rapidly fatal case of acute myelitis which I attended a few years ago, occurred in a man who had been a total abstinence all his life, and was the son of a total abstinence. Now I need hardly say that I do not refer to this point in order to argue that the disease occurred in consequence of abstinence from alcohol; but it is something to be able to absolve alcohol from the charge of being a probable cause of a very destructive disease. This piece of negative evidence may aid us also in other directions; that is, why I refer to it.

(To be concluded.)

### CERTAIN CONSIDERATIONS REGARDING CHOLERA AND FEVER. (a)

By SURGEON-GENERAL C. A. GORDON, M.D., C.B.,  
Honorary Physician to the Queen.

(Continued from page 151.)

**Contamination Theory.**—I apologise for giving expression to so simple and elementary a truth as that contamination by foul matters of air, earth, water, meat, or milk are, individually and collectively, causes of disease. But are they so of any one particular form of disease, specific in character, rather than of a generally deteriorated state

of body, the result of which presents itself as increased susceptibility of, or liability to, disease generally, and especially to that, whatever its form, which occurs *epidemically*? Such conditions are seldom unconnected with crowding, personal dirt, hunger, insufficient food, too often habits of dissipation, vice, crime, moral, equally with physical, deterioration. Thus, as with the one set so with the other, insanitary conditions naturally lead to, as often they are themselves results of, degeneracy, both bodily and morally. (a)

**Air.**—That air polluted by animal matters undergoing decomposition induces diarrhoea, dysentery, in extreme cases what is called putrid fever, and cholera, is within the experience of most observers and writers. That such results do not always necessarily arise from this cause is no less within their cognisance. Factories of preparations the most offensive have remained absolutely free from cholera. When in 1861 that disease more than decimated our troops at Mean Meer, so intense was the peculiar and characteristic *cholera odour* in hospital and vicinity, that it was perceptible from, and at a distance of, eighty yards; yet the propagation of the disease was not attributed to this circumstance.

If, on the one hand, instances are recorded of the occurrence of yellow fever in connection with emanations from decomposing matters on board ship in latitudes within the sphere of that disease, so instances are on record where, with a decomposing mass of *hides* on board for weeks together, the mal-odours arising therefrom have blackened the lead paint in the saloons and cabins; have produced such a degree of congestion of the mucous membrane of the nose and fauces as to persist for many months after landing; and yet although measles and boils prevailed extensively on board, there was no specific fever among the troops or crew. (b)

Here is an example of what all the large cities of China are more or less (c); and in which, reports state, that "no epidemic of febrile disease came under observation." Density of population, poverty, filthy condition of houses and streets, "it might have been presumed that enteric fever, at all events, would have come to light, seeing that the products, whence its organisms are supposed to be derived and nourished, abound in many directions." "Latrines numerous; constructed without regard to cleanliness; their contents kept for months; the neighbourhood saturated with odours of the most intense description; and yet in some private houses and restaurants in the close vicinity the people, well and lively, carrying on active and prosperous business."

Of Pekin it is stated: "We are obliged to pass certain localities at all times with closed nostrils, while hundreds of people continually live in and around and above these open cesspools, and yet manage to look well and healthy." (d)

According to an eminent writer (e) on fever in England, "it has never been demonstrated that any particular gaseous body can induce the lesions found after death from enteric fever." (f)

(a) See page 11, No. II. "New Series of Reports of the Medical Officer of the Privy Council, 1874."

(b) Such conditions existed on board the *Marlborough*, home-ward bound in 1856.

(c) "Customs Reports," No. XIII, Part 6, January-March, 1872, p. 41. Also No. 5, to 31st March, 1873, p. 41.

(d) "Customs Reports," July-September, 1872, p. 41.

(e) Dr. Harley.

(f) The following is taken from the *Globe* newspaper, and refers to Paris, namely:—"The *Havas Agency* has published a reply to the articles which have been written in the different newspapers respecting the dreadful smells that poison the air of the city. Those who suffer from the pestilential miasma are informed that, notwithstanding the manner in which their olfactory nerves are offended, the death-rate in the city has considerably diminished during the past month." The object of these remarks is to show that offensive odours are of themselves not necessarily a cause of sickness. The circumstance also is suggestive that plumbers and other persons whose work is in connection with drain-pipes, sewers, &c., do not suffer in an especial degree from fever, or from any particular form or type of fever.

(a) Read at a meeting of the Epidemiological Society of London, 2nd February, 1881.

*b. Earth.*—There is no question as to the general fact that in India the prevalence, and frequently also the occurrence, of cholera, has a distinct relation to locality, including soil and other special conditions. Localities, the soil of which is impregnated with cholera discharges, are thereby rendered absolutely dangerous as camping grounds. But the relation between cholera and the state of the soil as regards conservancy is by no means constant. From 1854 to 1867 cholera was absent from Hurdwar, the state of conservancy meantime the same; in the latter year the first regular attempt was made to improve the place in that respect, and then the disease recurred with great violence. Filthy places at Lucknow, Morar, Constantinople, Rome, &c., in 1864-5 and similarly in Central India in 1875 escaped, while others, clean and in better general condition, suffered.

Of Pekin it is said, "with all our filth, dirt, and smells, —and people in the west can form no notion of what they are, for they almost defy description—there is a wonderful immunity even from fevers." The police and scavengers are among the healthiest and most robust of our population. The beggars, a numerous class, sleep in the streets nearly all the year round; to some extent they contest with dogs for refuse of the dunghills; still they survive and flourish, and most of them look fat and sleek." (a) Similarly to my personal knowledge in Tientsin. *Hwo-luan* or sporadic, *Wan-yih*, or epidemic (b) cholera known in China since B.C. 2,500, occurred severely in Pekin as an epidemic in 1821 and 1862, and on other occasions. In the intervals local conditions were precisely as they were during the prevalence of the disease. (c)

In India the term "filth disease" has of late years been theoretically applied (d) to fevers of an *adynamic* type, or with intestinal complication, in a sense intended to explain their etiology, and preventive measures have been applied accordingly. But so far have those measures of conservancy and scavenging applied to stations been from reducing the fatality of fevers returned synonymously typhoid or enteric that, as already detailed before this Society, (e) proportionate mortality has increased very notably. Of yellow fever in New Orleans, it is stated that the city was not in a worse condition as regards dirt in 1878, while the epidemic raged, than it was in 1877, or 1876, or 1875, when there was no epidemic, and inferences were drawn on the spot which, if justified, militate against sanitation, according to the simple theory of which the nasty word *filth* is the expression.

With regard to fever my printed reports and published articles on the subject contain somewhat lengthy details, in which, by the evidence of capable observers and recorders, outbreaks of fever presenting characters such as are held to distinguished typhoid or enteric have occurred on virgin soil, where contamination by filth or other organic matter was simply impossible. Among such places are enumerated Natal, New Zealand, Cyprus, Ascension, &c. Even in localities and on occasions when either or all the diseases named coexist with "insanitary" conditions, it is well to demarcate between such coincidences and the relation necessarily connecting effect with cause.

On this subject of local contamination, a well known professor and writer (f) on Public Health observes that "all who are deeply interested in sanitary reform are to imbibe an unconscious predilection for the doctrine that all diseases which prevail epidemically are the offspring of filth and overcrowding. This extreme doctrine is rejected by all the best authorities." He then discusses the subjects of contagion and epidemic influences or constitution,

furnishing the explanation of phenomena which the theory of local contamination alone fails to demonstrate. A still later writer (a) takes up the latter subject, and I should have wished to present their views. They can now, however, be no more than thus alluded to; my limits altogether preclude me from following them. (b)

*c. Water.*—The capacity of water to convey the disease cholera under certain circumstances is acknowledged. Not so the precise manner in which this takes place, nor the precise nature of the thing conveyed, whether germ, (c) poison, or *morbific influence*. According to the International Commissioners, doubts are expressed as to water thus contaminated being rendered innocuous by either filtration or boiling; (d) chemistry also fails to detect the existence of contaminating material of specific kind. But there are many instances on record where cholera has spread in localities where contamination of water was impossible: also of two sets of troops using water from the same source, the one set being attacked by cholera, the other set remaining absolutely exempt. Contaminated water induces also other diseases than cholera, more especially diarrhoea and dysentery. It does not of necessity induce cholera, even in places where that disease is endemic, epidemic, or both. In those where it is neither endemic nor epidemic at the time, water, however contaminated, does not induce it. (e) Many German authorities are opposed to the theory of choleraic water poisoning on the grounds that it failed to account for the diffusion of the epidemic in Munich, Bavaria, Saxony, Baden, and villages around Vienna. (f)

To quote one of the most recent writers on this subject (g)—"Did we find outbreaks of cholera uniformly occurring at those seasons of the year when the drinking water of the community is most foul we should with reason connect the phenomena. But it is not so. Thus, in Bengal, cholera is on the increase in October and November, when the drinking water is about its best; and the spring outbreaks occur towards the end of February or beginning of March, at a time when the water of rivers, tanks, and wells is as yet unpolluted by the rain washings of accumulated dirt from the surrounding surface."

With regard to fever in India, there is a concurrence of opinion that in *malarial* localities attacks of malarial fever may be, and are, induced by means of water in such places contaminated with decomposing vegetable matters. As explained at considerable length in my reports and printed articles on the subject, cases of malarial fever become in their progress complicated with infiltration or ulceration of the glands of the ileum, as with other forms of organic lesion; the phenomena of the disease in particular individuals and stages of attack assume a low, *adynamic*, typhous, or typhoid character. In this sense there appears to be no doubt as to the influence of contaminated water in the causation of fever. But, as a matter of fact, of 175 cases, details of which are given in my first special report, and

(a) Dr. Guy, "Public Health," p. 38.

(b) J. Parkin; see *Journal of Science*, Nov., 1880, p. 715.

(c) In 1870 Prof. Cohn described a peculiar microphyte, *Crenotheca polypora*, which he found in the well water of a certain district in Breslau famous for the frequent occurrence of enteric fever among its inhabitants.

(d) Dr. Parkes stated that "it is uncertain how far boiling will destroy the poison of specific diseases. Purification of river water for drinking by means of boiling was practised in the armies of ancient Persia B.C. 550."

(e) On this subject Dr. Parkes said, "although the origin of typhoid merely from putrefying non-typhoid sewage is not at present considered to be *probable* it is not *disproved*."

(f) At Newcastle in 1854, and in reference to the now famous Broad Street pump case, it was not until cholera had become epidemic in England that contaminated water induced an attack of the disease.

(g) Dr. Somerville observes in his "Report on the Health State of Fochow," for the half-year ending 30th Sept., 1875—"I think there is a growing opinion in the profession, especially entertained by those who have had much experience in tropical and sub-tropical countries, that water containing organic matter has been too heavily blamed as a cause of disease."—See "Customs Reports," No. XXVII., July-September, 1875, p. 48.

(b) "Customs Reports," July-September, 1873, p. 41.

(c) See p. 39.

(d) "Med. Reports, Privy Council," No. V., for 1873, p. 9.

(e) "Notes on Fevers," p. 1.

(f) Mr. James Ball writes thus in the *Journal of the Society of Arts*, January 21st, 1881:—"Professors of sanitary matters are so utterly at variance upon what they individually consider to be vital questions, that the public could not place anything like implicit reliance upon the reports furnished them."

10 additional contained in my second, in but one instance was a connection established between an attack of fever and the water made use of by the subject of attack.

Here is an illustrative instance of what is looked upon as water causation recently adduced in India. At a particular station (a) 28 cases of fever occurred among soldiers; of these, 24 in a body of teetotallers, who were quartered in various localities in that station. The men of abstinence were wont to assemble at their place of meeting, and there, in the words of the reporter, make merry on their beverage drawn from a pump hard by, the pump unused by other men in the cantonment. And so, at the risk of causing alarm to the class referred to, the cause of illness was assigned to the cause of water only, all other circumstances and conditions affecting the men in question being passed over silently. But what of the cases to which this cause could not be assigned? What of other men of the class alluded to, their number left unstated, who had no fever. That persons whose social condition, habits, and mode of life present similarity should be subject to prevailing disease of allied or similar type is but in accordance with analogy. That the class here indicated is more likely to suffer from fever, asthenic in type, than from ardent or inflammatory, is in accordance with observation. (b) But as a development of the theory of single and it, water causation here alluded to, I remark that interesting statistics are wanting as to comparative coincidences between cases of fever and particular sources of water supply in affected localities, and coincidences between fever attacks and supplies from butchers, bakers, grocers, or other establishments in the same localities. In India, all these sources of supply are equally under strict supervision. Also, has the oxidising power of water upon the decomposing organic matters recognised only a few years ago been now clean forgotten? Do any of my contemporaries recollect their experiences of outward bound voyages in sailing ships ere the first half of this century had yet been reckoned of the past? Do they recollect how the water casks in those days had the reputation of being filled from the Thames at Blackwall while the tide was low; that afterwards while the process of what was called "settling itself" was in progress, foul odours of sulphuretted hydrogen rose with violence from the casks; then after an interval this "settled" water became sweet and palatable? And do they also recollect the wonderful measure of health enjoyed on board such vessels, no fever, no bowel disease of any consequence, no deaths among a strength numbering close upon 200, during a voyage ranging in length from four to six months, their numbers greater when disembarked than when embarked, by reason of births on board.

This is the state of the water supply at Canton, as described not long since (c):—The creek San-t'sung is not far from the foreign settlement; it is narrow and covered with boats; on either side of it are innumerable houses, chiefly brothels; the alvine dejections and other impurities of thousands of inhabitants along it are daily discharged into the stream; yet the water, too dirty even for washing, is daily used for culinary purposes without being filtered or precipitated with alum as is done in Shanghai. (d) Here we should expect the prevalence of

(a) Kamptea.

(b) Compare this with the remarks already quoted from Surgeon-Major Don regarding the classes most liable to asthenic fevers in Bermuda.

(c) "Chinese Customs Report," No. 13, part 6, January to March, 1872, p. 21.

(d) "At Shanghai, the creeks receive drainage from the manured fields, and in them the natives regularly scour their ordure buckets. From such a source is the water supply for foreigners obtained."—"Customs Reports," July-September, 1873, p. 55. It is true that the Chinese, as a class, drink only water that has been boiled, or in which tea has been infused, and that their relative exemption from cholera has been attributed to this circumstance.—See references already made to the assumed resistance of theoretical specific poisons to the process of boiling.—In all shapes such causes of *pythogenic* fever, as are usually assigned exist abundantly in Chinese towns, yet only isolated and rare cases presenting characters of that disease are reported among the dense population, nor has this form apparently as yet spread as

such diseases as typhoid fever and diarrhoea occurring often enough to attract attention; but, according to the observer (a) from whom I quote, the people who use this water are not more subject to fevers and other diseases than their neighbours, and this impunity is one of the reasons for their continuance in the use of such water. The writer quoted remarks in reference to this circumstance: "A detailed examination of this creek and the disgusting habits of the inhabitants would almost unsettle one's idea of the connection between typhoid fever and polluted water." At Foochow, (b) conditions are described as equally bad in this respect as at Canton, and the same may be said of many other Chinese towns and cities, and yet there is no enteric fever in them, and for the most part cholera, when it does occur, is by accounts less fatal than it is in India or in Europe. (c)

(To be continued.)

#### A RECORD OF CASES TREATED ANTISEPTICALLY, AND OF CASES ACCORDING TO LISTER'S METHOD, WITH REFERENCE TO CASES TREATED WITHOUT ANTISEPTICS, AND REMARKS. (d)

By W. J. WHEELER, M.D. & M.S. of Dublin University, Fellow and Member of Council of the Royal College of Surgeons; Surgeon and Lecturer on Clinical and Operative Surgery to the City of Dublin Hospital.

For some years I have given much attention to the most efficient method of dressing wounds, and those inflicted after operation, believing that the best means of arriving at a reliable conclusion was by comparison. I adopted this plan, taking the history of each case, and accurately noting all points worthy of interest. I am now enabled to give an epitome this evening of some cases treated after two definite and distinct methods. One I would style Antiseptic Surgery, the other Listerism. The results I bring before this Society must necessarily be limited—firstly, because time would not permit me to enumerate anything like the numbers I compared, and, secondly, because I have selected cases as nearly approaching to one another as possible, in order that comparison may be more interesting.

an epidemic. It were strange if among the many characters assumed by the general disease fever, particular lesions in the intestines, as of other organs, did not occasionally happen. There is, however, nothing in that circumstance to indicate that in their nature or causation they differed from those, the complications of which affected other organs and tissues."—Dr. Gardener quoted in first special report, p. 11. At page 21 of the *Chinese Customs Gazette*, January-March, 1872, the following occurs in reference to typhoid fever: "Since the sewage question has been so much in agitation in connection with this fever, it may be well to mention that in Canton large numbers of the native population are daily using water and inhaling air charged with the impurities of human excreta apparently with utter impunity. River water is greatly used, but that used by the crowded boat population along the different jetties is extremely filthy. The Sampan people prefer to get it by the side of their own boats, simply because they receive no harm by the practice." Nothing appears to indicate other than that among the boat population of Canton, water is used in the ordinary way, that is, boiled for culinary purposes, *unboiled* for other purposes. This significant remark occurs, however, at the place quoted: "The natives have no faith in the skill of foreign physicians in the cure of fever, and when taken with it they do not send for them, nor do they come to the hospital to be treated as in-door patients. From native books and physicians we can gather no distinct idea of such a disease as typhoid fever" among the Chinese.

(a) Dr. F. Wong.

(b) "Customs Reports, January to March, 1873, p. 41.

(c) A similar state of things is described as existing in Japan. There, as in China, the fields and growing vegetables are at short intervals of time drenched with liquid human filth; the canals and water courses are contaminated by water which escapes from the fields, and yet no special disease among the population is assigned to this cause.—See *Journal d'Hygiene*, No. 228, of 3rd February, 1881.

(d) Read before the Surgical Society of Ireland.

By the first method I understand absolute cleanliness, adequate drainage, and complete rest, the second method I will designate that of the Carbolic Spray and Gauze. By adequate drainage I mean that free escape from the wound of either blood, serum, or pus, as the case may be. By rest, I mean it in its physiological sense, not merely absence of movement, but such want of rest, for example, as might be caused by the application of an irritant or unescaped discharge, causing pressure on nerve filaments. I shall now relate short details of some cases treated antiseptically:—

1. Disease of knee-joint. Man, aged 23 years; history, injury, ending in synovitis; constitution healthy; family history good; pulse, 84 per minute; temperature, 99·2 deg. night before operation. Amputated in lower third of thigh by rectangular flap; torsion used, with vessels washed with chloride of zinc solution. Evening temperature on day of operation, 100·8 deg.; pulse, 104. Edges of wound brought together by means of silver wire. Wound healed in thirteen days, except right or inner angle; this was healed on the eighteenth day; the highest temperature, 101 deg.; discharge, sero-sanguineous for thirteen days, when a few drops of pus could be seen at the unhealed angle for five days. This may have been caused by a silver suture which had remained in angle of wound through an oversight.

2. Disease of knee-joint and lower third of femur.—Young girl, aged 18 years, much emaciated; had night perspirations, jerking and spasms of limb; temperature varying from 99·4 deg. to 101·3; family history bad; she being youngest of seven children, two only alive. Amputated at middle third by circular method; solution of chloride of zinc brushed over stump; drainage and rest carried out as in preceding case; vessels twisted, except femoral, which was tied with catgut. Temperature, night of operation, 102 deg.; pulse, 130 per minute; highest temperature, 103 deg., subsiding after fifth day to 99 deg.; discharge, sero-sanguineous; became slightly purulent after fifteen days; healed at the twenty-ninth day.

3. Boy, aged 14 years; disease of knee-joint and shaft of tibia, originating in injury; family history good; two openings, sinuses, leading into joint on external aspect; temperature and pulse normal the day before operation. Operated above condyles by Luke's method; washed with chloride of zinc solution, 10grs. ℥i; vessels secured with catgut. Temperature, night of operation, 99·4 deg.; highest temperature after operation, 100 deg.; highest pulse, 102 per minute; healed in eighteen days. The discharge could not be called purulent at any time; drainage as in other cases.

4. Woman, 36 years; disease of knee-joint not admitting of excision, originating from a fall some years before; pulse and temperature normal. Amputated in lower third by rectangular flap; vessels secured by torsion, except the femoral, by catgut ligature; highest temperature, 99·8 deg.; washed with carbolic lotion (1 in 40); placed on splint; drainage by four threads of silk soaked in carbolic oil; discharge never purulent; healed in eleven days; flaps brought together with silver wire.

5. Woman, 38 years of age; extensive disease of right knee-joint and abscess of tibia in head of this bone; suffering for three years; temperature, 99 deg. Amputated by means of rectangular flap at lower third of femur; drainage tube from one angle to other flap brought together by means of silver wire; highest temperature, 99·8 deg.; highest pulse, 104 per minute. There was not any constitutional disturbance. Carbolic lotion used as dressing; stump placed on splint, and healed in eighteen days; vessels were secured by torsion, except femoral artery, which had catgut ligature applied to it; a few drops of pus for the last two days at inner angle.

6. Disease of the knee-joint. Girl, 9 years of age, much emaciated; had night sweats; pulse, 120; temperature, 101·4 deg.; appetite, capricious; great pain evinced on pressure; five sinuses round joint; discharging. Amputated at lower third by circular method; vessels secured—fourteen in number—by catgut; sinuses freshened and

brought together by catgut suture, flaps by silver wire; highest temperature, 102·3 deg.; highest pulse, 120; healed in thirty days; chloride of zinc solution (1 in 20) for dressing; limb placed, as in other cases, on splint; discharge for nine days, sero-sanguineous, afterwards purulent.

7. Boy, 16 years; removal of foot, by Symes's operation, for disease excited by old injury, a horse standing on him; temperature day before operation, 98·4; pulse, 84; plantar arteries secured by catgut ligature; small vessels twisted; drainage tube passed through posteriorly; temperature day after operation, 99 deg.; highest temperature, 99 deg.; discharge, sero-sanguineous, never purulent; washed with chloride of zinc, ten grains to the ounce; entirely healed in fifteen days.

8. Removal of foot, by Chopart's operation, from boy, aged 11 years. Middle cuneiform bone appears to have been the primary seat of the disease (caries); three openings (sinuses) could be observed corresponding to cuboid middle cuneiform and third metatarsal bones; temperature day before operation, 99·8 deg.; highest temperature after operation, 100·1 deg.; washed with a solution of salicylic acid; vessels secured with catgut; healed all but one of the small openings, where drainage tube was, in twelve days; completely healed in seventeen days; for last four days a very small discharge, about half a drachm, which was slightly purulent.

9. Excision of elbow, in the person of a young countryman, aged 33 years, for disease not extensive; temperature day before operation, 99·8 deg.; highest after operation, 101·2; pulse, 120; vessels tied with catgut; drainage tube ran from one end of incision to the other; washed with chloride of zinc solution; wound healed in twelve days; very little discharge, which was chiefly serous, not purulent; final result, all that could be desired.

10. Boy, 8½ years old, with disease of elbow-joint; thin and emaciated; openings leading to bone at posterior part of joint; highest temperature after operation, 102·8; highest pulse, 130; drainage tube used as in preceding cases; discharge not excessive, but purulent throughout; completely healed in twenty days; result, excellent.

11. Healthy woman, having a large fatty tumour, which weighed, directly after removal, 3 lbs. weight, situated at the back of left shoulder; pulse and temperature normal; temperature after operation, 98·8; pulse, 96; drainage tube inserted; wound adjusted with silver wire; washed with chloride of zinc (20 grs. ℥j); discharge, serous; healed completely in eight days.

12. Young woman, aged 30 years, fatty tumour on lower part of back, which weighed nearly two pounds weight; incision to remove it was about five inches long; no appreciable discharge; small drainage tube removed on second day; entirely healed on fourth day; washed with water. Highest temperature, 99 deg.

13. Male, 26 years, suffering from malignant tumour of left thigh, about middle third over fascia lata, about the size of a large orange; temperature at night, 99·2 deg. before operation; highest temperature after operation, 100·8 deg.; drainage tube used, &c.; washed with chloride of zinc (20 gr. ℥j.) lotion, brought together with soap plaster and a few points of silver suture; discharge for eight days serous, and red from that till the twelfth day, when he was healed what may be called puriform, for want of a better name.

14. Male, 32 years old; amputation of forearm for gunshot wound of hand, which was nearly torn off limb; well washed with carbolic lotion (1 in 40); operation performed; modified circular vessels secured with cat gut, three threads of silk soaked in carbolic oil, placed across wound, acted for drainage; highest temperature, 100·4 deg.; completely healed in fourteen days; discharge serous; a few drops of pus observable eleven days after operation.

15. Male, aged 55 years, received an extensive wound, five and a half inches in length of left knee joint, from a fall; extending obliquely across joint. I happened to see him directly on admission to hospital. Cleaned wound with zinc solution; drew parts together; applied splint on

posterior surface of limb; zinc lotion applied over it, and an ice bag; two ligatures of catgut left in for drainage across wound; highest temperature, 100.1 deg.; made a good recovery. I saw him lately attending the ophthalmic hospital with the motion of his joint unimpaired; discharge, partly synovial fluid, serum, and blood.

16. Male, 42 years, with little febrile disturbance, suffering from a purulent collection in right knee joint, which was evacuated by free incision; joint washed out with carbolic lotion (1 in 40 diluted) by means of Richardson's hand spray; edges of wound brought together save where drainage tube was inserted; small piece of sequestrum came away on fifth day; limb steadied by splint at back; highest temperature, 101 deg. Man made a good recovery and has considerable motion in joint; discharge serous, mixed with small quantity of purulent matter.

17. Excision of hip joint. Male, 13 years; for disease of head of femur brim of acetabulum being eroded; five sinuses led to diseased bone; the temperature before operation was not ascertained; highest temperature after operation, 102 deg.; washed with carbolic lotion (1 in 40); drainage tube employed; discharge, sero sanguineous for four days, afterwards the same, mixed with purulent matter; was healed in two months.

18. Female, 39 years; excision of breast for scirrhus cancer; three glands could be felt enlarged in axilla freely movable; washed with chloride of zinc solution; vessels, some twisted, others ligatured with catgut; brought together with silver wire and straps of adhesive plaster; drainage tube used; discharge never purulent; was healed within ten days; highest temperature, 99.8 deg. I could relate several very similar cases, the mean highest temperature being 99.9 deg., and the mean time for complete healing thirteen and a-half days.

19. Boy, 9 years, much emaciated, had two bed sores when admitted to hospital suffering from disease of left foot; operation rectangular; flap vessels tied with catgut ligature, brought flaps together with silver suture; drainage accomplished by catgut ligature passed across; wound dressed with chloride of zinc lotion and carbolic oil; discharge never purulent. Dr. Kidd and Dr. Barton saw the case; highest temperature, 101 deg.; healed in fourteen days.

EPITOME OF CASES TREATED BY "LISTERISM."

1. Male, 28 years, by circular method; amputation of thigh in middle third for necrosis of femur, which had disorganised joint before admission; family history not good; pulse and temperature before operation slightly accelerated; vessels secured with catgut, and stump treated in accordance with prescribed rules; highest temperature, 101.2 deg.; discharge, sero sanguineous, slightly purulent the last few days; healed on twenty-first day.

2. Male, 30. Amputated at middle third of femur for disease, by rectangular flap; family history bad, mother and two sisters and a brother died of phthisis; says he had lost at least 11 lbs. weight in three months, no lung complication; highest temperature after operation, 104.2 deg., pulse over 130 per minute, free suppuration; healed on the twenty-seventh day completely.

3. Young girl, 15 years, amputated for disease of bones of leg and femur at lower third, by flap operation; temperature before operation, 98.8 deg., pulse normal; not emaciated, no night perspiration; highest temperature after operation, 100.3 deg.; discharge never purulent; healed on sixteenth day.

4. Female, aged 36 years, treated at the same time and in the same ward, is the fourth case I recorded of amputation by the rectangular flap method for extensive disease of her joint and femur in the lower third; her temperature was 99 deg. the day before operation, the highest temperature after operation was 100.5 deg.; the discharge was purulent from the commencement; she did not heal completely for twenty-seven days.

5. Female, 18 years, of ruddy complexion and healthy appearance, was admitted suffering from fluid in the right knee joint, which was determined to be pus; was evacu-

ated by free incision, and carefully treated according to Lister's method; joint well washed out with carbolic acid; drainage tube inserted, &c.; highest temperature after operation, 100 deg.; discharge partially purulent for a day or two, then changed and became serous; patient made an excellent recovery.

6. Female, 13 years, suffering from disease of the foot; Syme's amputation performed; highest temperature after operation, 105 deg.; suppuration profuse; urine dark coloured and scanty; some sickness of stomach; gauze removed; water dressings and oil silk applied over stump; region of loins dry cupped; suppuration decreased, urine increased in quantity, and lost its dark colour. The girl made a good recovery, and has an excellent stump; thirty-seven days healing.

7. Excision of elbow in young woman, 27 years, for disease of humerus and ulna; temperature before operation, normal, highest temperature after, 101 deg.; healed without any purulent discharge in fourteen days. Result excellent.

8. Excision of elbow joint. Boy, 14 years, diseased elbow joint, one sinus leading to bone; highest temperature after operation, 102 deg., highest pulse, 134; discharge purulent; healed in twenty-five days.

9. Male, aged 41, having a fibro cellular tumour growing from right side, which weighed on removal 4½ lbs.; incision required to remove it; about eight inches long; highest temperature after operation, 98.6 deg., highest pulse, 84; discharge very purulent; healed in eleven days.

10. Male, 49 years, fatty tumour of left gluteal region, weighing on removal 3 lb. weight; length of incision about seven inches; healed in seven days; highest temperature, 99.1 deg.; discharge sero sanguineous.

11. Female, 42 years, excision of breast for scirrhus cancer; one gland could be felt enlarged in axilla; highest temperature after operation, 100 deg.; was healed in seven days; discharge not purulent.

12. Excision of hip joint. Male, 19 years, for disease of head and neck of femur; three sinuses lead to the diseased bone; this patient was much emaciated; temperature before operation, 100 deg., highest after operation, 103 deg.; discharge serous and afterwards purulent; left hospital after two months nearly healed; there was then a small opening which was discharging, it finally closed.

13. Boy, 12 years of age, right knee joint much distended and full of pus; limb placed on splint and freely opened; washed with carbolic acid and dressed; severe febrile symptoms followed; temperature ran up to 105.2, pulse more than 130; dressing removed; flannel wrung out of hot water, covered with oil silk, placed round joint, &c.; it finally had to be amputated. He recovered slowly.

I have thus given a detailed account of as many cases as the time prescribed by the rules of this Society would enable me, with my further remarks, to make. I think it will be obvious that the more serious, or severe cases, were not chosen for one method more than the other. I have carefully avoided alluding to operations about the mouth and face, as excisions of upper and lower jaws, &c., &c., "Listerism" being inapplicable. I have not alluded to ovariectomy, as it will be more profitable to review the opinions and statistics of those who have necessarily much more opportunities than I could possibly have. I have omitted excision of the knee, as I only tested one case by Listerism for the same reason as compound fracture. I have treated psoas abscess by both ways, with excellent results, and only allude to them here to condemn the aspirator. On review of the cases I have quoted, I find that the mean highest temperature of those treated antiseptically is, in nineteen cases, a little more than 101°, against thirteen treated by Listerism, which show a mean highest temperature of a little more than 102.2°; that in one of the cases quoted, the Listerism had to be stopped on account of signs of carbolic poisoning; that a wounded knee-joint healed without Listerism, and that others, opened to evacuate pus, progressed favour-

ably. In many cases that I have employed Listerism, I have found suppuration increased by the continuance of carbolic acid, of the strength recommended, and eczematous rash, produced by the gauze, in several cases dark-coloured urine, it being also scanty. The patients, on many occasions, complained of uncomfortable heat in the part covered with Lister's dressing.

Now the cases I have detailed were hospital cases, but I cannot let pass one case I operated on in private, it was a varicocele of left side. I cut down on large veins, ligatured them with catgut, washed the part with chloride of zinc, put in a drainage tube, the gentleman healed without a bad symptom; had the spray been used in this case by a Listerite, the system would have been extolled to the skies. I cannot help also alluding to nine excisions of the breast I saw performed by Mr. Butcher, in his private practice last year. Six of these I happened to see on three occasions, had almost healed by first intention, yet they were not treated by Listerism, but antiseptically; had the case of wounded knee-joint been sprayed, had the other that was incised to evacuate matter been sprayed, and treated with this elaboration of Lister, the credit would have been given to that system; had the cases that I mentioned, which healed without suppuration, been treated by the spray, &c., it would have been stated for an undoubted fact, that such a result could not have been otherwise accomplished.

Professor Lister does not claim absence of pus for the method called his, yet we have partizans of his system, even amongst ourselves, asserting this, through what the *Lancet* has termed ignorance and folly (*vide* 25, 12, 80).

The heading of my paper refers to cases treated by the old method. I make mention of it at all, merely because it has been insanely attempted to draw a comparison between treatment of wounds in bygone days, and treatment in the present day, and to attribute all improvement to Listerism, where we all know that there was not that strict attention to cleanliness nor drainage. Well do I remember an honoured and learned preceptor strapping a stump up tightly and closely with adhesive plaster after operation. Explaining how pressure would stop the oozing, and in three or four days, when the plaster was being removed, would ask what was the cause of its being blackened, the sulphuretted hydrogen of the pus. This was a man who attended strictly to the hygienic conditions of an hospital, and was well-known in this College as an accomplished and erudite lecturer. There are many, for the most part, partizans, who guided by authority, and not by their own clinical research, attempt to ridicule and criticise the honest inquiries of those who wish to understand something of the theory on which this elaborate system of Lister is attempted to be founded. I regret to say that in a paper read before this College, and published in March, 1880, the writer foolishly adopts this course, for it is quite evident to anyone of education that he confounds two theories—contagium vivum, and the germ theory, indeed, he appears to know nothing of the former, and thus leaves those whom he would wish to rebuke an opportunity to sneer. If I understand Lister's theory, he accepts Pasteur's views, that there are germs in the air which cause putrefaction on their admission to wounds, and that these develop, *ad infinitum*, whenever they meet a suitable medium, and that by spraying the air with carbolic acid of prescribed strength, he washes it of these impurities, and prevents their deleterious effects. This theory I cannot hold to be tenable, unless it can be answered to me satisfactorily, as already asked by others.

1. How is it that a person can be self-poisoned without an external wound at all, by a deep abscess, not in contact with the air?

2. And how can the opposite condition exist, internal abscess, impregnated with *bacteria*, and yet no blood-poisoning?

3. How I would ask, is it that a ruptured perinæum will unite immediately, when we are told that all these mucous canals abound in bacteria?

<sup>1</sup> How is it that the same forms of cocco-bacteria are

just as frequently found in the secretions of wounds, treated after Lister's plan, said to be without constitutional disturbance, and to have a brilliant result, as in the secretions of wounds treated by the most ordinary methods.

The inference is Lister's method is no guarantee for the destruction of the bacteria, and that the presence of these germs, in the discharge of wounds, does not account for their poisonous properties; perhaps they are taken into the blood by the inspired air, and that, under healthy conditions, they do not develop, but may in the discharge of a wound.

If this is possible, Lister's method, chemically dealing with germs, is not tenable, and falls to the ground. Add to this the evidence given by Dr. Bantock, in the *British Medical Journal* of January 8th, 1881, that fluid, consisting of blood and serum, obtained from three drainage cases, in which the operation was performed with the one per cent. solution, that these fluids, varying from one week to six, were free from all appearance of decomposition, and that in each of these cases the tubes were exposed to ordinary air on many occasions, and the spray was not once used.

#### STATISTICS.

Much has been said about favourable statistics from the use of Listerism, and those of Prof. Nussbaum have been dwelt on; but any one who looks closely into the facts connected with his statistics will find, to use the words of Mr. Thomas Smith, that his hospital was a veritable pest house—erysipelas, pyæmia. Gangrene being almost always prevalent, any cleanliness would therefore cause improvement. And the Professor boasts that since his adoption of Listerism, he has not had a case of amputation attacked by gangrene. If such is to be boasted of, I can assert I have never had gangrene following any amputation of mine, although in passing, I may remark that a case of amputation by the rectangular flap method lately came to my knowledge, which was dressed with all the elaboration of Listerism, yet became gangrenous. If, however, we look at the statistics of Mr. Spence, of St. Bartholomew's Hospital, we find others not practising Listerism. The statistics are equal in result to those obtained by diagram; and recently those published by McVail (of Kilmarnock) are superior to any brought forward by the disciple of Lister. But turning to ovariectomy, the great standpoint of the Listerites, I find the following, quoted from the proceedings of the Royal Medical Chirurgical Society of December last year: "Mr. Spencer Wells said that the mortality in his practice had certainly diminished as his experience had increased, and since adopting the antiseptic method (meaning Listerism) in 1878 he had 131 cases with 13 deaths, or 10 per cent., the death rate being exactly the same as in the last two years of hospital practice without special antiseptic measures."

There is no doubt that Mr. Spencer Wells has improved his statistics by experience. As a proof, we have been condemning in the most emphatic way the use of the ligature as applied to the pedicle, saying "the more I am driven to resort to the cautery or the ligature, the less I am satisfied with the results of this method, the more reluctant I am to employ them, and the greater is my confidence in the clamp." Mr. Wells does not corroborate the statement by his practice now. In a treatise on ovariectomy dedicated to the late Dr. J. Beatty by Mr. Butcher, I find the ligature adopted, and one of the patients operated on in the theatre of his hospital with excellent results. Yet we are told by the followers of Prof. Lister that he was the first to show that ovariectomy might be performed in a theatre. I find Mr. Holmes stating at the meeting already referred to, "that the statistics brought forward showed no decided difference in favour of Lister's method in ovariectomy. Add to this the results of Dr. Bantock, that in proportion as he reduced the strength of the spray solutions and those for cleansing purposes, in proportion did pyrexia diminish after his operations. We have also the same evidence of Dr. Tait and Dr. Savage, the latter an advocate

of Lister's method; there is an erroneous impression that there is a general concession to the adoption of Listerism. In addition to what I have already read, I could add the name of Mr. Bryant, who expresses his disappointment and surprise when he found it asserted that "loose cartilages may now be removed by direct incision from the bone without any apprehension of evil results," was based upon the experience of *three* cases, and is disposed to think that an equally good series of cases might be extracted from the ordinary case book of the hospital surgeon. Mr. Hutchinson says he speaks on the general question with diffidence, and asks, how is it if the spray and gauze plan of dressing be so valuable, that some of those who do not use it get such excellent results? At the London Hospital Lister's precautions have been most ably carried out by one of his colleagues; yet his mortality has never been lower than Mr. Hutchinson's, and he (Mr. Hutchinson) thinks an exaggerated impression as to the injurious effects of common air has got about, and believes it possible that the spray and the gauze plan may cause harm in some cases. Nor does he think it applicable to compound fracture, nor a help where it is important to avoid a conspicuous scar. That other means are to be preferred for wounds already exposed to risk of infection, and in cases where inflammatory conditions have already set in.

Sir James Paget attributes the improvement, amongst other reasons, to the leaving off of some of the bad practices of surgeons, such as bleeding before operations, and the use of active aperients and antimony, &c., and to the improvement in the sanitary conditions of our hospitals. It has been argued that if some of the staff in an hospital use the spray, that it confers a benefit on the cases of those who do not use it.

This cannot be said of many of mine brought before you this evening for comparison, as they have been selected for the most part from cases treated before the steam spray was purchased for the hospital by Dr. Henry Fitzgibbon, to whom alone its permanent introduction with the gauze is due—I say permanent, for prior to that time I had used the steam spray, getting it from Messrs. Fannin, of Grafton Street.

Not wishing to be led by mere authority, I made a comparison of cases; a few of them I have brought forward to-night, believing such procedure interesting. I am not a believer in the spray and gauze, but I do believe in that system which I have termed antiseptic surgery.

I cannot, however, close this communication without paying tribute to the man who re-introduced animal ligature, and assisted to harmonise rest of wounds first forcibly advocated by Hilton, with the drainage first recommended by Callender and Heath; and thus draw our attention more prominently than heretofore to absolute cleanliness.

## Clinical Records.

### CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

Under the care of Dr. BIRKETT.

*A Case of Phthisis—Hæmoptysis—Recovery.*

Communicated by SIDNEY DAVIES, B.A., Clinical Assistant.

THOMAS CASSIDY, æt. 40, tailor, was admitted into the City of London Hospital for Diseases of the Chest on Oct. 5th, 1880. He was a short, dark man, and gave the following account of himself.—He had enjoyed good health until May 10th, 1880, when his present illness began with catching cold; he began to cough and to spit blood, which he stated sometimes amounted to a pint and a-half at a time. The hæmoptysis ceased after two weeks. Subsequently he suffered from night sweats, and lost flesh. The night sweats had diminished of late. The hæmoptysis had recurred a week before admission.

On admission the patient was anæmic, and thinly covered with flesh. The fingers were clubbed. Tongue slightly

coated; bowels irregular; appetite fair. He had a bad cough, with copious sputa, unmixed with blood. His voice was very hoarse. His breath was offensive. Pulse 108; evening temperature 100·8 deg.; morning temperature 98 deg., urine acid, sp. gr. 1020, containing no albumen.

Dr. Birkett made a physical examination of the chest the day after admission. The signs were as follows:—*In front*—right side, respiratory movements diminished; no bulging of intercostal spaces; dulness at the apex, accompanied by loud bronchial breathing; crepitation on coughing, and bronchophony. Left side: Respiratory murmur heard over præcordial region; heart sounds distant; inspiration loud. *Behind*—Right side: Dulness at base; respiratory sounds and vocal resonance very distant.

The family history was good, the father and mother and three brothers and sisters being alive and strong. The patient was ordered a mixed diet, with two ounces of brandy, and the following prescription:—

R. Vini ipecac. ℥ viij.;  
Tr. opii, ℥ iv.;  
Pot. nit., gr. viij.;  
Mucil. acaciæ, ℥ ij.;  
Aq. ℥vj. Ter die sum.

Oct. 8th.—Amphoric breathing was discovered at the right base, accompanied by pectoriloquy. Medicine changed to—

R. Ext. nuc. vom., gr. ʒ; ;  
Ext. aloes, gr. j.;  
Pulv. myrrha, gr. ij.;  
Saponis, q. s. 1 pil., o. n. s.  
R. Liq. arsenicalis, ℥ j.;  
Tr. Sunbul, ℥ xv.;  
Vin. ipec., ℥ x.;  
Inf. cascariellæ, ℥j. Ter die sum.  
R. Acidi carbolic, gr. xx.;  
Aque ferventi, ℔j. Vapor o. n. inhal.

Oct. 15th.—Physical Signs:—Right Side—Impaired more or less all over. Bronchial breathing at the apex; amphoric at the base; creaking and pectoriloquy at the base. Left Side—Breathing harsh.

16th.—Half-a-pint of blood-stained sputa and blood brought up. Ergot, ℥j., administered. Streaky hæmoptysis this morning. Haustus changed to—

R. Liq. morphia hydrochlor., ℥ v.;  
M. f. acid. rosæ, ℥j. T. d. s.

17th.—Evening temperature 100·4.

19th.—No more hæmoptysis; sputa large in quantity, purulent.

22nd.—Patient complained of pain at the left shoulder. Physical Signs:—Right Side—Impaired resonance anteriorly; breathing amphoric at apex; pectoriloquy and large moist sounds. Posteriorly: Impaired resonance from mid-scapula downwards, with cavernous breathing, pectoriloquy, and large moist sounds. Left Side—Impaired resonance from the angle of the scapula to the base; breathing distant.

26th.—Hæmoptysis yesterday, about a pint and a-quarter. ℥ij. of ext. ergotæ liquidum given. Haustus changed to—

Ext. ergot. liq. ℥ss.;  
Mag. sulph. ℥ss.;  
Inf. acid. rosæ, ℥j. T. d. s.

29th.—Last night hæmoptysis again; about three ounces of dark-coloured blood, not frothy. Ice given to suck and ext. ergot. liq. ℥ij. Pulse bounding and compressible; this morning feels better; pulse 84, weaker.

Nov. 9th.—Cough very bad. No more hæmoptysis. Ordered—

R. Tr. eriodyctionis, ℥xx.;  
Mucil. acaciæ, ℥j.;  
Aq. ad., ℥ss. Bis. dic. sum.

10th.—Liq. vesicatorius ordered to the front of the chest.

12th.—Cough better.

16th.—Right base, same physical signs; left, some crepitation.

19th.—Sputa less; cough better.

25th.—Right side, impaired resonance all over, with crepitation; apex dull.

26th.—Neuralgic pains in the head. Ordered—

R. Quinia sulph. gr. ij.;  
Acid. sulph. dil., ℥vj.;  
Inf. quassia, ℥j. T. d. s.

Dec. 10th.—Neuralgia better. Improving generally.

16th.—Cough less.

Without there being any marked change in the physical signs the patient's general condition was slowly improving. His voice was less hoarse under the combined influences of vapor acidii carbonici and vapor benzoini, the neuralgia was gone, the cough was much improved by the eryodryon, and on Dec. 21 the patient was considered sufficiently restored to leave the hospital.

*Remarks.*—This case is interesting as being almost the only case observed in the hospital during a period of three months in which there was any improvement after severe hæmoptysis.

## Transactions of Societies.

### OBSTETRICAL SOCIETY OF LONDON.

ANNUAL MEETING, WEDNESDAY, FEBRUARY 2, 1881.

Dr. W. S. PLAYFAIR, President, in the Chair.

Dr. GODSON exhibited two children, each of which showed a deep depression in the left frontal bone, the result of pressure from the sacral promontory during delivery. One, four days old, was delivered by forceps, the pelvis of the mother being much deformed, and, at the time of birth, the indentation was so great, that the bone appeared to have been fractured. The blade of the forceps encircled the left molar bone, quite clear of the depression, and had not slipped. The second child, seven weeks old, was also delivered by forceps. It appeared to him natural that the head, in first position, endeavouring to rotate into the antero-posterior diameter, should receive the pressure on the left frontal bone, when the sacrum was unduly prominent.

Dr. WILTSHIRE had seen several such cases of depression produced by the promontory of the sacrum, not by the forceps, in connection with rickety pelvis. Generally the depression did not persist, and it could sometimes be removed by atmospheric exhaustion. He had seen convulsions produced by deep depressions.

Dr. J. WILLIAMS did not see how a depression, so situated on the frontal bone, could be produced by the promontory of the sacrum.

Dr. FANCOURT BARNES had lately seen a child born with just such a furrow as was seen on one of the children shown by Dr. Godson. The sacrum was projecting, but forceps had not been used.

Dr. CARTER mentioned a case in which the pelvis was contracted to the conjugate diameter; labour was protracted, but the forceps were not put on till the head was in the pelvic cavity. The left parietal bone of the child had a depression large enough to contain the bowl of a dessert spoon. It had no symptoms of pressure on the brain, and, in about three weeks time, the bone had almost recovered its normal contour.

The PRESIDENT was inclined to think that the appearance of the depression in the younger child seemed to indicate that it might have been produced by the blade of the forceps, the skin being somewhat abraded.

Dr. GODSON, in reply, said that after the birth of the child he re-applied the forceps over the mark left by it. He was perfectly certain that the instrument was no factor in the causation of the depression.

Dr. GERVIS exhibited a modification of Hodge's pessary, in which the sacral end, instead of being, as usual, rounded, presented a considerable central depression. The advantages claimed for this, were that the tendency of the fundus to roll to one side of the pessary was obviated, and a much steadier pressure on the fundus was maintained. The makers were Messrs. Walters, Palace Road.

The PRESIDENT remarked that one form of Thomas's retroflexion pessary had a similar concavity of the sacral end.

Dr. BARNES said that the pessaries sold as his were not of the form in which he used them. They were made of flexible metal, and he moulded them himself, according to the conditions of each patient. He thought the square shape of the lower end of Dr. Gervis's pessary objectionable.

Dr. BURTON showed a specimen of

### EXTRA-UTERINE PREGNATION.

The patient, æt. 31, mother of five children, the youngest of which, seven months old, she was still suckling. The menses had been on from the 17th to the 22nd of January. On the 24th, at 5 p.m., while lounging in an easy chair, she had coitus with her husband. Towards the end of the coitus, she slipped forward over the edge of the chair, and immediately felt a sharp pain at the lower part of the abdomen, became faint, vomited twice, and had several actions of the bowels. When she was seen, at 10.30 p.m., she had severe pain at a defined spot, two inches from the mesial line. The pulse was scarcely perceptible, extremities cold, and she was evidently sinking rapidly from internal hæmorrhage. She died nine hours after the injury. At the post-mortem examination a large clot of blood was found filling the pelvic cavity, and extending some distance upwards towards the umbilicus. The right Fallopian tube, about an inch from the uterus, was expanded into a cyst about the size of a Barcelona nut, on the upper surface of which was a small opening. The cyst contained a fœtus of about six week's gestation. The left ovary contained a corpus luteum, quarter of an inch in diameter. The uterus was lined with a smooth decidua. Dr. Burton, by a negative process of reasoning, was led to the diagnosis of ruptured Fallopian tube, but considered it too late, when he saw the patient, to attempt operative interference.

Dr. WILTSHIRE said that this case was another, and an emphatic illustration, of the importance of carrying out, where feasible, a practice he had already repeatedly recommended in such cases, viz., the ligature and removal of the burst Fallopian tube.

Dr. McCULLUM on

### A CASE OF VILLOUS DEGENERATION OF THE ENDOMETRIUM.

The patient, æt. 51, was admitted into the Montreal General Hospital, Oct. 4, 1879, for metrorrhagia. Her mother died from melanotic cancer of the eye. After the menopause, which occurred at the age of 45, she suffered from leucorrhœa for several years. Metrorrhagia came on three years ago, and had recently become profuse. The uterus was less movable than usual, the sound passed three inches, and caused moderate bleeding. There was a greyish discharge from the vagina, which became offensive in November, and continued so until her death. She suffered severe pain, not constant, but periodic. She went out on January 8, but was re-admitted on May 13, being now emaciated and cachectic in appearance. The uterus had increased in size. The cervix was dilated with a laminaria tent, and more full dilatation was effected by four tents on June 9th. The whole surface of the endometrium was found to be covered with soft projecting granulations. These were scraped away with a curette, and fuming nitric acid applied. On July 16 dilatation was repeated. After removal of a second tent, symptoms of collapse came on, and she died on July 17th. The uterus was found dilated into a cavity large enough to contain a hen's egg. On the anterior wall was an ulcerated patch, as large as a crown. The rest of the uterine wall was thickened, and covered internally with villousities. A teased-out specimen of a villosity showed two elements; (1) cells epithelial in character, the majority of the columnar type; (2) a fibrous stroma made up of irregular spindle-shaped cells. Considerable doubt existed as to whether the disease should be grouped with malignant affections.

Dr. GALABIN thought that, from the characters of a teased-out specimen, there could hardly be a doubt that the case was one of the so-called cylinder epithelioma. It was clear, from the history, that it was clinically malignant, and distinct from simple forms of villous degeneration. He had met with several cases in which cylinder epithelioma affected the whole internal surface of the body of the uterus uniformly, so that it might appear, at first, doubtful whether the case was one of malignant disease at all. Such cases might possibly admit of eradication by extirpation of the uterus.

The PRESIDENT then delivered the Annual Address.

Dr. PRIESTLEY, in eulogistic terms, proposed a vote of thanks to the President. It was seconded by Dr. Gervis, and carried by acclamation.

### SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society was held on Friday evening, January 21st, 1881, in the Albert Hall, Royal

College of Surgeons, Dr. EDWARD HAMILTON, senior member of council of the Society present, in the chair.

Mr. TUFNELL, Hon. Sec., read the minutes of the previous meeting, which were signed.

Mr. Wm. WHEELER read a paper on

ANTISEPTIC SURGERY AS COMPARED WITH LISTERISM, which will be found at page 155.

Mr. TUFNELL said that having had an opportunity of seeing the majority of the cases detailed by Mr. Wheeler the facts were plainly put forward without exaggeration, and he could endorse what he had said that there had not been suppurative action.

Mr. THORNLEY STOKER rose to speak rather from the fear lest being present his silence should be taken as consent. He for one most utterly and entirely dissented from the views Mr. Wheeler had put forward. One or two points he would remark upon. He objected respectfully to Mr. Wheeler's christening of the form of surgery, which he termed antisepticism; he entirely objected to his terming one system "Listerism," and the other "antisepticism," implying that Lister's method was not antiseptic at all. Antiseptic surgery was associated with Lister's name, and antisepticism and Listerism were used as convertible terms. He also objected to Mr. Wheeler's right to christen his treatment of chloride of zinc and surgical cleanliness as "antisepticism," conferring the term "Listerism" as a reproach on something else; let him call his own method, if he liked, "Wheelerism," but let the term antiseptic be associated with Lister's treatment. There was one suspicious circumstance he should remark upon in the record of cases read to the Society. He had heard it often asserted and argued that other plans of surgical cleanliness might equal "Listerism," but he had never before heard a surgeon argue that Listerism produced worse results than any other system, yet that was the proposition which Mr. Wheeler had laid before the Society.

On the motion of Mr. FITZGIBBON, seconded by Mr. THOMSON, the debate was adjourned to next night of meeting.

The Society then adjourned.

#### ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, FEB. 7TH.

Mr. THOS. ARNOLD ROGERS, the newly-elected President, took his seat for the first time, and delivered his

#### INAUGURAL ADDRESS.

After thanking the Society for having, after an interval of sixteen years, again placed him in the position which he considered the highest in the dental profession, he proceeded to recall the events which led to the foundation of the Society in 1856, and to compare the present position of the profession with that of twenty-five years ago. The foundation of the Society was an outcome of the agitation which culminated in the establishment of the examination for the dental license of the Royal College of Surgeons of England. The appearance in the same year of the *British Journal of Dental Science* marked the commencement of periodical dental literature in this country. The Society, originally founded for political objects, had gradually settled down to a purely scientific basis, and now political matters relating to the profession were left in charge of its vigorous young relative the British Dental Association, on whose energy and sagacity they might place implicit reliance.

#### INTERNATIONAL MEDICAL CONGRESS.

Mr. Rogers, referring to this subject, said he had looked through the records of the previous congresses, but had failed to find any mention of a dental section. Obstetrics, ophthalmic surgery, otology, dermatology, were all represented, but dental surgery was ignored. He was surprised that their speciality had not been recognised at Philadelphia, considering the service which American dentists had rendered to this branch of surgery. But it was with corresponding pride that he recorded the fact that it had now at last received the official recognition of the surgical world. They should see to it that their proceedings on this momentous occasion should be worthy of the position accorded to them, and should also serve as a precedent for guidance and imitation at future congresses. The rest of the address was occupied

with a dissertation on the embryonic origin of the dental tissues—a subject which has long occupied Mr. Rogers' attention.

#### CASUAL COMMUNICATIONS.

Among the communications which followed,

Mr. ISIDOR LYONS related a case in which a set of artificial teeth had been swallowed during sleep. The patient awoke choking, and at once went to a neighbouring medical practitioner, who tried to push the teeth into the stomach with a probang, and then administered a dose of castor-oil. The patient, not being relieved, went to St. Bartholomew's Hospital, where Mr. Thos. Smith, having ascertained that the plate was still impacted in the œsophagus, removed it, after some trouble, with forceps. The treatment adopted in the first instance was generally thought to be very injudicious.

Mr. F. CANTON related the case of a boy, æt. 6½ years, who, although very intelligent, understanding all that was said to him, and making himself understood by signs, could not speak. He had never suffered from any serious illness, nor been subjected to any fright. The organs of articulation seemed perfect, and on one occasion, when about three years old, he had spoken one or two words, but could never be induced to repeat them. Mr. Canton asked for information as to the probable cause of the aphasia, and the prognosis.

A discussion followed in which several instances of late acquisition of speech were mentioned.

Mr. HUTCHINSON mentioned a family of four children, all bright and intelligent, yet none of them learned to speak until they were four or five years of age. The youngest, now aged four, could only say a few words.

Dr. WALKER instanced another family in which all the children were backward in talking, one girl not acquiring speech till the age of fourteen.

## The Mineral Waters of Europe.

### THE "MEDICAL PRESS"

#### ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, &c.

WITH

#### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P.Lond.,  
Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

*Continued from page 116.*

IN employing the bottled waters it is well to follow, as far as circumstances permit, the plan pursued at the Springs. The water should be warmed to 100 F. or higher. This may be accomplished by adding boiling water, or if that should increase too much the bulk of the dose, by allowing it to stand in hot water long enough to warm it. So, the quantity to be taken should be distributed over about an hour's active exercise, out of doors if possible. In some delicate persons it may be desirable to permit a cup of weak tea or warm milk, or milk and water to precede the dose, but the rule is to take it fasting. When only a small dose is given and little exercise taken, and that indoors, the fast must be broken by the mineral water. Then as to diet, it is most important for patients to co-operate with the physician, and therefore as much latitude as may be practised without detriment should be allowed. Much depends on the disease, and every case ought to be separately considered. Hence the difficulty of inelastic rules. Following the plan of the Spa we may advise simple breakfast, midday dinner, and a light supper. Most people, however, would like tea at 5, and supper

a little later, and this may be generally allowed; the tea consisting of tea with milk, biscuits or dry toast. It would also be better to remove the soup from the dinner, which should consist of two courses only, viz., meat, or poultry, or game, with vegetables, followed by light pudding. This would allow greater variety in the supper. We would also admit butter in moderation for breakfast. Ripe fruit, too, might very often be taken with advantage. These relaxations would be welcomed, by most patients, and in the majority of cases would do no harm, while in some special conditions other changes ought to be made. But no concession can be made to the lovers of malt liquors. The prohibition of alcohol should be absolute. Generally, even in moderate doses the waters act on the bowels, producing each day one, two or more copious, pulpy, slimy evacuations, which are sometimes of dark colour and offensive smell. Many patients are astonished at the quantity of material thus removed. Sometimes however, only a slight purgative effect is produced. The dose should be regulated so as to secure one, two or three full, soft stools soon after it, the bowels being at rest afterwards until the next morning. This may be kept up for three or four weeks or longer as may be necessary. To carry out this plan it may be necessary to give 2 or 3 glasses to begin with, and increase to 6, 8, or more before the full action is obtained, and then to diminish until the point is found which will keep up the effect desired.

A milder course of the bottled waters is sometimes of great value. This may be attained by taking every morning a dose of about half a tumblerful. In this case the glass should be filled up with water hot enough to bring the whole to a temperature at which it can be drunk. This is to be taken first thing in the morning, or sipped during dressing. It may be followed up by a cup of weak tea and a walk or gymnastics until breakfast—an hour after the water. These mild courses ought to secure one soft evacuation daily. In many cases it is desirable to precede the course by one or two aperient alteratives.

It is in disorders of the abdominal viscera that Carlsbad is chiefly recommended. In the "abdominal plethora" of the Germans, in the bilious and liver complaints of many English practitioners it has been employed with success. The remarks we have made on its general effects will enable the reader to understand why this should be the case, as well as why it should prove serviceable in corpulency. In lithiasis, in concretions of uric acid and catarrh of the urinary organs, and in gouty states, when the abdominal circulation is sluggish, the alkaline quality of Carlsbad indicates it in preference to many other salines, and from the new analysis of Prof. Tichborne we find that these waters contain lithia—the alkali which is specially suited for these conditions. The discovery is one of great interest. Carlsbad is also recommended in hæmorrhoids, provided the patient be corpulent, possess sufficient stamina, and is relieved rather than injured by the occasional bleeding caused by the malady. But in weak and emaciated subjects, with tendency rather to atrophy than engorgement of the liver, and who, instead of finding relief, are made much worse by the loss of blood, all purgative saline courses are contra-indicated. In enlargement of liver or spleen due to malaria, or in congestion of these or other

viscera from overfeeding and want of exercise; also in tendency to gall-stones; in most ailments due to sluggish portal circulation, the treatment is effective. It may also be employed to deplete in venous engorgement. In disorders of the stomach and bowels it might seem less applicable than other waters, but it is often used in catarrhal states of the mucous membrane. Lastly, Dr. Seegen reports good results in diabetes. It would seem the cases of this disease should be preferred in which the abdominal viscera seem to suffer, while Vichy would be preferred for other cases. But we need not dwell on this point, as the imported water is not likely to take more than a very subsidiary part in the management of this disease. In female diseases, if dependent on abdominal engorgement or sluggish portal system, the mild course we have sketched above is often a potent auxiliary to other treatment; and the same may be said wherever there are indications for a course of gentle saline, alkaline, purgative waters.

The Sprudel is the most generally used spring, and, from our analysis, seems to give the most concentrated water. It is richer in purgatives as  $12\frac{1}{2}$  to  $6\frac{3}{4}$ , and the dose should be smaller. A more important indication is that it has more antacids than the Schlossbrunnen, 10.5 to 7.01. In these antacids we notice that the Sprudel has double the quantity of lithia, and the carbonate of soda is also in much greater quantity than in the Schlossbrunnen. The latter, then, should be used where the milder effects are desired, but the Sprudel for obtaining the full action of the waters, especially in gouty subjects, or where alkalies are indicated.

*Marienbad.*—These waters resemble those of Carlsbad, but are more concentrated, and contain more carbonic acid. The springs are also cold. These differences are all in favour of the exported waters, as they should in consequence be bottled with less change, and keep better. The dose, too would be smaller. A study of the analyses indicate what has been found by clinical observation—that Marienbad and Carlsbad may often be made to serve for each other. Marienbad is, in fact, cold Carlsbad, but stronger; or, to put it in the opposite way, Carlsbad is hot Marienbad, but weaker. The two spas are thus, to some extent, rivals. Marienbad, indeed, makes no claim to help diabetic patients, though, on the other hand, she vaunts the iron in her waters, and holds them to be more tonic. We do not think iron of much value in this class of waters, for it is at once precipitated as a sulphuret. The considerable amount of carbonic acid in Marienbad is also said to make it stimulant, and it certainly is agreeable to both palate and stomach. To this gas is probably due the repute of the waters for being easily digested, although cold. On the other hand, the disengagement of carbonic acid in the stomach sometimes is a disadvantage, but then the water may be allowed to stand. In these cases, too, it is usually better to give warmer waters, but Marienbad will bear dilution with hot water for this purpose, as it is richer in antacids, as well as aperients, and each of the springs contains lithia. Thus, the cases are numerous in which either spa would be beneficial, the chief differences being regulated by the temperature, and degree of concentration of the waters and the amount of the gas present. Where the aperient action is most desired and a cold spring is suitable, Marienbad is preferred. In

weaker persons, with poor circulation and defective heat-producing energy, in catarrhal conditions of the alimentary canal, and where carbonic acid is not agreeable, Carlsbad is preferred.

The use of the bottled waters may be inferred from what has preceded. Marienbad is a stronger Carlsbad, and may be substituted for it when it is desired to increase the effect of the purgative and antacid ingredients; but where the bulk of larger quantities of Carlsbad is objectionable, Marienbad may be given cold, or it may be warmed sufficiently without losing all its carbonic acid. Further, by diluting Marienbad with rather less than its own bulk of hot water, we obtain a draught closely approximating warm Carlsbad, as may be seen from our analyses, which give, in 10 oz. of the Ferdinandsbrunnen spring of Marienbad—22 grains of purgatives, and 18½ antacids, as against 13½ of the former and 10½ of the latter in the Sprudel of Carlsbad. The dose is to be regulated accordingly. A mild course, such as that sketched in our remarks on Carlsbad, may be begun by a morning dose of two-thirds of a tumblerful, filled up with hot water. If, after two or three days, this does not act on the bowels, the quantity must be increased. The diet and regimen advised under Carlsbad must be observed.

*Tarasap* has become more known in England of late years, and belongs to the same class of waters. It contains as much sulphate of soda as Carlsbad, but nearly three times as much carbonate, and more than three times as much common salt. Where more antacids and salines are required it is therefore available. The adjuvants seem to increase the aperient action of the Glauber's salt. The water contains so much carbonic acid that it may be warmed when required. The average dose may be a pint daily, half of which may be taken before breakfast, and the remainder between that and a mid-day dinner. *Tarasap* is by some advised in bronchial and pulmonary affections, complicated with abdominal stasis. But the question of climate here occurs, and at present we are only dealing with the bottled waters. These may be used instead of Carlsbad, bearing in mind the differences we have stated.

*Franzensbad* is a cold spa, the strength of which is between that of Carlsbad and Marienbad, but it contains less carbonate of soda than either. It is sometimes called chalybeate, but contains little iron, and that, as we have seen, is not important in waters of this kind.

*Elster* (Saxony) resembles the last, containing a little more sulphate and a little less carbonate of soda. *Füred* and *Stubnya*, in Hungary, *Rohitsch*, in Styria, and *Bertrich* (Mosel) belong to this group, but are weaker. All are, no doubt, useful to their districts, but it would detain us too long to examine minutely their differences. The physician who has studied the subject of mineral waters will be able to advise respecting any difficult case.

This group of waters, however, must not be dismissed without reference to our own English *Leamington*, which is rich in sulphate, though not in carbonate of soda, and where many of the advantages of a foreign spa may be enjoyed, especially if the waters be supplemented by others. For example, many cases would do well at *Leamington* if they took small quantities of *Vichy*, or some other alkaline water. Other combinations might be arranged, but this

suggestion should suffice to show the scope of the British Glauber's salt spa.

(To be continued.)

WEDNESDAY, FEBRUARY 23, 1881.

MEDICAL ATTENDANCE INSURANCE.

THE progress made by the dispensary movement during the few years it has been prominently advocated, and the yet more universal approval accorded to sick and doctors' clubs among working populations, is one of, and perhaps the best indication there is, that it is not always from choice the resort is had to gratuitous hospital relief. For some considerable time, the question of out-patient relief reform has been a constant subject of anxious consideration with those who are familiar with the administration of our chief charities. Schemes for reducing the excessive extent to which charitable funds are drawn on to meet the demands made by out-patient claimants have, from time to time, been mooted; but each of these has been in some respect or other faulty, and it yet remains for an adequate suggestion to be made. What is required is a plan, by the working of which the poorer classes of the population shall be able to secure the advantages of regular and skilled attendance in time of sickness, and at the same time be called upon to contribute in payment no more than can reasonably be spared for this purpose. It is obvious that if the doctor is to receive payment for his duties only during the period they are actually rendered, either it must be miserably disproportionate to the value of his time and attention; or, if sufficient to repay him, it must seriously cripple the resources of the patient or his friends to meet the outlay.

The difficulty is one of time and arrangement, and it is happily adjusted in some districts by the adoption of the club system, according to which the members pay, at all times, a fixed weekly or monthly subscription; and in return they are attended and, according to the terms of agreement, may be supplied with medicine also so long as they continue to need professional advice. This plan is one that commends itself to approval, on account of the opportunity it offers to the poor to exercise their spirit of independence, and exert the right of calling in a medical attendant rather than seek the aid of one as a favour conferred, though it be by an institution. The pauperising influence of gratuitous charitable assistance is one to be fought against, and the intelligent mechanic is among the first to recognise the truth of it. Spite, however, of the good features possessed by the club system when rightly carried out, it is capable of, and unfortunately is, being made the means of what can only be regarded as most unprofessional attempts to coerce the public into employing particular practitioners. The fact that the sick club limits the choice of its members, is the one great drawback to its efficiency. We hold that unless a patient is absolutely free to choose for himself who shall attend him during illness, there is exerted over him a controlling power which no other person has the right of assuming. In country districts, where but a few medical men are located in a wide area, it must necessarily happen that the club officer is one of a few, or he may even be the only available person in the neighbourhood. This is a condition that is the outcome of the situation, but that it is a blot on the club system is admitted by most of those who have carefully considered the subject. It is eminently desirable that the rules of any medical insurance club shall provide for free choice on the part of the contributor to its funds, provided that is of course, that the selection is made with reasonable regard to the fees usually received by the attendant chosen. The remuneration of the latter should then be made by the chief secretary; and in any district it would be an easy matter to receive the assent of resident practitioners to attend cases when called to them at a regular fixed fee payable according to a scale arranged with the general consent. In this way no single man's services would be forced on patients, the interests of the latter would be conserved through the wish of the medical man to strengthen the favourable impression they may succeed in making, and far greater satisfaction would exist among the contributors to the fund of the society. We have been thus explicit in describing the manner in which we conceive a really practical and trustworthy insurance scheme should be worked, because we have had our attention drawn to what is called the "General Medical Attendance Insurance," and which we cannot but regard as based on principles radically at variance with the broad laws laid down above. This association solicits subscriptions from three classes of members; it professes its object to be: "To provide city clerks and other people with limited incomes with the best and most experienced medical advice, at definite charges." This is condemnatory when taken in connection with the fact that one medical man only is offered as the source whence the best and most experienced medical advice is to be drawn. We do not

raise any question of this gentleman's professional attainments, but were he as much a physician of to-day as Galen was of his day, it would still be improper to the highest degree to dub his diagnosis the best and most experienced. One man cannot be "best and most experienced" on every subject that comes to him in general practice; and it is significant that those whom we are wont to regard as lights of learning in medicine, and monuments of experience, are the most eager to disavow the encyclopædian capacities assumed for the gentleman who is medical adviser to the "General Medical Attendance Insurance." The elegant announcement of this company is made up, apparently, with the business-like aim of attracting the non-medical reader, by presenting for his perusal a series of assertions, that the initiated will find some difficulty in crediting. For instance, "N.B. The physicians and surgeons must, in addition to the usual qualifications, have been attached to a public institution for ten years; five of which must have been at a hospital recognised by the College of Physicians and Surgeons." This is, if it means anything, intended to convey the impression that only such gentlemen as have been, or are, on the medical staff of a recognised hospital, will be eligible for election on to the staff of the new company. But that this is not really so, we imagine, the following extracts from the latter's advertisement will sufficiently prove.

The Society is divided into the three following sections:

SECTION A.—By payment of one guinea a policy is issued which insures the holder thereof medical, surgical, and dental advice when required for the space of one year. Medicines can be obtained at any of the appointed chemists, at moderate rates.

SECTION B.—Working men and women (proved to be such), can by payment of 2s. 6d. entrance fee, and 1s. at each attendance, obtain medical, surgical, and dental advice with medicine.

SECTION C.—This is for poorer members, who must bring a letter of introduction from a subscriber of not less than 10s. 6d. per annum, when they will pay 1s. the first time, and 6s. each attendance after.

This indicates that a hospital physician or surgeon, after five years' connection with the institution he has served, will be content to visit and prescribe for something less than 2s. 6s., a depth of misery to which, even in these bad times, we trust but few hospital officials have descended. From our point of view, the medical student, who has been five years as a pupil and dresser at "a recognised hospital," and perhaps the preceding five years as laboratory assistant, or junior clerk in the counting-house, maintaining any sort of a connection with the hospital, is eligible for a staff appointment on the new company. Regard it as we may, indeed, it bears the evidence of being a trading concern; and even though it had been the most praiseworthy, it would still be totally barred, in that it restricts its member's choice of attendant. As it is, we cannot but regard it as a new departure on the line of professional degradation; it is worse than, because more pretentious than, the "advice and medicine 4d." dispensarists, and the medical gentlemen associated with the concern must consent to be regarded as retrograding from the strict professional path.

#### IRISH MEDICO-EDUCATIONAL REFORM.

The profession in Ireland is, at the present moment,

face to face with very momentous changes in its educational system—changes which mean nothing less than the disruption of the certificate system, the credit-fee system, the apprentice-farming method of livelihood, and the three-course lecture arrangement. Just as the process of admitting students to the practice of the profession by virtue of a bogus apprenticeship to a surgeon came to a well-merited over-throw forty years ago, so is the certificate system now tottering to its fall, assailed by the united efforts of those who refuse any longer to countenance or participate in the disgraceful system of selling parchments at three guineas apiece, and receiving such documents as proof of professional attainments.

Corrupt practices die hard whenever they are lucrative; and as the sham certificate system in Dublin has made the fortunes of many persons engaged in it, it is not to be wondered at that it has been sustained, defended, apologised for, and fostered by every means, open or underhand, and by every influence which it was possible to gather to its aid. While the rank corruption of the system stank in the nostrils of every one who had occasion to approach it—of surgeons who had been victimised by it, of patients who bled for it, of students who were being sacrificed to it, of teachers who blushed for it, and of examiners who had daily proof of the effects of it—it was, nevertheless, tolerated, connived at, and even encouraged, by certain persons, as being, if a little dishonourable, at least very profitable; and the pioneers of the present movement for a reform were tabooed as Quixotic nuisances, cursed with a conscience, and to be kept out of any positions in which they might have a chance of ventilating their inconveniently purist ideas.

Four separate attacks on the Irish teaching system, as it now exists, are about to be delivered. In the first place come the medico-educational regulations of the Royal Irish University, which are now in a state of completion, needing only the approval of the Lord-Lieutenant and of Parliament to make them law.

Our readers are probably aware that for the whole of last summer the academic programme of the New University was under deliberation by a sub-committee of the Senate. To that sub-committee a scheme for the medico-surgical arrangements was submitted by one of the members, and by them it was discussed; but, inasmuch as the medical members of the Senate were very insufficiently represented in this committee, it was decided by the Senate to remit the scheme to the medical representatives, and they have accordingly considered it, and, we believe, expressed their opinion on it. *Apropos*, we may here recall the fact that surgery is altogether unrepresented amongst these representatives—a circumstance which suggests the possibility that Anatomy and Surgery, and their cognate subjects, may be neglected in the programme of the New University.

We append an abstract of the scheme as it stood, subject to the suggestions of the medical element in the Senate; but we desire it to be understood that we do not put forward this abstract as representing anything final, but simply as illustrative of the principles upon which the medico-educational arrangements of the University are likely to be framed.

The R. I. U. will grant the degrees of M.B., M.D., and

M.Ch., and a diploma in obstetrics. To obtain the degrees of M.B. or M.Ch., the candidate must pass—

- (a) The Ordinary Examination in Arts (being practically identical with the existing preliminary of the Irish College of Surgeons.
- (b) Three University Examinations in Medicine.

To obtain the complete double qualification—with the Midwifery Diploma. The suggested university fees are:—For the two primary examinations, £1 each; for the final M.B., £3; for the M.Ch., £5; for the Midwifery Diploma, £2, equal £12.

*For the 1st Professional Examination* the student shall produce certificates of one course of lectures in—*a.* Physics; *b.* Botany; *c.* Anatomy; *d.* Practical Chemistry; *e.* Zoology. His examination will be in Physics, Botany, and Zoology, and a Modern Language (if he be not an Arts student).

*For the 2nd Professional Examination* he must produce certificates of one course on—*a.* General Anatomy; *b.* Dissection; *c.* Practical Histology; *d.* Materia Medica and Therapeutics; *e.* Medical Jurisprudence; *f.* Practical Pharmacy, eighteen months hospital. He shall be examined in Anatomy, Physiology, Materia Medica, and Chemistry.

*For the 3rd Professional Examination* the student shall produce certificates of one course of—*a.* Anatomy; *b.* Dissection; *c.* Physiology; *d.* Medicine; *e.* Surgery; *f.* Midwifery; *g.* Vaccination. Nine months general and three months midwifery hospitals. He shall be examined in Anatomy, Surgery, Practice of Medicine, Midwifery, Medical Jurisprudence, and in Clinical work. The Diploma in Midwifery will be given only to M.B.'s on special Midwifery Examination.

That we should attach extreme importance to this programme, on the presumption that it represents at least approximately the future arrangements of the New University, will be easily understood when we compare the cost in time, labour, and money of two full qualifications in that institution, and of the Double License of the two Irish Colleges at present prices. To obtain the L.R.C.S.I and L.K.Q.C.P.L. requires nominally four years of study, three separate examinations in two separate institutions, and a total money outlay of about £158. The New University will give its Double Degree on, practically, three examinations, conducted in the one institution. It will require much fewer courses of lectures, and twenty-four months hospital instead of twenty-seven, requisite for the Dublin double diploma. Its total examination fees will amount to £12 as against £43. But there is more than this. Bribes of enormous amount are offered to students to patronise the new institution. Each student who passes with first honours is to receive at his first examination, £35; at his second, £45, and at his degree, £60. Each second honour man is to receive for his first examination, £20; for his second, £35, and for his degree, £40. The respective total for the three years being—for a first honour man, £140; for a second honour man, £96. In other words it is proposed that the New University shall reward the diligence of a first class student with a sum which will pay for his entire education and degrees, and leave him about £50 in hand towards his maintenance during studenthip. It is hardly necessary to point out that the competition of degrees granted under these circumstances could hardly be successfully sustained by any colleges, however high their prestige, and that, if these arrangements should be finally adopted, there is

absolutely no escape from a wholesale reduction in the number of courses of lectures and the diploma fees now required by the Irish colleges—except, indeed, salvation may be found in the passing of a Medical Act which will provide for Conjoint Examination and thus level up under-bidding Universities and level down over-greedy Colleges to a fair educational grade.

The second influence to which we look with confident hope as a means of Irish medico-educational reform is a new scheme of curriculum and examination which has been under incubation by a committee of the Council of the Irish College of Surgeons for many months, and, being at length completed, has been received by the Council subject to amendment of detail. This scheme, if it should become College law, will provide,

a. That the study of medicine and surgery shall occupy four *bonâ fide* years and not two years and nine months as at present.

b. That a definite proportion of his course of study, suitable to his educational position, shall be taken by the student in each year, and that he shall not advance to higher studies until he has passed an examination at the end of his year to show that he has made good use of his time and opportunities.

These are the chief principles of the scheme, and they are such as every one who desires honest education efficiently pursued ought to approve. No one will profit from such an arrangement so much as the student himself, and no one will lose by it save the idler or his apprentice-master who have, heretofore, been permitted to force the chief part of his education into his last year, and thus make a net profit out of the pockets of the teachers whose fees were diverted for the advantage of the "farmer."

The third influence to which we look to obtain a better state of things than at present obtains is a scheme which is now being matured to secure what is called "sessional registration of students." At present—in certain schools—the entry of the students, though supposed to be effected not later than the 25th of November in each year is, in reality, effected at any time the student pleases, perhaps in the succeeding spring when the lectures are nearly over; perhaps many years afterwards when, on the faith of the student's own assertion, a certificate of diligent attendance at a course for which he had never been entered at all, may be purchased for three guineas. This is possible, because there has, hitherto, existed no record of the date of entry of any student. But last summer the University of Dublin showed the example, which we trust to see followed by every licensing body in Ireland, of requiring from each school a return of all its students who contemplate seeking University degrees, the date of their entry, the number of lectures delivered on each subject, and the proportion of that number attended by him. This return the University accepts as equivalent to a bundle of certificates, and admits the student named therein to examination without requiring further testimonials of "diligent" attendance or anything else.

It is proposed to extend this system to all Irish schools and licensing bodies, and a joint committee of the Colleges of Physicians and Surgeons are in sitting for the purpose of arranging details and seeking the co-operation of the diploma-granting bodies in the reform.

Thus we have indicated our grounds for congratulation upon the approaching demise of Irish medico-educational abuses. No doubt so complete a revolution will take time, and, in such a cause, time is well spent; but we are confident that at length a strong and universal feeling has been aroused, that the dishonesties heretofore permitted should be no longer tolerated, and that the efforts of those who seek for improvement must not slacken until the bogus-certificate system, with all its attendant tricks, becomes a thing of the past.

#### YOUNG SOLDIERS AND WAR SERVICE.

EVER since armies existed, practical experience in war has shown that only the men of physique and of mature age can be looked to as likely to withstand the combined effects of hardship, exposure, and fatigue incidental to protracted service in the field. From times the most ancient this fact has been acknowledged by commanders. Medical officers, from time to time, when their opinions were first considered of importance in the sanitation of forces have continued to raise their voices against the system of boy soldiers. Royal Commissions have followed in the same strain; and yet against the whole combined weight of practical experience in war this most pernicious system has been persisted in, merely because apparently a few theorists have so willed it. Now that the subject has been brought before the authorities and the public by a distinguished officer fresh as it were from victory, it is to be hoped that full consideration will no longer be denied it. As well observed by the distinguished officer alluded to, it is not the losses in battle that cause the long casualty roll in a campaign, but the steady never ceasing disease brought about by insufficient and badly cooked food, hard work, night duties, and exposure to extremes of heat and cold. Against all these, only the strongest men can bear up, the weakly must, and do, fail; they dwindle away, dead, or what on active service complicates work even more than that, their inability to march by reason of sheer physical weakness, requiring, in consequence, to be carried, their carriers, whether human or animal, to be fed and protected, thus very materially adding to the impedimenta, while they decrease the effective numbers of a force. In India, the fact is well known to all who are in authority, that large numbers of newly-arrived recruits are sent direct to hill stations on landing, there to be retained, some for one year, others for longer periods; that in the meantime, while they are under the transformation into men, obtaining food, accommodation, and pay, for duties which they do not in reality perform, the older and stronger soldiers at the head quarters of their respective regiments have to undergo the additional wear and tear incidental to the increased duties thus thrown upon them. It follows, therefore, that the system of short service, as applied to India, has the double objection, that it diminishes the number of soldiers who are effective, and increases the wear and tear upon them. From a purely medical point of view, the system has the further great objection, that under it the age at which the great majority of soldiers are exposed to the ordinary causes of endemic diseases is that when their susceptibility to these causes is at its maximum, their

power of resistance is at its minimum. All this has over and over again been urged by army surgeons, but hitherto without any actual result. Now that the statement has been directly made that "during the late Afghan war the boy regiments broke down without exception," it is surely fair to appeal to the authorities in the words of the first Napoleon to send out "men, not boys; boys serve only to fill the hospitals and encumber the road sides,"—unless carried along, much to the encumbrance of a fighting force. Humanity as well as military considerations point to this, so also does economy. More efficient, more economical to the State than an army of boy soldiers, would be one composed, as formerly was the case, of old trained soldiers inured to military duties and hardships, with a sprinkling of young men, in their turn to pass into a similar category, and ultimately obtain as rewards for good work performed pensions sufficient to maintain them in respectability in their old age. According to statistics, the rate of combined loss by death and invaliding is now considerably greater than under the long service system it was many years ago in India. It thus follows that good effects naturally anticipated from the great cost at which sanitation has been pressed on in regard to British troops in that great Dependency have been absolutely neutralised by this one measure, namely, the introduction of the short service system and constant influx of young immature lads incidental to it.

## Notes on Current Topics.

### The Hunterian Oration.

THERE was no doubt possible to be entertained that the Hunterian Oration of 1881 would be an eminently eloquent vindication of the life and aims of the great anatomist. Mr. Luther Holden could, and did, render ample justice to the subject he was called upon to treat, but we venture to think that the time may fairly be said to have arrived, when we are entitled to expect something more than two yearly repetitions of a well-known story as the product of the Hunterian bequest. It would surely redound fully as much to the honour of John Hunter's name, if on the day that this name was brought prominently to notice, and the memory of his deeds revived afresh, there should be laid also before the world of medicine something at least worthy of ranking with the giant intellectual efforts of Hunter. The Council of the College of Surgeons is trembling for the future, and it will best help to re-establish itself in general favour, by urging on the progress that distinguishes our age. By creating a research prize in connection with surgery or anatomy, and awarding this as a memorial of John Hunter, in place of biennially listening to his merits from some past president, or already eminent Fellow of the College; the latter would be legitimately stimulating the spirit of emulation in younger men, and properly affording them an opportunity of professional distinction. As it is, we venture to think the advantages to science are very limited in extent that follow from the Hunterian oration, while the honour done to Hunter grows less and less with the lapse of every year permitted to pass, without one effort to convert the festival day into one com-

memorative of renewed discovery, as well as of retentive memory.

### The Dreadnought Hospital.

THE annual report for 1880 of the Greenwich Seamen's Hospital, records that 180 beds were constantly occupied, the average for the preceding six years having been 164. In connection with it a dispensary has been opened in Well Street, London Docks, and is found to be of much service to sailors. This, as well as many other improvements bearing on the general management of the parent institution, has been due to the energy and perseverance of Mr. H. C. Burdett, the late secretary. The services rendered by Mr. Burdett to the hospital have been cordially acknowledged by the Committee, who have joined in presenting a memorial to him on his departure from the secretarial post. The work of the institution has progressed most smoothly during the past twelve months; and in every way the outlook before it is satisfactory.

### Memorial to Surgeon Power, R.N.

A LATIN cross, over six feet high, has been erected in the Naval Cemetery at Haslar, Gosport, in memory of the late Thomas Power, Surgeon R.N. The cost of the memorial has been defrayed by subscription among the brother officers and shipmates of the deceased surgeon, the extent to which his loss is felt being thus eloquently testified.

### Treatment of Transverse Fracture of the Patella.

INSTEAD of Malgaigne's hooks, which often cause supuration of the knee-joint, Kocher (*La Presse Medicale* from *Centr. für Chir.*) proposes to have recourse to the following procedure: By means of a curved needle he passes a loop of strong silver wire under the patella. He inserts the needle into the tissues immediately under the inferior border of the lower fragment, and brings it out above the superior border of the upper fragment. Small incisions in the skin at the points of entry and of exit of the needle, prevent the cutaneous investment from hindering the free passage of the thread. On the other hand, if sanguineous effusion prevent complete coaptation, it is evacuated by puncture. The ends of the silver thread are brought together and twisted over a carbolised compress. All is done according to Lister's method. The limb is then put up immovably. At the end of a few days, and sometimes after forty-eight hours, it is necessary to tie the ends of the thread tighter to bring the fragments into complete apposition.

Latterly, suture of the bone has been much recommended in fracture of the patella with great displacement of the fragments. Volkmann nevertheless thinks that opening the joint is not always advisable, and, as a rule, he prefers suture of the patellar tendon when the ordinary apparatus does not succeed in maintaining good coaptation of the fragments.

### Birmingham General Hospital.

THE 101st report of the General Hospital at Birmingham, has just been issued to the subscribers. The number of patients under treatment during 1880 is put at 30,785, exclusive of 4,876 dental cases. The expendi-

ture on these has been £18,419, but of this sum £5,150 is reckoned as "extraordinary" expenditure, on account of building extension. The average cost per bed within the hospital is put at £52 8s. 2d., this being nearly 28s. under the average of the preceding year, and 68s. less than that of 1878. In-patients have shown a slight falling off, but there has been an increase of 5,605 among the out-patient cases. The report adverts to the gratifying proof of interest shown in the charity by the working classes, by the steady increase in the amounts received from the Hospital Saturday collection. In 1880 the General Hospital received an additional £157 from this source. The resignation of Mr. W. P. Goodall, Surgeon to the hospital, from declining health, is referred to in the report; and a resolution of sympathy with that gentleman, passed by the Committee, finds a place in it. It is somewhat curious that the last paragraph of the report contains an intimation that the thanks of the governors continue to be due to the medical staff, for the services they render to the sick poor. Though this is a customary mode of acknowledgment, and by no means peculiar to Birmingham, it is nevertheless singular that those to whom the efficiency of a hospital is primarily due, should be the least conspicuously mentioned in annual reports of work done.

#### Extraordinary Proceedings of the Royal Microscopical Society.

At the anniversary meeting of the Royal Microscopical Society, on Wednesday week, Dr. Lionel Beale vacated the Presidential chair to Dr. P. Martin Duncan, F.R.S., and who was elected, not for work already done, but, it is hoped, about to be done, for Dr. Duncan is one of the youngest Fellows of the Microscopical Society. Indeed, it would appear that the Council laboured under some difficulty with regard to the choice of a President. Ultimately this was surmounted by taking the Fellow with the greatest number of letters after his name. Dr. Beale, in his parting address, made a rather virulent attack upon the Darwinian theory of evolution, which seemed to fall somewhat flat upon his hearers; for whilst it has been the usual custom of the Society to request the President to allow his address to be printed and circulated, no one ventured to propose that this should be done. It is as well that the Society should hesitate before plunging into a dispute over rival evolution theories.

The Council has, without consulting the wishes of the Society, determined upon rejecting the handsome offer of a provincial Fellow and an eminent member of the profession to found a medal, of the value of ten guineas, to encourage improvements in the microscope, as also another and similar offer for the encouragement of microscopical research. Upon what grounds this decision was come to has not transpired. Very probably the Council, having a fear before it that a Court of Equity might be induced to look very unfavourably upon the misuse of the Quekett Medal Fund, desire to have nothing more to do with an award of medals of any kind. Some fifteen years ago, on the death of Professor Quekett, the Fellows of the Society, desiring to perpetuate the valuable services he and his brother had rendered to microscopical science, subscribed a sum of money to found a medal which should bear his

honoured name. But, singularly enough, the medal has only once been awarded, and then to a gentleman who had contributed nothing to the Transactions of the Society, and since which time the funds have been entirely diverted to another and different purpose—viz., to the purchase of books for the library. Those members of the Society who entertain a regard for the name of Quekett, and look upon him as a very Nestor of microscopical science, have a right to ask for the faithful discharge of a sacred trust on the part of those who manage—or rather mismanage—the Society's affairs.

#### Dental Protégés of the General Medical Council.

IN the minutes of the recent meeting of the Council, to which we referred last week, we find the following histories of persons whom the Medical Council has inscribed in the official Register as duly qualified dentists. We offer them as specimens of the class of persons whom the Council consider to be up to their idea of capacity for the practice of dental surgery.

1. Christian Ackermann, 88 Victoria Dock Road, Canning Town, London. A German.

Was apprenticed to learn *hair-dressing* in his own country, where they always learn dentistry and dressing in a general way.

Served three years as dresser in a German Hospital.

Now carries on the business of hair-dresser and dentist.

Admitted ignorance of the anatomy of the mouth. Does nothing but extract.

Wife has a tobacco-counter in the shop, has "Registered Dentist" painted outside his window.

2. August Leopold, 65 Bunhill Row. A German.

Served his apprenticeship as a *barber*. Produced certificate of apprenticeship, showing that he had also learnt dentistry, cupping and bleeding.

Now carries on the business of hair-dresser and dentist. Does nothing but extract, scrape, and stop with gutta-percha.

Admitted his ignorance of the anatomy of the mouth.

Has a tablet outside his shop, on which is painted, "Dentist, Registered by Act of Parliament."

This is the class of persons whom the Medical Council recognises as dentists. And on what ground? One of the champions of these gentlemen approved of their being so recognised because of their "intelligence and truthfulness," and wanted to know "what is dentistry?" instancing the case of one successful dentist, who began life about half-a-century ago, simply as a tooth-puller, as if that fact supplied a reason for making dental surgeons, some fifty years later, of many hundreds of persons of the class illustrated above.

Another member of the Council thought that they ought to be admitted because of the "frank, straightforward way" these men answered the questions put to them. Are we to understand the capacity to give a coherent reply to a plain question, is the educational standard fixed by the Medical Council for British dental surgeons?

THE new buildings of the London Temperance Hospital in the Hampstead Road will be opened on Friday, March 4th, by the Lord Mayor, who, with the Sheriffs of London and Middlesex, will attend in state. The buildings, when complete, will hold fifty in-patients.

### The London Fever Hospital.

WHY is it that many sham medical charities in London have no difficulty in raising their thousands per annum, while the London Fever Hospital could only scrape together £660 during the whole of last year? Scarcely a hospital can be named which is of such absolute necessity to the well-being of the whole community; yet the veriest quack institution comes in for more liberal support. There must be a reason for this. Is it that the authorities are above, or fail to understand the value of, pathetic appeals to the tender feelings of the money-giving public? or is it because the very ring of the word "fever" is occluded from the ears of all but those unfortunate victims of it and the medical men and nurses whose painful duty it becomes to tend the patient and prevent the spread of contagion? If the latter be the reason, the public may some day have to deplore their short-sighted policy when too late.

THE Sussex Eye Infirmary is to be rebuilt, in order to meet the increasing requirements of the county, and of Brighton in particular.

A PETITION has been presented to Parliament by Mr. Cohen, M.P. for Southwark, in favour of the appointment of a Commission to inquire into the general management of Guy's Hospital.

THE vacancy of Honorary Physician to the Queen created by the decease of Dr. Davidson, has been filled by the appointment of Dr. J. Watt Reid, Director-General of the Navy Medical Department.

LAST week there were 89 deaths in Paris from typhoid fever, 39 from small-pox, and 32 from diphtheria and croup. In New York 42 died of scarlet fever; in Brooklyn 41, and Berlin 34 deaths were attributable to diphtheria; whilst in Philadelphia and Vienna 42 and 26 died of small-pox respectively.

MR. JOHN O'DUFFY, well known in Dublin as a dentist, and as having been very active in the medico-political agitations which preceded the passing of the Dentists Act, was last week acquitted of a charge of having made use of the name of another person in a telegram relating to his own private affairs. It cannot but be satisfactory to the dental profession that one of its members should be declared guiltless of so serious an accusation.

TELEGRAMS have been received from Dresden to the effect that a shocking accident happened at Munich while a number of students were supping together, in costume, on Friday. One, dressed as an Esquimaux, caught fire from a cigar, and ran against the others. The dresses were of such an inflammable description that four of the victims were burnt to death in the room, four others died the next day, and six others are badly injured.

THE rates of mortality last week in the principal large towns of the United Kingdom were—Portsmouth 13, Sunderland 16, Bristol 17, Leicester 18, Edinburgh 18, Sheffield 20, Bradford 20, Wolverhampton 21, Newcastle-on-Tyne 21, Hull 21, Birmingham 22, Salford 22, Lon-

don 23, Plymouth 23, Leeds 23, Brighton 23, Nottingham Norwich 25, Manchester 26, Glasgow 27, Liverpool 28, Oldham 31, Dublin 41 per 1,000 of the population.

IN the large towns last week scarlet fever showed the largest proportional fatality in Wolverhampton and Nottingham; and whooping-cough in Leeds and Nottingham. Of the 40 deaths referred to diphtheria, 17 occurred in London, 12 in Glasgow, 3 each in Dublin and Edinburgh, 2 in Liverpool, and 2 in Portsmouth. The death-rate from fever, principally enteric, was highest in Newcastle-upon-Tyne, Nottingham, and Leicester. Small-pox caused 54 more deaths in London and its suburban districts, but not one in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE MEDICAL PROFESSION AND ITS AMENITIES.—It scarcely speaks well for a profession that prides itself on its sympathetic attitude towards the public, for its members to be fighting for appointments held by a deceased member before even the first sad offices have been performed towards the dead. On the very evening of the day on which the late Dr. Wood died, an active canvas for his appointments was begun, and on the morning after, one bailie was startled, it is said, from his morning dreams by the rattle of three doctors' carriage at his door. We hear that this conduct has drawn from the bailie and councillors remarks not altogether laudatory to the profession, and in some cases a by no means concealed sneer is levelled at our "delicate sensibilities."

HOSPITAL ATTENDANCE IN EDINBURGH.—At one time it was required by the infirmary authorities that students taking out their hospital ticket should "sign the album" at stated periods; and so that there should be no mistake, the names of the month in which it was necessary to sign the album were printed on the back of the ticket. This law, which at least required the attendance of the student at the "office" of the Infirmary, has been abolished, so that now not even this slight guarantee that the student was, at times, close to the Infirmary, can be afforded. It is well known that a large number of the students seldom attended the Infirmary for any other purpose than to enrol their names, except, perhaps, just before their clinical examinations to get up the cases. In some cases, even this attendance was not made, as there were always "friends" who brought a good account of the probable test cases likely to be placed before the young M.B., or L.R.C.S., L.R.C.P. Something ought to be done to require a more prolonged attendance on the wards than is merely required to get up the facts and fancies of "Heart Balfour," or the theories of Drs. Muirhead and Brackenbridge, on the action of Sulphate of Copper, and their ideas on Disseminated Cerebro-spinal Sclerosis, preparatory to being examined on them.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—PROPOSED NEW FELLOWSHIP LAWS.—By a majority of two, the Fellows have decided to continue the sale of the Fellowship under the old regulations. At the meeting held last Thursday, Dr. Dunsmure proposed that the Committee on the new laws should be thanked for their trouble, and that no action be taken on the report at present. This was seconded by Professor Spence. The chief argument of the proposer of the motion was that, as legislation was imminent, the College should await the result of such legislation, and not put "their

house in order," as suggested by one Fellow. In other words, it were better for the College to commit suicide than be killed by the Government. This profound argument was ably seconded by Professor Spence, the new representative of the College in the General Medical Council, who thus foreshadowed the obstructive intention of the College to reform in any shape. In opposition to this, Mr. Chiene proposed as an amendment, that the time had *now* arrived to make some alteration in the laws relating to admission to the Fellowship. This was supported by Professor Turner, Dr. Argyle Robertson, and others. On being put to the vote, the motion was carried by two, as we have before stated. About 40 out of 463 Fellows were present, many well-known Edinburgh Fellows being conspicuous by their absence. There is a vague suspicion about, that the sale of the Fellowship may be useful in providing the sinews of war for opposing every attempt at medical reform.

**THE NEW MEMBER OF THE MEDICAL COUNCIL.**—On Thursday last Professor Spence was unanimously elected to represent the College of Surgeons in the Medical Council, the vacancy being caused by the death of Dr. Andrew Wood. At the same meeting the Medical Reform Bills were laid on the table, and the Council, *as usual*, requested to petition against them.

**A VIVISECTION PRAYER MEETING DISTURBED.**—A correspondent informs us that, at an anti-vivisection prayer meeting recently held in Nicolson Street Hall, Edinburgh, and attended by a number of ladies and gentlemen, the end of the hall was taken possession of by some persons, believed to be medical students, who kept up such a constant noise that the business could not, without the greatest difficulty, be proceeded with. In spite of persistent interruptions, singing and prayer were engaged in, and a short address given by the chairman; but as there seemed no appearance of better behaviour on the part of the disturbers of the peace, it was at length found necessary to bring the meeting to a premature close.

**THE ESTABLISHMENT OF A CRECHE FOR EDINBURGH.**—Last week a meeting was held in Edinburgh for the purpose of launching a movement which has been set on foot to provide for the establishment in the districts of West Port, Greenside, and Causewayside of day nurseries for little children, based upon the principle of one in Commercial Road, London, established by Mrs. Hilton, which had been of great benefit to the working classes in the east end of the Metropolis, and was largely patronised. To further this object the chairman submitted the following resolution:—"That, in the opinion of this meeting, it is desirable that several day nurseries should be established in the city for the purpose of providing a home for the day for children of tender years of those mothers who have to go out to work, in order to provide for supporting themselves and families." The chairman further remarked that it had been calculated that a sum of £500 would put the movement on a satisfactory basis, and when the subject was properly brought before the benevolent public in Edinburgh, he was certain the promoters of the movement would receive the amount they required. Dr. James Carmichael, in seconding the motion, thought that Miss Stirling deserved the thanks of the citizens of Edinburgh for having started a movement of this kind. He had been familiar with it from the first, and knew it had done a great deal of good in the Stockbridge district. He had no doubt that if similar nurseries were opened in other parts of the town they would prove of general benefit to the community, and supply a felt want. This motion was also adopted, and the proceedings closed with a vote of thanks to Bailie Colston for presiding.

## Literary Notes and Gossip.

**MR. BRASSY, M.P.**, Civil Lord of the Admiralty, has just furnished a public reference library in his house, at Claremont, Hastings, at a cost of between £2,000 and £3,000.

OUR portly library companion, "Ziemssen's Cyclopædia of the Practice of Medicine," although two years behind hand with the last volume, is yet incomplete. "At the earnest request of many subscribers, an Index volume to the complete work is now being prepared, and will be published shortly at the probable price of one guinea;" so says the publisher's notice.

By the way, we think the American publishers have been hardly dealt with by the Germans. Vols. x. to xvii. of "Ziemssen" were published before vol. ix., which latter volume it was expected would treat of Diseases of the Skin, but various causes have prevented the preparation of this treatise, and considering the uncertainty as to when the volume on "Skin Diseases" will be published in Germany, the work is announced as complete without its Skin.

LEST, however, any subscriber should feel disappointed, the publishers announce that, upon the issue in Germany of the work on "Diseases of the Skin," which will then form a part of "Ziemssen's Cyclopædia," they will at once have it translated, and publish it here as an independent volume; and further, they will present a copy, strongly bound in cloth, to every subscriber of "Ziemssen," who has completed his set by that time. We scarcely know which to feel most sorrow for, the subscribers or the publishers.

We learn that Her Majesty's Government have received a draft of an International Copyright Convention from the United States Government. It is not exactly a direct proposal, but rather a basis for further discussion and negotiation. It proposes that an English author shall only have his book protected in the States on condition that the American edition be manufactured as well as published in that country.

IN order to consider the before-mentioned draft, conferences have been held in London, in the rooms of the Royal Asiatic Society, at the latter of which, the following amendment to the American proposals was unanimously carried:—That the time within which the British author must intimate his intention of publishing in the United States should be extended from three months to twelve. It was further decided to accept the draft as a basis for further negotiations, in order to effect other modifications for the protection of British authors from piracy, especially the clause which insists that an English author must protect his copyright by printing in the United States.

A SOCIETY has been started on the model of the New Sydenham Society, for the purpose of supplying its members with such works, translations or original, as may be deemed essential. The first volume issued is a translation of Hahnemann's "Materia Medica Pura." It is this rather than his Organon, that is the foundation of the homoeopathic system of practice; and those anxious to investigate the subject will now have an opportunity of judging how far the remedies in use at the present day are plagiarised from Hahnemann, as the disciples of his school loudly boast they are. Dr. Hayward, of 117 Grove Street, Liverpool, is the Hon. Sec.; and Mr. Holden, of Liverpool, bookseller to the Society.

"A LONG-felt want" has just been supplied in India by the publication of the first number of the *Medical Observer*. From our knowledge of the excellence and thoroughness of the work done by the *Indian Medical Gazette*, we are surprised that a medical journalistic want should be a long-felt one in India; and without wishing to discourage the bantling which is to do so much, we doubt its *raison d'être*. When some few years since the established medical journal of that country was in danger of collapse for want of adequate support, it was pleaded as a reason why medical men took so little interest in it, that their tenure of any post was so uncertain, and their whereabouts so indefinite, as to be a source of discouragement to literary work. Where, then, does the long-felt want come in? India is what she was when this plea was put in, and medical men are moved about in the same unceremonious manner, *mais nous verrons*.

We have received two Directories which are of interest to the profession, viz., *Street's Indian and Colonial Directory*, and the *Medical Directory for Ireland*. In these peripatetic times, when our Colonies and India in particular, are commonly traversed by, and become the homes of medical men from the old country, information therefrom is of considerable value to those contemplating leaving these shores. To such, we would say, take a look at *Street's Indian and Colonial Directory for 1881*. Of the other, the *Medical Directory for Ireland*, little need be said in these columns. Its present issue is as full and correct as those of the past, not the least valuable section of it being that which contains all the Acts of Parliament, relating, not only to Ireland, but to the profession at large. As a library book of reference, it is worth more than the few shillings charged for it for this section alone, beside other matters of interest.

ACCORDING to a publication which has just seen the light, "*Hubbard's Newspaper Directory of the World*," we learn that there are 30,000 newspapers and periodicals published in the world; of these, 9,000 are published in the United States, 5,000 in the German Empire, 3,000 in Great Britain and Ireland, 2,500 in France, the balance being found in other countries in smaller proportions. Of course it is impossible that a compiler of a work of this kind can be even approximately correct in estimating the circulation of journals so widely distributed, but many of his figures are useful for comparison, and interesting in the aggregate. For instance, he computes (the editor is an American), that although Great Britain boasts but 3,000 journals, yet 1,734,841,956 copies of each issue are printed, as against 1,886,478,592 copies of the 9,000 American presses; to put it in another way, an average of three times the number of copies of each newspaper is printed in this country greater than in the United States.

THE Society for Promoting Christian Knowledge has just published Mr. Frank Buckland's last work, which was completed on the 17th December, two days before his death. It is entitled, "*Natural History of British Fishes*," and contains some strong arguments against the doctrine of "Evolution," propounded some years ago by Dr. Darwin.

"LECTURES on Domestic Hygiene and Home-Nursing," by Dr. Lionel A. Weatherley is an admirable little work, excellently adapted to convey just that degree and kind of information, of which mothers and sisters stand in need. Dr. Weatherley's style is especially clear and concise; the directions are simple, and easily carried out, the comfort of the invalid is insisted on, and due regard paid to the ventilating and cleansing arrangements essential to sick-room management. As a popular guide to home-nursing, the little manual is deserving of the highest praise.

A SMALL work on "*Domestic Plumbing and Water Service*," by Mr. William White, F.S.A., is the title of a handy guide to the details of home-work in connection with drains and pipes. The constant troubles associated with water-closets, and waste-pipes, are described in it, and the method of obviating them, explained in a way that all who run may read. Ventilation traps form a very necessary adjunct to properly built establishments, but are not often enough insisted on by occupants of houses. There is no excuse for the omission of these necessary safeguards, now that the necessity for them is so plainly shown, and their provision, at small cost, made possible. It is to be hoped Mr. White's counsels may be widely adopted.

The *Edinburgh University Quarterly Magazine*. We have seen a copy of this new venture, and wish it all the success that the promoters can themselves desire. There cannot be a doubt but that there is room for such a publication; the only matter of surprise being that there has not been one before. Surely among the large number of students flocking to Edinburgh there must be some literary talent that only wants an opportunity to make itself known. The Athletic Club are the sponsors of the "wee bairn," and judging from its first number, there is no want of muscular development. Some of the articles show a slight want of literary experience, but it would be ungenerous to criticise too severely this, the first attempt.

AMONGST the scientific and educational serials, which aim a helping hand occasionally, we would draw the atten-

tion of our readers to Messrs. Cassell's monthlies. "*The Countries of the World*," for the month of February pursues through the African tribes, the Barbary States, the West Coast Settlements, Tripoli, Tunis, Algeria, &c., &c., the descriptive history of this great, and comparatively, unknown continent, which was commenced in the issue for the past month. The first page of the number is faced by a full-page illustration of a Moorish warrior, and the thirty-two pages of matter, which the number contains, are garnished by no less than thirteen admirable engravings. Probably the most interesting chapter to English readers is the last which refers to Ashanti, and to which is attached an illustration of Coomassie, which cannot fail to attract the curiosity of those who recall the events of a few years past. In the editing of a popular serial like this, it is no easy task to keep clear of dry historic and statistical details, and, at the same time, supply the reader with facts having educational value, and the current number of the "*Countries of the World*," shows the skill with which its editor, Dr. Robert Brown, has effected this object.

IN "*Science for All*," the final chapter of the last issue on Earthquakes, is completed. Mr. Denning, F.R.A.S., presents his readers with an attractive and not over-elaborate account of the planet Saturn and his Moon; the most interesting member, as we think, of the numerous family of our common parent and patron, the Sun. The palæontologist is presented with his share of the work by Mr. Lapworth, of Madras College, who writes on "*Old Sea Pens*," meaning, thereby, the fossil zoophytes, called graptolites. The natural history student may, from this interesting chapter, learn a good deal of what is commonly known about "*Sea Pens*." This chapter is followed by one, from the pen of Mr. Jeffrey Bell, Professor of Comparative Anatomy in King's College, upon "*Digestion*." All, or most that it contains, has, or ought to have been, already learned by the average medical reader, but it is not likely that the anatomy and physiology of the digestive system have ever been found so well-packed into an article readable by the general public. Lastly, the February issue of "*Science for All*," opens up the physics of "*a piece of paraffin*," which goes over into the next issue, and promises to be instructive, as well as amusing. The number of this serial now under review, is decidedly over average merit, and, for its purpose, cannot be improved upon.

PART 50 of the "*Practical Dictionary of Mechanics*," covers all the ground between "*Ore*" and "*Pan*." From the endless diversity of its contents, it is obviously incapable of being criticised, even by a mechanical engineer, still less by the reviewer of a medical journal. Illustrations innumerable, and letter-press exhaustive in its description of every conceivable mechanical device, whose name comes within the range of the letter O and P, are the contents of this number; many of these devices being for surgical uses.

THE serials of Messrs. Cassell are, in our view, without equal as popular educators. High science pedants may sneer at these works as being calculated to communicate the "*little knowledge*" which, we are told, is "*a dangerous thing*." Let them sneer. To the busy middle-class student, books of this class are indispensable, and it is by their means that the ranks of the high-science men themselves are recruited. Therefore, we say that the public owes much to firms like that of Cassell and Co., who devote their attention and their capital to the dissemination of meritorious educational works, instead of the noisome rubbish with which the fiction market is flooded by some other houses.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, January 5th:—"Ziemssen's Cyclopædia of the Practice of Medicine," vol. ix. "*Hernia Strangulated and Reducible*," by J. H. Warren, M.D. "*The Retro-spect of Medicine*," vol. lxxii. Edited by Dra. W. and J. Braithwaite. "*A Plea for Mercy to Animals*," by James Macaulay, M.D. "*Statistical Report of the Health of the Navy for 1879*," "*Anatomy of the Arteries of the Human Body*," by J. Hatch Power (3rd edition), by W. Thomson, F.R.C.S., and B. W. Richardson, F.R.C.S. "*Carpenter's Human Physiology*," Edited by Henry Power, F.R.C.S. (9th edit.) "*Dissection of the Human Body*," by J. Cleland, M.D. (2nd edit.) "*Student's Guide to the Diseases of Woman*," by A. L. Gilabin, M.D. (2nd edit.) "*Diseases of the Bladder*," by W. J. Coulson, F.R.C.S. (6th edit.) "*The Ventilation of Dwelling Houses*."

By F. Edwards (2nd edit.) "The Irish Medical Directory for 1881." "A Treatise on Diseases of the Joints." By R. Barwell, F.R.C.S. (2nd edit.) "St. Bartholomew's Hospital Reports," vol. xvi. "Lewis's Medical and Scientific Library Catalogue." "A Manual of Ophthalmoscopy." By Le Dr. Dagnestet. Translated by C. S. Jeaffreson, F.R.C.S. "Food for the Invalid." By J. Milner Fothergill, M.D. "Aids to Diagnosis" (Semeiological). By J. Milner Fothergill, M.D. "Aids to Diagnosis" (Physical). By J. C. Thorowgood, M.D. "Aids to Rational Therapeutics." By J. Milner Fothergill, M.D. "Surgical Cases." By W. Newman, M.D. "The Treatment of Electrolysis." By W. Newman, M.D. "Syphilis and Marriage." By Alfred Fournier, M.D. Translated by A. Lingard, M.R.C.S. "Healthy Homes." By Stanley Haynes, M.D. "A Guide to Therapeutics" (2nd edit.) By Robert Farquharson, M.D.

as I have no doubt, it will be in the future. Without wishing to say one word against the two gentlemen opposed to me, I may be permitted to state that I believe I had the strongest claims to the appointment. I had performed the duties during the Masterships of Drs. Denham and Johnston, and during part of the time of the present Master. The late Dr. Hudson was aware of this, and often thanked

Your obedient servant,

HENRY KENNEDY.

[We have never had the least intention to question Dr. Kennedy's claim or fitness for the office of Consulting Physician to the Rotundo. We simply asserted the view that the Master who is to consult ought to have a pre-eminent right to express an opinion as to the person who is to be consulted. We think that the profession generally will concur with us in this view.—Ed. M. P. & C.]

## Correspondence.

### VISITATION OF EXAMINATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 9th inst., under the heading "Visitation of Examinations," you announce the appointment of three surgeons to visit, on behalf of the Medical Council, the examinations of the College of Surgeons of the three divisions of the kingdom, and while justly applauding the selection made, you most unjustly cast an unmerited slur upon the work done by those who visited and reported upon these examinations upon the last occasion. You express a hope that the gentlemen now appointed "will not inflict upon the profession the series of polite platitudes which formed the staple of the reports of the first visitors appointed by the Medical Council."

I was one of those visitors, and reported with Dr. Fleming, of Glasgow, upon the 1st professional examination of the College of Surgeons in England, and upon the pass examination of the College of Physicians. I now call upon you either to prove the truth of your flippant assertion as it applies to the report made by us, or to withdraw it.

I have the honour to be, Sir,

Your obedient servant,

JOHN K. BARTON.

24 Lower Fitzwilliam Street, Dublin.  
February 14th.

[Our "flippant" assertion was perfectly accurate, nor need Dr. Barton feel offended by it, seeing it does not refer either to him or his co-visitors. The "first" visitation made by the Medical Council was in the year 1866. It was performed by the members of the Council themselves without extraneous aid, and resulted, as we said, in a volume of polite platitudes which did not advance examination reform in the least degree, and was not worth the money paid for it. The visitation at which Dr. Barton assisted was made in 1874, and was conducted mostly by visitors outside the Medical Council. Consequently it was, in most cases, honest and outspoken, and produced an excellent effect upon the examinations of the licensing bodies which were visited. We think that Dr. Barton might as well have acquainted himself with these facts before he indulged in the expletive which we have quoted.—Ed. M. P. & C.]

### THE LATE ELECTION AT THE ROTUNDO HOSPITAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A late issue has an article on the recent election at the Hospital. Being one of the candidates on this occasion, will you kindly allow me to make one or two remarks.

The writer of the article, or rather articles, for there was one in both the *British Medical Journal*, and also yours (and evidently written by the same party), seems to think this appointment of consulting physician should be in the hands of the Master *pro tem*. I cannot accept this view of the matter, nor do I see why the appointment should be in the hands of the Governor, as it was on the last occasion, and,

### "TO TERMINATE CHLOROFORM NARCOSIS."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to note in issue of the *Medical Press and Circular* of February 9, 1881, page 121, calling attention to a method practised by Schirmer, by which he has "often succeeded in producing inspiratory movements when other means failed," the following cases may be of interest as confirming his observations, and as showing how rapidly and effectually irritation of the nasal mucous membrane restores consciousness in profound alcoholic narcosis.

The idea of restoring consciousness by stimulating the nasal branches of the fifth nerve is not a novel one; the inhalation of the vapour of ammonia is an everyday practice, and holding burning feathers, &c., under the nose, is a very common popular remedy. The novelty of the method, however, consists in the application of the irritant directly to the mucous membrane, and it is available and effective in cases where either respiration is temporarily suspended, or too feeble for inhalation to be of any service. On the other hand, it avoids the danger of exciting bronchial irritation, which may arise from the vapour of strong ammonia, and it is much more rapid and decisive in its action.

In 1873 I was asked by the police to go to the barracks, and see a respectable farmer, whom they feared was dying. The history of the occurrence I received was that he had been drinking heavily all day, and on leaving the last public house he had visited, he fell insensible in the street.

I found him stretched before the fire in the police barracks in a state of profound coma. Sensation abolished; he apparently did not feel any irritation applied to the skin; the pupils did not respond to the light; the conjunctivae was insensible when touched; respiratory movements very feeble; extremities cold and livid. I sent for a stomach pump, and whilst waiting, tried to administer a strong dose of *spt. ammon. aromat.* in water. I had to give it in teaspoonful doses, and the first spoonful ran down to the back of the throat without any apparent effort to swallow. As I was about administering a second, a sub-constable, who was watching my proceedings with great interest, accidentally hit my elbow, and the result was, that instead of going into my patient's mouth, the contents of the spoon was discharged fairly into his nostrils. Two or three deep inspirations followed almost immediately, and were soon succeeded by one or two hearty sneezes. I then got a feather, and dipping it in the ammoniacal solution, passed it down his nose. There was no doubt he felt it, for he now began to move and sneeze again, rubbed his nose energetically, and sat him up. By the time the stomach-pump arrived he was quite lively, and a vigorous fit of vomiting having ejected a considerable quantity of liquor, he pronounced himself quite well.

The second case was somewhat similar. A young man, having been drinking all day, got up on his car, and after driving about a couple of hundred yards, his servant boy found him lying insensible across the wheel. Alarmed at his appearance, he had him brought into a house, where I found him very much in the same condition as the former case.

I at once applied a strong solution of aromatic spirits of ammonia to the entire length of the nasal mucous membrane with most satisfactory results. The only difference between this and Case 1, was that the effect was not at first so marked. After the first application, the inspiration

became deeper and stronger, and there was evidence of returning consciousness; but in a minute or two he evidently was relapsing into a comatose condition. The feather in the other nostril made him much more active, and produced a rattling sneeze, and a vigorous rubbing of the nose. A few minutes observation showed a third application was necessary, and it was most effectual. It was rewarded by a most emphatic objurgation. The patient sat up, and sneezed violently, and then got rid of his cargo of liquor, and in such an energetic fashion, that distant observation was a very necessary precaution for those around him.

Since that time I have had a few more opportunities of testing the practice in somewhat similar cases, and have invariably found it most successful. I have had no cases of chloroform narcosis requiring interference, but I think that the same procedure would be serviceable in such cases.

I am, yours, &c.,

R. V. KINKEAD, M.D. Dub., &c.

Galway.

## Obituary.

### PROFESSOR CRYAN, F.K.Q.C.P.I.

ON last Thursday morning this lamented gentleman died after a very brief illness, at his residence, Rutland Square, and at the comparatively early age of fifty-four years. He was born in Boyle in the county of Roscommon in the year 1825; and, on obtaining his professional qualifications, was appointed lecturer on anatomy and physiology in the Carmichael School of Medicine, then attached to the Hospital of the House of Industry. He was a most successful lecturer and private teacher, and the reputation he popularly thus acquired secured his appointment to the physicianship of the North City Dispensary and to the Cholera Hospital. In all these capacities he proved equally successful; and on the foundation of the medical school of the Catholic University in 1855, he was appointed Professor of Anatomy and Physiology, and was subsequently promoted from the dispensary to the physicianship of St. Vincent's Hospital, which, along with the University appointment, he held up to the period of his demise. He was a Fellow of the King and Queen's College of Physicians and a member of the Royal Irish Academy, and of most of our medical and scientific associations. Professor Cryan was an untiring student; and nobody ever kept up more closely to the ever-advancing literature of the profession. He was wealthy; and this circumstance, along with a natural quiet unassuming demeanour, prevented his making that figure before the public eye which a more pushing man would have done. His merits were, however, thoroughly appreciated by his professional colleagues, and his success as a hospital and school teacher was very distinguished. No one was ever more respected or beloved by the students; and on the day of his funeral upwards of one hundred of his hospital school class each wearing crape on his arm, walked in procession after the hearse, and on arriving at the cemetery carried his coffin on their shoulders and with their own hands laid it in the grave. In fact, of Dr. Cryan it may be said that he had many attached friends and not a single enemy; and that he will be long and deeply regretted.

### PROFESSOR SANDERS, M.D., F.R.C.P., OF EDINBURGH.

SCARCELY has the grave closed over Andrew Wood than the profession in Edinburgh has again to lament the loss of another of its distinguished members in the person of Dr. Wm. Rutherford Sanders, Professor of Pathology in the University, whose death occurred on Friday last at his residence in Charlotte Square, from an apoplectic attack. It appears that in September last on returning, in apparently robust health and spirits, from his autumnal holiday spent at Urral, in Perthshire, Dr. Sanders was suddenly seized with paralysis of one side of the body, accompanied by complete loss of speech. Since then he had to a certain extent recovered, and was able for the last two months to be in his drawing-room during the greater part of each day. On Thursday forenoon, however, he was again suddenly struck down by

an apoplectic seizure, became quite unconscious and remained so until his death on the morning following.

From the *Scotsman* we learn that Professor Sanders was born in Edinburgh in January, 1828, his father being at that time a well-known physician in that city. His education was obtained at our High School, and subsequently at Montpellier, in France, where he obtained the degree of Bachelier des Lettres in 1844. Choosing medicine as his profession, he entered Edinburgh University on his return to Scotland; and after the usual courses of study took his degree of Doctor in 1849, at the same time gaining a gold medal for his thesis "On the Anatomy of the Spleen." After passing some time as clinical clerk in the Royal Infirmary, Dr. Sanders went abroad, and spent the two following years in Paris and Heidelberg, especially studying microscopical anatomy under Henlé. On his return to his native city he acted as interim pathologist to that great hospital during a part of 1852. He held the important office of Conservator of the Museum of the Royal College of Surgeons for seventeen years, and lectured on physiology with great acceptance in the Extra-Academical Medical School for fourteen years. In 1860, he was appointed physician to the Royal Infirmary; and in 1869 succeeded the late Professor Henderson, on his resigning the Chair of Pathology in the University.

Dr. Sanders's mind was of a high order—clear, decisive, critical and analytical. He did not write much; but what he did write, in the form of papers in the Transactions of various societies (including the Medico-Chirurgical, of which he was President) and monographs, chiefly on physiological or pathological subjects, in the medical journals, was excellent work of its kind, specially remarkable for that precision and accuracy of statement which were the natural outcome of an intellect lucid and well balanced. As a physician, he excelled in diagnosis, and, after the death of Dr. Begbie, he may be said to have stepped into the foremost position in Edinburgh as regarded consulting practice. As a teacher he was almost unrivalled; and in his class-room each student seemed more attentive than his neighbour. There was here no noise or idle horse-play; all, without exception, apparently considered the words which dropped from the Professor's lips as too valuable to lose.

Dr. Sanders seemed to have no enemies, and his place in the affectionate regard of all circles where he was known will be hard indeed to fill. By his premature death the Edinburgh University loses one of its brightest ornaments, and the news of it will be received with deep regret all over the kingdom, wherever his students have gone.

Dr. Sanders has left a widow, with a family of two sons and three daughters.

### DR. EDWARD PEELE OF DUBLIN.

THE very serious illness of Dr. Peele, which we noticed in this journal last week, terminated fatally, we regret to say, on last Friday morning, and on Monday his remains were laid in the grave followed by very many sorrowing friends. It is just twenty years since Edward Peele came to Dublin. The son of a gentleman residing in the county of Durham, he had been at first devoted to the profession of music, and it was upon his appointment to the office of Vicar-Choral of St. Patrick's Cathedral that he first took up his residence in Dublin. Before many years had passed he decided to enter upon the study of the medical profession, and that decision he acted upon with characteristic steadiness of purpose and zeal, permitting neither avocations nor pleasure to interfere with his determination to educate himself thoroughly and to achieve professional success if possible.

In 1872, having studied at the School of the College of Surgeons, and at the Adelaide and Stevens's Hospitals, he became a licentiate of the College of Physicians, and, in the succeeding year he obtained the Letters Testimonial of his Surgical College. His first step in professional life was his appointment as Demonstrator of Anatomy in the College of Surgeons, upon which his appointment as Medical Officer to the High Street (South Dublin) Dispensary shortly followed. About two years since he was chosen Physician to the Hospital for Incurables, and was also associated with the Hospital for Diseases of the Throat and Ear in York Street, Dublin, and, as Visiting Physician, with the Coombe Lying-in-Hospital. By his untimely death all these offices become vacant.

Dr. Peele's contributions to medical literature were not numerous, his time having not yet arrived for the publication of a work of prolonged experience. To the *Dublin Hospital Gazette* he contributed, early in his career, cases of Pleuritic Effusion, of Paracentesis Moracis, of Paraplegia complicated with Hematuria, and of Caries of the Vertebra, and his last contribution was one to the *Dublin Medical Journal*, on the Treatment of Tetanus by chloral hydrate. Dr. Peele was stricken with his fatal illness on Thursday, the 3rd inst.

He had been hard worked in his attendance on several cases of typhoid amongst his poor patients, and, after the usual premonitory symptoms, he developed the disease in its most virulent form, the most alarming circumstance of his case being an intermittent and very weak pulse, which was noticeable on the third day of the fever and continued all through to the end. By the unwearied exertions of his physicians, he was carried—as it seemed—through the most dangerous period of the disease, and on Thursday last, the symptoms assumed a more favourable appearance, but, unfortunately, the critical change was not fully established, and he sank.

Considering the very brief career of Dr. Peele, it may be truly said that no more successful or popular member of the profession has lived in Dublin of recent years. His geniality of manner, strict uprightness of feeling and of action, and thorough business capacity would—we doubt not—have won for him a high popularity with the public at large. As a member of the Executive Committee of the Irish Medical Association he manifested unusual administrative talent, and, thus possessing all the attributes of a successful physician his loss is the more deeply regretted.

## NOTICES TO CORRESPONDENTS.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

**SPECIAL NOTICE TO SUBSCRIBERS.**—The Publishers respectfully remind Subscribers that subscriptions for the past year are now due, and should be remitted for England and Colonies to the London office, for Ireland to the Dublin office, and for Scotland to the Edinburgh office.

**MR. J. H.**—In the present crowded state of our columns your letter is much too long to secure insertion at least for the next three months.

**MR. HAMILTON CRAIGIE.**—Report received.

**DR. REES PHILLIPS** will please receive our thanks.

**MR. VITALI.**—Some time next month.

**A FIRST YEARS' MAN.**—You cannot adopt a wiser course.

**DR. WILMOT.**—The *American Journal of the Medical Sciences* and the *Westminster Review*.

**MEDICUS.**—Your letter is unavoidably held over for want of space.

**DR. PALFREY.**—We hope to be able to devote space to your interesting case in our next.

**DR. McCULLAGH.**—See reply to Medicus.

**DR. G.**—The occurrence is most unfortunate, and deserves the sympathy of the entire profession.

**MR. SELWYN.**—It is contrary to our custom to recommend any practitioner in these columns.

**OUR POOR-LAW SUPPLEMENT.**—In consequence of the unusual demand made this week on our advertisement pages, we are compelled to hold over the customary Supplement of Poor-law Medical Intelligence until our next.

**DR. CARLO RUOTA (Padua).**—Sorry we cannot further add to our already too large Exchange List.

**ANXIOUS.**—Legally, your qualifications do not entitle you to the prefix of "Dr.;" but, by a too common, and to our minds unfortunate, custom, it has become so usual of late that no notice is taken of it.

### PAYMENT OF SUBSTITUTES FOR DISPENSARIES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—When a dispensary medical officer obtains leave of absence from the committee, and his substitute appointed by the committee, according to Article 22 of the Dispensary Rules, are the Board of Guardians empowered to make conditions and "resolve that they will sanction the leave of absence to the medical officer on condition that he will pay the substitute."

I cannot find that they are authorised to interfere with the medical officer's appointment or leave, or to make conditions with him, and am anxious to have the benefit of your opinion.

Yours, &c.

QUEST.

\*. If the medical officer falls sick he has only to notify the fact to the hon. sec. of his committee and recommend a duly-qualified substitute. The committee may, or may not, appoint the person named, and be foolish enough to do the work without a clear agreement as

to pay, they may eventually refuse any remuneration. But they cannot curtail the medical officer's salary by one farthing, or make him pay a sixpence towards salary of his *locum tenens*.—Ed.]

**DATE COFFEE.**—There is considerable stir in the commercial world on the subject of Date Coffee, and the Shares of the Company which introduced the article have gone up with a bound. As an item of food and dietetics, our opinion has been asked as to its suitability for invalids and for persons of weak digestion. As, however, it is our invariable rule not to express this without first practically testing the merits of an article, we have handed samples of the Date Coffee to an analyst of position, and shall report thereon in our next. Of course, we cannot be expected to pass an opinion on the value of the Company's Shares as a commercial speculation. The prospectus of the German Date Coffee Company will be found in our advertisement pages, of which some of our readers can doubtless form a better judgment than ourselves.

**HUMERIAN SOCIETY.**—On Wednesday, Feb. 23, at 8 p.m., Introductory Address by the President.—Mr. T. E. Adams, "On Diphtheritic Ophthalmia."—Mr. G. T. B. Stevens, "On a Case of Erysipelas of the Scrotum and Penis."

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—Wednesday, Feb. 23, at 4 p.m., Prof. W. K. Parker, "On the Structure of the Skeleton in the Sauroptera."

**SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.**—Wednesday, Feb. 23, Mr. W. H. Procco, "On Recent Advances in Electric Lighting."

**CLINICAL SOCIETY OF LONDON.**—Feb. 25, at 8 p.m., Dr. Hilton Fagge, "On a Case of Paralysis due to Partial Disease of the Nuclei of the Motor Roots of the Fifth Nerve."—Mr. Teale (Scarborough), "On a Case of Quiescent Scirrhus."—Dr. Crocker, "On Cases of Erythema Iris."—Dr. F. Taylor, "On Cases of Pemphigus and Herpes Iris."

**HARVEIAN SOCIETY OF LONDON.**—Thursday, March 3, at 8.30 p.m., Mr. Osman Vincent, "On Cases of Lumbar Abscess treated by Sulphurous Acid."—Mr. T. Robinson, "On Nocturnal Incontinence of Urine."

### VACANCIES.

Bath Royal United Hospital.—Resident Medical Officer. Salary, £100, with board. Application to the Secretary before March 11.

Brighton and Hove Lying-in Hospital.—Surgeon. Honorarium. Applications to the Secretary, 76 West Street, Brighton, before March 1.

Dublin Fever Hospital.—Resident Medical Pupil. Applications to the Chairman of Committee before March 2. (See Advt.)

Glasgow University.—Examinerships in Medicine: 1. Physiology. 2. Clinical Medicine. 3. Clinical Surgery. Fees attached to each office, £40. Applications to Dr. Kirkwood, 145 West George Street, before March 15.

Halifax Infirmary.—House Surgeon. Salary commencing at £37, with board. Applications to the Senior Physician by Feb. 24.

Kent and Canterbury Hospital.—House Surgeon. Salary commencing at £80, with board. Applications to the Secretary at Canterbury before March 25.

Portsmouth Royal Hospital.—House Surgeon. Salary, £100, with board. Applications to the Chairman of Committee before Feb. 23.

West Norfolk Hospital.—House Surgeon. Salary, £100, with board. Applications to the Secretary at Lynn before March 4.

### APPOINTMENTS.

CHESBROUGH, H. H., M.D., Consulting Physician to the Blackburn and East Lancashire Infirmary, on resigning as Physician.

JAMES, C. E., A.B., M.B. T.C.D., L.R.C.S.I., Second Surgeon to the Kilkenny County Infirmary.

MURPHY, Dr. J. J., Medical Officer to the Dublin City Commercial Club.

RITCHIE, J., M.B., M.C., F.R.C.S.E., Surgeon to George Heriot's Hospital, Edinburgh, vice Dr. Andrew Wood, deceased.

### Births.

BLACKETT.—Feb. 15, at Wangford, Suffolk, the wife of Edward R. Blackett, M.D., of a daughter.

COLLINGRIDGE.—Feb. 15, at Belwood, Mayow Road, Forest Hill, S.E., the wife of W. Collingridge, M.B. Cantab., of a daughter.

SHUTTLEWORTH.—Feb. 17, at Lancaster, the wife of G. R. Shuttleworth, M.D., Medical Superintendent of the Royal Albert Asylum, of a daughter.

### Deaths.

BARTLEY.—Feb. 6, at St. Helier's, Jersey, John Matze Bartley, M.D., A.M.D. (retired), aged 93.

BIGSBY.—Feb. 10, at Gloucester Place, Portman Square, W., John J. Bigsby, M.D., F.R.S., in his 89th year.

BRADY.—Feb. 13, at La Chosa, Rathrig, Maria Louisa, the wife of D. F. Brady, J.P., M.D.

CRESSY.—Feb. 14, at Bedford House, Gravesend, Theodore G. Cressy, M.R.C.S.F., in his 61st year.

CRAYN.—At 54 Rutland Square, Dublin, Robert Crayn, F.R.C.S.P., M.R.I.A., Physician to St. Vincent's Hospital, Prof. of Anatomy and Physiology, Catholic University.

FARLE.—Feb. 18, at his residence, 41 Lower Baggot Street, Dublin, of fever, contracted in the discharge of his duty, Dr. Edward Peela.

**MEDICAL.**—Wanted a Competent Person to conduct a Medical Establishment in a Provincial Town. Candidates must possess a Diploma in Medicine and Surgery, or the Licence of the Apothecaries' Hall. Salary not so much an object as a properly qualified person. None need apply whose testimonials will not bear the strictest investigation. A Protestant preferred. Applications, accompanied with Testimonials, to be forwarded to M.D., 59 Victoria Street, Belfast.

## Original Communications.

### A CASE OF VESICO-VAGINAL FISTULA WHICH WAS SPONTANEOUSLY CURED.

By JAMES PALFREY,

Obstetric Physician to, and Lecturer on Obstetrics and Disease of Women at the London Hospital.

I HAVE for many years held the opinion, and have acted upon it, that our knowledge is not advanced, or our art benefited by the publication of solitary cases, no matter how rare such cases may prove to be, but to this rule undoubtedly exceptions do now and then occur, cases I mean, which either run an unusual course, or terminate in an unusual manner, the consideration of the progress or termination of which cases carries to our minds a useful, sometimes a valuable, lesson. Such a case has just passed under my observation, and because I have derived a lesson of considerable value, I think, by making public the details, I may possibly be useful to my brethren.

The facts then first, and, subsequently, two or three comments that arise out of the facts.

On the 10th of August last, I was requested by Dr. Gage Fleming, of Thornton Heath, to see with him Mrs. X. Y., residing in the neighbourhood of Croydon. The particulars of the case he gave me were, that his patient was 32 years of age; married eight years; recently delivered of her first child, never having previously been pregnant. That after being in labour twelve hours, she became a good deal exhausted, that some signs of commencing inertia becoming manifested, he delivered her with the long forceps. After delivery she apparently made a good recovery, until the 17th day, when suddenly a gush of urine made it only too clear that she was the subject of a urinary fistula.

At my visit an examination disclosed the following state of affairs:—One inch below the cervix I found an elliptical-shaped opening in the vaginal wall and base of the bladder, which very readily admitted my index finger, and which

would almost have admitted a second finger, so extensive was the lesion, a catheter passed into the bladder by the urethra being made to pass into the fistula, gave us, with the aid of a duck-bill speculum, a good view of the whole opening.

I found a severe croupous vaginitis of both walls, from the continual contact of urine with these tissues, and an erythematous inflammation of the external genitals, resulting from the same cause; for at the date of my visit the fistula had been in existence some little time. The general condition of the patient was not good, the continual irritation was telling on her blood state, she was anæmic, pale, and feeble, and although described to me as having previously been a particularly healthy woman in all respects, her appearance, at the time of my visit, hardly conveyed the same impression to my mind. Looking at all the facts as they presented themselves to me, the deteriorated health of the woman, the inflamed state of the mucous membrane of the vagina, and the extensive opening itself, I advised that the operation, which, I believed, would certainly be necessary in her case, should be postponed; that she should be removed to Walmer, that every three or four hours the warm vaginal douche should be freely used, and that each simple douche should be followed by a medicated one of carbolised water, that some firm doses of quinine should be given her twice daily, and that she should be put on a tolerably generous diet. These measures, I hoped, would result in the improvement of her general and local conditions, and then I suggested to her that on my return to my hospital duty, at the expiration of my usual autumnal holiday, that she should come into hospital, that I might operate upon her, Dr. Fleming having made it clear to me that it would not be possible, in her own home, to surround her with the precautions necessary to ensure success.

To these various suggestions, Dr. Fleming, and the patient, readily assented, and the next day she was removed to Walmer, and placed under the care of Dr. Mason, of that place, and he, in the kindest manner, also carried out the above-named suggestions as to treatment.

Precisely as arranged, on paying my first visit to the Hospital on my return to duty on the 21st of October,

Mrs. X. Y. was awaiting me, and at once met me with the exclamation, "Oh Sir, I have come that you may see me, but I shall not require to be taken into the hospital, for I ceased to dribble three weeks ago, and I can now hold my water a long time." Smiling incredulously, I requested her to lie down, that I might examine her; and only too surely the patient had accurately described the state of matters, for I found just in front of the cervix a considerable puckering, and a well-defined star-shaped cicatrix, the vaginal wall was a good deal shortened, and the uterus itself lower than when I examined it at her home. I conducted my examination with much gentleness, fearing that the newly-made tissue might break down under the pressure of my finger, and being very doubtful as to the permanence of this spontaneous healing, I desired she would come to me again in a month or six weeks. Early in December, accordingly, she again came to me at the hospital, expressing herself as being perfectly well, and her altered and improved aspect carried out fully her own opinion. Another vaginal examination made it clear to all of us present that the cure was complete. The cicatrix I have described was harder, and firmer, and had contracted, shortening, in doing so, the anterior vaginal wall still a little more. I learned that the patient was able to retain her urine for any length of time she desired, and she emptied her bladder without pain, and completely. Fearing even, then, that consolidation of the tissues might not be perfect, I took the opportunity of his presence to advise the husband to postpone for a couple of months longer any return to his marital duties, when he assured me it was too late to give him that advice, for he had occupied his wife's room since the date of her visit to me at the hospital in October, thus affording abundant proof that the healing was complete and sound at that date, or the cicatrix would surely have broken down under such ungentle treatment, and lastly, so far as the details are concerned, in a letter kindly sent me but a few days ago, 11th January, Dr. Fleming informs me that his patient continues "perfectly well." Now it has been my practice for many years to operate on these cases of urinary fistula, as soon as the puerperal period was well over, or as soon as circumstances enabled me to do so, I think I may fairly ask myself the question, how many of the considerable number I have thus treated would have healed spontaneously? It is true, as Scanzoni observes, "that it is excessively rare" (writing of vaginal fistulae), "that they are cured spontaneously;" he had seen three, but he adds, they "were small," whereas, in my own case, the opening would, had I chosen to put my patient to some pain, have admitted two fingers. Then let us inquire, had the treatment any part in bringing about the result? I cannot definitely reply to that question. I can say, however, that notwithstanding the fact that the dribbling continued from the 10th of August until the last days of September, the croupous condition of the vaginal mucous membrane speedily disappeared under the frequent and thorough use of the vaginal douche, containing a solution of carbolic acid, and here let me interpolate a remark concerning this form of irrigation. It will be observed that I have used the term *vaginal douche*, I did so advisedly, and for the reason that many years ago I convinced myself that there exists no more ready and sure means of setting up, and continuing uterine congestion, than by driving with force (such force as most of our patients can, and all our nurses would employ) a stream of water against the vaginal portion of the cervix, and if any who read this statement doubt it, such doubt, I venture to believe, will be removed by holding one of the ordinary firm, elastic vaginal tubes one inch from the palm of the hand for twelve or fifteen minutes, while an attendant woman pumps water upon the exposed surface by means of a Higginson's syringe. The stream to be beneficial must be a gentle stream, and in my hands, Maw's open cistern douche, fitted with a slightly curved vaginal tube, four inches long, perforated to permit of a reverse current, has proved the most useful of all the means I have tried for the purposes of vaginal or uterine irrigation, and I express this opinion,

after a prolonged and extensive use of the instrument, extending over nearly twenty years.

Then a word upon the instructive lesson this case has taught me, and the conviction it has conveyed to my mind, viz., given, a woman whose systemic state is good, and who becomes the subject of this terrible accident, it is certain that, being placed under favourable conditions, hygienic and local, a spontaneous and perfect cure may take place. Lesson: do not too hastily resort to an operation, which, however successful it may eventually prove to be is always tedious, often painful, and entails upon the patient an amount of confinement and restraint which it is not improbable, a further and more careful trial of the expectant method may frequently prove to be unnecessary.

CLINICAL LECTURES  
ON  
INFANTILE PARALYSIS, AND ACUTE ANTERIOR  
POLIO-MYELITIS IN ADULTS. (a)

By THOMAS BUZZARD, M.D., F.R.C.P.,  
Physician to the Hospital for the Paralyzed and Epileptic.

LECTURE II.—(Concluded).

(Corrected from a Shorthand Report.)

PROGNOSIS.

A POINT of great importance in reference to this disease is as to the prognosis. If we look into the nature of the lesion and reflect that we have to do with the destruction of ganglionic cells, bringing about secondarily atrophy of the nerves rising from the anterior cornua; and eventually, though it may be long delayed, degeneration, more or less pronounced, in the muscles to which these nerves go, it is difficult to imagine a more hopeless prospect than must appear likely as regards many of the muscles involved. And so in effect we find it. In a large number of cases the future signifies a progressive deformity which does not shorten existence, but is carried through life with scarcely any amelioration. If the lower extremities be concerned the patient may be only able to stand and walk with the aid of apparatus.

In the last lecture I referred to the case of a lad in whose thigh there still remained, thirteen years after the attack, some evidence of the continued existence of muscular fibre in the fact that there was a slight contraction to the interruption of forty cells of a constant current. In a child seen not long ago in private I found good contraction in the muscles of the thigh and leg to a constant current from thirty-five cells slowly interrupted, two and a-half years after the attack.

These and other examples, however, only illustrate in too many instances the fact that the contractile element is very long lived, even when the muscle is separated from its physiological connection with the spinal cord. But for needs of locomotion we require something more than the existence of an element which is capable of being contracted by an electric or mechanical stimulus. It is necessary that the road by which motor impulses from the brain travel to the muscle should be clear, and if the anterior roots of nerves are atrophied and degenerated the mere persistence of the contractile element of muscle is utterly useless. It is, indeed, the degeneration of the nerve cells and tubules which is the disastrous part of the lesion in this disease. Were it not for the more or less permanent character of these changes in many cases the wasting of the muscle itself which occurs so early would be unimportant. This is, at least for a long time, a simple atrophy, capable of complete repair should the way down from the nervous centres to the

(a) Delivered at the National Hospital for the Paralyzed and Epileptic.

muscles through the ganglionic cells and anterior roots of nerves be opened up.

Charcot points out, from the experiments of Longet, Schiff, Brown-Sequard, and others, that when a nerve has undergone section or partial excision, its peripheral extremity begins from the fifth to the sixth day after the operation to undergo even in its finest ramifications a series of alterations whose ultimate consequence is the disappearance of the medullary cylinder, the axis cylinder persisting according to some but not all observers.

From the fourth day the nerve, M. Vulpian says, is found to have lost the faculty of being excited by the electrical stimulus. As regards the muscular fibre, it does not present at first any modification whatever of the electrical contractility. The decrease, and still more, the utter loss of this property, if they do ensue are never produced until after the lapse of a considerable time and very slowly.

As to the amount of repair of which a nerve fibre which has suffered degenerative changes is capable, we know at present little for certain; but clinical experience would tend to show that after great lapse of time improvement to an unexpected extent may indicate that reparation has been going on. This subject has been admirably discussed by Weir Mitchell in his work on injuries of nerves. The fact is one which should make us hesitate in giving a very unfavourable prognosis even after a long lapse of time.

As a practical contribution to the question of prognosis in the acute anterior polio-myelitis of adult life, I show you a young man who was a patient in this hospital rather more than two years ago. The peculiar interest and importance of his case depend upon the fact that he came under my care, and I have notes of his condition taken by Mr Broster only eleven days after the beginning of his illness. I will read these notes to you now, and then compare them with his present condition.

George B., *æt.* 19, who had followed the occupation of a gardener from the age of 13 years, was admitted into the hospital October 2nd, 1876, on account of loss of power in the left arm and both legs. He is a fair, healthy-looking lad; well built. Quite free from pain as he lies in bed; if he sits up he gets a sharp pain in the lower part of his back which shoots down his legs. Sleeps well; general health good; temperature normal. He can flex the left thigh on the pelvis completely, and rotate it in- and outwards, but no other movement is possible in the left lower extremity. The only movement practicable in the right lower limb is a feeble flexion of the toes. The left arm is weak, especially in the deltoid muscle. The spinal column presents no abnormality, nor is it tender on percussion. When his legs get hot in bed there is an aching pain in them. Muscular sense appears defective in his legs. Touching the soles of his feet produces no reflex movement. The patellar tendon reflex is absent from each leg. There is no rigidity, and he does not suffer from any muscular twitchings. The muscles of the legs are very flaccid and shrunk, and those of the left arm are smaller than those of the right arm. There is no affection of special or common sensation. The heart, lungs, and kidneys show no signs of disease. The bowels are somewhat constipated; the action of the bladder unimpaired.

*Electrical Examination* on the eleventh day of his illness.—There is no reaction to the induced current in any muscles of either of the lower extremities except the vastus internus of the left thigh. The muscles of the left arm react fairly to the same current. To a slowly interrupted voltaic current from fifteen cells of a Störker's battery the muscles of the lower extremities act well.

The patient has been a total abstainer for eight years; he has lived comfortably. There is no history of acute rheumatism or of scarlet fever; and, with the exception of a cold, and an attack of erysipelas in his right leg, he has never had a day's illness until the present attack. There is no history of syphilis.

A grandfather, grandmother, his father, mother, two or

three uncles and aunts, and their cousins, have died of "shortness of breath" and "consumption." His father had heart disease after rheumatic fever. The ages of the above relations at the time of their death varied from twenty to forty-seven. All the family, the patient included, are, or have been, subject to a peculiar attack consisting of giddiness and inability to stand, with mistiness of vision (but without pain in the head, or spectral vision), the whole lasting about five minutes.

A fortnight before admission he had caught a violent cold, from getting very hot at work, and then letting himself cool in a draught. Two days afterwards he complained of very severe pain in the lumbar region, increased by movement. At the same time, there was a throbbing pain down the backs of both legs. His legs twitched, he says, and increased the pain. He suffered from retention of urine, for which a catheter was employed on one occasion only. Next morning he found that he could not stand, and was unable to raise his left arm to his head. There was no loss of speech or impairment of consciousness, and he says that he was not feverish.

Three months after the commencement of his illness his condition was as follows: The right lower extremity is motionless. He can draw up the left leg, but cannot raise the left foot off the bed. The right leg, as he lies, is rotated inwards. There is a wasting of both thighs and legs. Measurement shows that their size is equal. The calves measure  $10\frac{1}{2}$  inches each, the thighs, 11 inches above the knee, 15 inches each. A month later, the right calf measured  $12\frac{1}{2}$  inches, the left  $12\frac{1}{2}$  inches. The right thigh was  $16\frac{1}{2}$  inches, the left 17 inches. There was still no reaction to faradaic currents except in the left quadriceps femoris muscle. In this state he left the hospital. Ten months afterwards, in November, 1879, I saw this lad at his own home. His general health was very good. The left arm was perfectly well, and to all appearance differed in no respect from the right. But he was unable to stand. The right lower limb remained as it was when he left the hospital, there had been no further wasting. He could flex the leg a little on the thigh, but could not extend it. Could adduct with considerable force, but was unable to abduct at all. The patellar tendon reflex in the left leg was present, although small. In the right leg it was quite absent.

This was a twelvemonth ago. He has attended here to-day at my request, and we can now compare his present condition with the last report. He can extend the right leg a little, but he can bring the foot back still better than he can throw it forward; and he can also adduct better than abduct the limb. There is still no patellar tendon reflex in the right thigh. His limbs, as you see, show no wasting; on the contrary, they are large and round; but it is evident that their size greatly depends upon adipose tissue, not muscle. It is sometimes difficult to test the patellar tendon reflex where there is a very fat knee; but I think we may be sure that the reflex is absent here.

I will apply induced currents to the anterior muscles of the left thigh, and you see that, with a strength greater than is needed for normal response, there is a slight contraction in the vastus internus, and a somewhat better contraction in the rectus femoris.

When, instead of the induced, I apply the constant current, there is a contraction on completing the circuit, but  $A S z > K S z$ . The reaction of degeneration is still, therefore, marked.

In the right limb there is no reaction to induced currents, and a very slight contraction when the circuit is closed with either the kathode or the anode on the muscles.

It is to be noted that, although the greatest amount of improvement took place in this patient during the first four or six months of his illness, yet that he has not remained absolutely still during the last twelvemonth. He can now abduct the right knee a little, and extend this leg, which he could not do a year ago.

F. Müller who has lately published the result of some

important researches on this subject, says that all muscles remain completely paralysed in which the faradaic excitability descends perpendicularly from its normal level, and disappears entirely in four or five days. In all the cases in which this excitability *diminishes* only, without disappearing before the twelfth day, and in the cases in which it descends only gradually, motility returns, even after several months. From the complete disappearance of faradaic excitability, or from the reaction of degeneration in the first stage, one can conclude nothing in regard to the curability or incurability of the case. When the contraction A S z alone remains this shows the complete disappearance of the contractile substance.

In infants monoplegia, in adults paralysis, of four limbs, or paraplegia, is, according to Müller, the most frequent. But having regard to what I have described, I would suggest that it is probably more common for the lesion to clear off to a large extent in infants than in adults. I feel sure that it is very uncommon for a single limb to be alone struck by the disease. Synergic muscles are frequently attacked, and frequently recover together.

Müller, in a case in which he had the opportunity of testing the muscles from the first day for one and a-half years, found that the faradaic muscle excitability still persists when the nerves have lost theirs. On the fourth day faradaic excitability was lost for the nerves; on the fifth for the muscles. Galvanic excitability of the muscles was slightly lowered at first, but in the course of the third week it increased, and A S Z was  $>$  K S Z, but there was not such marked increase as we see after traumatic lesion of nerves. The exaggeration does not last long. There is a return to the normal, or else complete disappearance of contraction. Muscular wasting is visible after ten or twelve days. Regression commences in those muscles which have shown only quantitative change. It may begin in four, six, or twelve days, but more often is delayed for some weeks. Motility returns last in muscles which have shown the gravest signs of reaction of degeneration. Regression is very rarely complete.

According to Duchenne the attitude of a limb depends almost exclusively upon the tonicity of the muscles which move it. The muscles are like so many springs, which, during muscular repose, maintain the limb in its normal attitude. If one of these springs become weak the equilibrium of these tonic muscular forces is broken, and the limb is dragged, in a continued manner, into vicious directions. Hence in this disease there is greater risk of serious deformity than in any other form of paralysis. In most paralytic conditions the muscles of a limb are rendered to all intents equally powerless—the interruption of innervation affects them alike—and as a result, though the limb may be useful, its symmetry may remain undisturbed. But in this disease, as I have had the opportunity of showing you in many cases, side by side with a muscle which is absolutely paralysed and wasted, you may find one which acts to voluntary and electrical stimuli. The unopposed tonicity of this muscle will necessarily cause the limb to assume a distorted appearance.

In other cases all the muscles may be wasted, and the joints so loose that the limb hangs like a flail.

Between the disease as it occurs in children and in adults, the main points of difference appear to be as follows: In the former convulsions are not uncommon at the onset. In the latter these are not seen, but there is usually complaint of pain in the head. It is evident that the deformity will be greater when the patient is attacked during the period of growth than when this has been completed. Hence the results of the disease are not nearly so disfiguring when it takes place in adult life as when children are attacked. In either case the position assumed by the limb, besides being influenced, as I have described, by the want of balance in the muscles, may be also much affected by the presence of more or less sclerosis of the lateral columns of the cord, which is

apt to occur in connection with the affection of the anterior grey matter.

In advanced cases of acute atrophic paralysis in children, the affected limb is often much smaller than its fellow, and this not only in circumference but in length. Duchenne has seen a limb in the course of a few years measure 6—8 centimetres less than its fellow. This arrest of development of the osseous system is not necessarily in proportion to the extent of the affection of muscles.

A limb may have lost the greater part of its muscles and yet be only 2—3 centimetres shorter than that of the opposite side; whilst in another limb shortened by 5—6 centimetres, the muscular lesion may be localised in one or two muscles. The ligaments become so lax that the head of a bone no longer touches the socket in which it should rest. I would mention here that, remarkable as is the effect upon the size of the bones, it is evident that we have not to do here with a rapidly destructive process as in the affection of bones and joints in tabes. The bone ceases, or rather nearly ceases, to grow, or perhaps it would be still more correct to say that its growth is enormously retarded. This arrest is quite in accordance with what might be expected from the interference to the blood supply of the limb. Its temperature is much lower than normal, it looks blue, the skin is ill-nourished.

Yet we never, so far as I have seen, get in any of these cases either spontaneous fractures of a bone, or that active and rapid destruction of a joint with absorption of the articular extremities which is so remarkable a feature of tabes dorsalis. Considering the extensive character of the destruction which overtakes the anterior cornu in many of these cases it seems to me impossible to suppose that if the arthropathy of tabes were really traceable to lesion of the anterior cornu we should not get examples of a similar arthropathy in the course of infantile paralysis.

#### TREATMENT.

Were I to have the management of a case of this disease from the first hour I should be disposed to adopt some such line of treatment as the following:—

The patient should be kept absolutely at rest in bed, a light diet administered, counter-irritation in some form applied to the neighbourhood of the spinal column, and the bowels emptied by a mercurial, followed by a saline purgative. At the same time it would be well to give the liquid extract of ergot in full doses, at intervals of an hour or two at first, and gradually less frequently—the administration of this drug not being continued beyond a week. At the end of eight or ten days the faradaic reaction of the muscles should be carefully tested and recorded, but induced currents should only be applied for the purpose of testing. For treatment I should apply a continuous current from 5—10 cells from the nape of the neck to the bottom of the spine for five minutes daily, taking care to increase the strength of the current from zero upwards gradually, and at the end of the application to lower it to zero before removing the rheophores so as to avoid shock. The constant current might be applied in this way for three weeks at a time, then omitted for a week and re-applied as before for three or four weeks.

It seems to me that there is a positive objection to the use of faradism to the muscles, especially in an early stage of the disease. Let us be as careful as we may in thoroughly wetting the skin and the rheophores, it is impossible to apply induced currents without, to a certain extent, stimulating the cutaneous nerves. Now, impulses started thus in them are conveyed by the posterior roots to the grey matter of the cord, and thence doubtless strike the large ganglionic cells in the anterior horn. In the state of inflammation in which we may suppose them to be, it is evidently desirable to avoid this source of irritation.

Indeed, as regards the use of electrical application to the muscles at any period, it seems to me of doubtful advantage. The difficulty we have to contend with in

this disease is, I have said, that motor impulses fail to reach the muscles, and this difficulty is not met by endeavours, more or less successful, to cause contraction in the muscles by electrical stimuli. The best example of recovery which I have shown you occurred in a child who had no electrical treatment at any period. It is notorious indeed that the more or less rapid return to their proper function of many muscles which we so often see occur in the disease, may take place in the complete absence of any electrical applications.

I cannot help thinking that the extremely energetic electrical treatment which it is occasionally the fashion to employ in cases of this disease, has sometimes a mischievous effect. A mild constant current, on the other hand, may not have any powerful effect, but I do not think it does harm. Its use is constantly attended with a sense of increased warmth in the affected limbs. With the same object the limb should be kept well covered, and may be rubbed a little. When signs of contraction and deformity begin to appear it is well to have the limb provided with an apparatus which shall compensate as neatly and simply as possible for the lost muscular power, and endeavour thus to prevent deformity as far as possible.

I would not encourage voluntary movements of a limb in which the muscles are unequally strong, and for this reason: Duchenne has shown that in all muscular movements there are two forces at work—one which produces the movement, the other which moderates it. If the directing muscle overacts, it is because the moderating muscle (its antagonist) becomes muscularly insufficient to repress its action. When we flex the hand we do it slowly or quickly, by letting the extensors act very much or very little. Both flexors and extensors act in flexing or in extending the hand. In lead palsy, when the extensors are paralysed, the grip is weak.

If in polio-myelitis, with paralysis, say, of the peroneus longus, you encourage the patient to try and press down the inner border of his foot, you excite him really (in the absence of action of the peroneus longus) to throw into contraction its antagonist, the tibialis anticus, which is, we will say, sound, and you thereby only intensify the deformity.

### CERTAIN CONSIDERATIONS REGARDING CHOLERA AND FEVER. (a)

By SURGEON-GENERAL C. A. GORDON, M.D., C.B.,  
Honorary Physician to the Queen.

(Continued from page 155.)

As a contrast I quote thus with regard to cases said to have been of enteric fever at Ascension. (b) The water supply, rain water, spring water, to which all contamination is prevented, and condensed water; all three waters kept stored in stone and iron tanks, and cannot by any possibility be exposed to sewage contamination; and yet nine cases of "enteric" fever are said to have occurred on that island; the characteristic symptoms of that disease present in all its varying degrees. No material impurity in the water or tanks; no fault with the hygienic state of the garrison, or of the farm establishment at Green Mountain.

**Food and Milk.**—In certain Eastern nations, particular articles of food are, by means of religious and other enactments, declared unwholesome; in other countries those articles are in common use without evil result. In India the use of milk is general, many sects of natives consuming it in great quantities. These classes are careful, however, that the milk so used by them is in the first instance boiled, coagulated, and otherwise prepared. Experience on their part, and on that of Europeans in that country, indicates that in an unprepared state, but particularly in places where cholera is endemic, or where it is

epidemic, there is considerable danger attending the free use of this product. But there is no apparent reason to assume that the actual source of such danger is anything exterior to the changes which spontaneously take place in the fluid as a result of general conditions prevailing in that particular place. In China milk is looked upon as an *excretion*, and abhorred as unclean. No doubt there are sanitary reasons for its being so. In India instances have occurred in which there could be no reasonable doubt that cholera has been induced by the use of milk containing water contaminated by cholera dejections. But, on the other hand, infants fed at the breast by nurses ill with cholera, if in some instances they have been themselves attacked, they have escaped in others. As a general result milk contaminated by cholera matters is most dangerous to individuals partaking of it.

With regard to fever, only such as is attended by ulceration of the small intestines has been attributed to contaminated articles of food, including milk. How stand the facts in reference to this point? In no single instance of the somewhat numerous cases investigated by me in India was a connection traced between the occurrence of fever said to be enteric or typhoid, and the use of contaminated or deteriorated meat. Indeed, no such meat was made use of either by soldiers or their families. As to instances in which elsewhere the occurrence of typhoid fever has been attributed to this cause, the disease thus induced has subsequently been referred to trichinosis, and then to sausage poisoning. On this point I refer to remarks already made in this paper under the head of *Specific Origin Theory*.

I am aware that cases, said to have been of enteric fever, have, by competent writers (a) been attributed to eating tainted *tinned* meat, the circumstance assigned theoretically to the development of an assumed poison, putrogen. Also that there are those who believe that eating the flesh of an animal affected with typhoid fever *can* bring on the disease in the person who eats it. Compare these remarks with those already made, and then with the following:—

At Shanghai in 1872 rinderpest prevailed extensively among the cattle. Beef of animals thus affected was extensively eaten by the sick inhabitants; no evil result followed. But as expressed by the reporter "it is absurd to recommend people not to be alarmed, when the meat which supplies their tables may have been cut from animals dead of a disease which from post-mortem appearances might be described as a combination of diphtheria, typhoid fever, and dysentery." (b) In India the Kotahs, a Dravidian tribe inhabiting the Neilgherie hills, habitually eat carrion, and in Bengal certain wandering mendicants devour dead matters of the most horrible kind, (c) in both cases without any such result as might be looked for to accrue. I purposely refrain from prosecuting this part of my subject as it refers to England. It is on record (d) that in Paris people have inoculated themselves from animals suffering from cattle plague, have eaten the flesh of those affected with that form of disease, and even of those affected with carbuncle without evil result. It is, moreover, stated on authority that the cooked flesh of those suffering from typhus is not unfit for food. According to a paper submitted to the Paris Academy of Science, although milk from cows suffering from typhus is unwholesome, in other respects "neither it nor meat are capable of transmitting typhus to man or any animal except a *ruminant*." (e) As to the generally pernicious and most objectionable qualities of contaminated meat and milk there is no question. But we are dealing with specific diseases, and them only. (f)

10. *Youth and Recent Arrival.*—As a principle, all ages are equally liable to attack by cholera during epidemics of that disease. As a second principle, the recently-arrived European, of whatever nationality, is more liable to be attacked than those of longer residence. Exceptions to this occur, however, notably in the outbreak of cholera among the cavalry at Secunderabad in 1871. On that occasion the men first attacked were those of longest residence in India, and there are other instances of the same kind. But these exceptions are not sufficient to affect the general rule as expressed.

With regard to fever in India and the tropics generally circumstances are somewhat different. In all, sickness, especially by the several forms of fever, but particularly such as affect intestinal causes, attacks the young and recent arrival to an extent proportionally greater than it does the man of more mature years and longer residence. Inasmuch as in temperate climates seasonal conditions which prevail in autumn induce bowel complaints in various forms, so in the tropics corresponding seasonal conditions produce similar results, whether as independent affections or as complications of others. Youth and adolescence are the periods during which deposits in, and other affections of glands and gland-like tissues are of most frequent occurrence. Hence, doubtless, the occurrence of infiltration, and in some cases of ulceration in the glands of Peyer in other diseases than fever, and in some instances where during life there was no apparent illness whatever. This circumstance has in India presented itself in cases where death by heat apoplexy occurred within a couple of days after attack. Such a state of glands appears to me, like scrofula, to be properly indicated as a *condition*. But where the condition exists, there constitutional disease however induced, will naturally affect tissues thus impaired, nor is the introduction of a specific poison required to bring about that result. Young soldiers are more impressionable to all forms of endemic disease than old; they are also more indiscreet and inexperienced as regards exposure to well-known causes of illness.

11. *Races.*—In some epidemics of cholera the natives of India suffer more severely by that disease than do foreign residents; in others they suffer less. Aborigines of the hilly districts of Nagpore are said to be exempt from cholera so long as they remain in their own native localities, but to be peculiarly prone to that disease when they enter the plains. A similar circumstance has been observed in reference to Ghoorkas from Nepal; and it is further on record that during the epidemic of 1869 in Persia scarcely a negro escaped. In that of 1877-8 in Southern India the disease affected Europeans to a small extent compared to what it did the natives. And yet, with a very few exceptions, cholera has in turn affected all nations and nationalities. This remark applies also to small-pox. (a)

On the coast of Guinea the native African is to a great degree exempt from fever, by which the European visitor is nearly certain, sooner or later, to be the subject, and very often the victim. The native races are altogether exempt from those outbreaks of fatal epidemics which from time to time have made havoc in ships' crews in the

east rabbit flesh, and that rabbits may have become infected by contagion from the discharges of a typhoid patient. Beaugrand gives the case of typhoid fever caused by eating the flesh of a wild kid caught in a snare. He has ascribed diarrhoea and other illnesses to eating rabbits.

(a) In China a large proportion of European mothers are unable to suckle children. Small-pox and syphilis, when attacking races for the first time are characterised by a virulence and deadliness seldom met with in their subsequent history. An extension of the same principle will help to explain the decay of epidemics, or the complete extinction of some diseases. "Chinese Customs Reports," July-September, 1872. P. 31. "The acquisition of a high degree of civilisation, humanity, and science, tends to the fostering and propagation of forms less able to resist disease on account of its endeavouring to preserve, and its success in fostering the weak and susceptible. This is a drawback to civilisation." Op. cit. P. 32. This picture can scarcely be said to be complimentary to modern Hygiene.

estuaries of those great rivers which occur along the West Coast from the Gambia to the Gaboon. In India it is stated that Non-Aryan races in Assam suffer to a comparatively greater extent from "malarial" diseases than do Aryans in the same provinces. On the other hand, a race of people, namely, the Tharoos, Aryans by race, withstand the pestilential climate of the Oude *terai*, which is deadly to all others. (a) In China, the native of the country and the European appear to suffer equally from malarial fever, and from that form designated typho-malarial. (b)

Natives of India and Europeans of various nationalities suffer from altogether different diseases, and variously from the same diseases. This rule holds good to such an extent as affecting the very existence of the British as permanent settlers in, and colonists of, that country that so far as I am aware the assertion of a very eminent medical officer has never yet been controverted, namely, that a third generation is wanting of pure Europeans resident continuously in India, and without admixture of new or imported "blood." (c) Thus, by analogy we are led to what is demonstrated by actualities, namely, that the phenomena of disease differ according to race. This is so to a marked degree in the cause of fever. But of this again, under the head of climate.

12. *Individual Conditions.*—Although delicate physique and ill-health predispose to cholera, and persons sick in hospital manifest a great liability to attack and death by that disease when epidemic, yet exceptions are so frequent that a rule on this subject is far from absolute.

With regard to tropical fevers circumstances are more defined. Thus, according to a recognised authority (d) on this subject "the severe or ardent fever, called also climatic, or seasoning fever, occurs among the recently arrived,—and more especially among the young, the intemperate, the robust and plethoric, and among those exposed to the sun in very high temperatures." "According to the views formerly held in India, fever occurring in such subjects, sthenic in its earlier stages, in its later became complicated with visceral derangement, intestinal and otherwise, attended by a low, typhoid, or adynamic state, in persons of weakly frame, asthenic from the first. Of fever in Bermuda a similar observation occurs, namely, that "pathological changes depend upon contingent circumstances, personal and otherwise, that enteric fever (that is, fever with intestinal complication) invariably occurred in persons of feeble vascular development; while it was observed that the simple continued fevers without bowel lesion, were generally in persons of more robust frame." On the other hand physical conditions, manner of life and habits, whether natural or acquired, may be modified as to predispose to adynamic forms of disease, and to determination to particular viscera.

13. *Climatic and Seasonal Influences.*—Under the operation of the sum of conditions briefly expressed as climatic differences specific and generic, occur in all branches of the great organic kingdom met with in the several zones; often also, in different parts of the same zone. That a few, extremely few exceptions which occur but tend to prove this rule is doubtless true; but the rule is as stated. And so, also, with disease. As with growth and develop-

(a) Tharoos, believed to have been originally from Chittore, whence they escaped on the capture of that place by Akbar about A.D. 1560. They claim to have been originally Rajpoots; that their ancestors lost their caste by drinking intoxicating liquors and rearing fowls. The present descendants are much given to the vice of drunkenness. They keep their houses scrupulously clean. They drink water from wells only.—Sir John Elliott's "Races of India." Vol. 1. Pp. 317-18.

(b) From the "Customs Reports," July, September, 1872, p. 59.

(c) This question of the relation of race and disease presents considerable difficulties. While in China the native Chinese suffer from malarial fevers to quite an equal extent as Europeans ("Customs Reports," July-September, 1872, p. 35), the natives of India in many instances similarly suffer more than Europeans. On the other hand there is reason to believe that the Jews in England are more healthy and long-lived than the English people are.

(d) Copland.

ment, so with decay, and often the manner in which this takes place all of these are affected by conditions, geographical and climatorial. Hence arises the general question of geographical distribution of disease. (a)

As in temperate climates, the process of growth, development, and subsequent disintegration are, for the most part, in progress slow, so in tropical are they rapid. If, in some instances, animals and plants undergo, more or less completely, a process of acclimatisation when introduced from one climate to one nearly similar, the great majority refuse to do so; while of those introduced from a climate of particular characters to one altogether different, many perish, and those that continue become modified in various ways, lose the power of reproduction, or their descendants rapidly degenerate. And so with regard to manifestations of disease, the nature of attack, the organs most liable to suffer differ under one set of climatorial conditions from what they are in another.

On this section of my subject, I summarise conclusions expressed by a competent and recognised authority. (b) "The primary effect of great changes of climate are on the circulation; the blood drawn surface-ward by heat, driven in by cold. The secondary effect is increased external vascularity during heat, internal during cold. In the tropics the vascularity of adult lungs is reduced, so also are their spirometric measurement, their functions, the nephritic vascularity and secretion; those of the skin are increased, the circulation becomes more languid, the pulse less frequent and less forcible; the organs and functions of animal, like those of vegetable life, are affected by great changes of climate, heat impairing the weight, strength, and health at all ages, and retarding growth in youth." The balance of conditions and functions here indicated being more or less completely and suddenly deranged, disease becomes a natural result. It so occurs; its type and incidence as regards organs and tissues influenced by conditions already stated.

Those who, depressed, worn out by endemic disease, or by simple exhaustion incidental to a tropical climate, say of Bengal, as an example, speedily realise the benefits of a trip to sea, or to the bracing atmosphere of the Himalayas; so do they alas! and very often conversely, when scarcely half recovered, duty forces their return to localities in which their health gave way. To such, and they are many, the expression climate indicates a very stern reality. (c)

A very eminent authority (d) writes on the same subject thus: "Every year we have some atmospheric element, which neither thermometer nor barometer, neither rain nor wind-gauge, nor measure of moisture, nor test of ozone, can reveal to us, but only our records of sickness and death. One year it is such as favours small-pox, the next, perhaps, it will promote scarlet fever, or measles, or whooping-

(a) In what may be called the Western tropics, the modifications of fever are thus noticed by a very distinguished member of this society. "Cases commence as remittent, and continue as such from the 6th to the 10th day, on the same afternoon the fever recurred, rapidly took on the character of yellow fever, and proved fatal on the 4th or 5th day of that form. In other cases which commenced as intermittent, diarrhoea ensued, after three or more tertian periods the fever became continued, assumed the character of typhoid, ultimately presented the affection of the kidneys, and urine seen in yellow fever, then terminated in death. The intermixture of morbid appearances peculiar to yellow and typhoid fevers were detected in variable proportions." Inspector General Lawson, *Medico-Chirurg. Review*, July, 1889, p. 225, printed in Chinese Customs Reports, 6th part, July-September, 1872, page 59.

(b) Dr. Rattray. Paper before Royal Society.

(c) "It is a common observation with men, when discussing the unhealthiness of these climates (China), that their evil reputation is not deserved, that they are as healthy as our native lands, and that we should find them so, did we only assimilate our diet and habits to those of the natives." "There is a sophistry about this which deceives some, and others like it, because they belong to a morbid class, who have a natural tendency to do anything entailing a self-denial, who think that whatever is pleasant, must be bad, and whatever is unpleasant, and involving self-denial, must be good."—"Chinese Customs Reports," July-September, 1873, p. 82.

(d) Dr. Guy. "Public Health," p. 31.

cough, or it will, so to speak, select from several forms of fever that one which shall fill the beds of our fever hospitals. The condition of air, which disease itself is the only test and measure, was once called pestilence, but is now known as its *epidemic constitution*—"la disposition atmosphérique génératrice."

(To be continued.)

## Clinical Records.

### ST. PETER'S HOSPITAL.

*Stone in the Bladder.—Lithotriety.—Recovery from the operation and departure from the Hospital.—Death, subsequently, from Malignant Disease of the Bladder.*

Under the care of MR. TEEVAN.

JOHN B., a coach plater, æt. 69, was admitted in the hospital on August 1st, 1879.

*History.*—From notes taken by Mr. S. P. Phillips, the house-surgeon, it appeared that the patient had always enjoyed good health. For the past two years he had suffered from pain in the back, especially at the left side, but there was no evidence of the descent of a calculus. For the last six weeks he had been obliged to pass water very frequently, attended, occasionally, with great pain, which was felt in the supra-pubic region, and was relieved by micturition. At times he had passed blood very freely. For the past fortnight the symptoms had been less marked. The patient was born in Southwark, his father in Wiltshire, but he was ignorant of his mother's birth-place. On June 29th he was sounded by Mr. Teevan, in the out-patients' room, who found a stone. The patient was a large, well-made man; body well nourished; face very pale.

July 2nd.—Mr. Teevan introduced a lithotrite and crushed a small phosphatic stone. He could not manipulate the instrument on the left side of the bladder on account of what was, apparently, a tumour occupying that situation. Blood flowed freely during the operation, but there was no pain, rigor, or rise in temperature afterwards. Mr. Teevan stated, at the time of the operation, that he considered the tumour to be malignant on account of the attacks of hæmorrhage, the dark colour of the blood, the supra-pubic pain, and the free bleeding caused by the manipulations of the lithotrite.

9th.—The patient having been put under the influence of ether, by Mr. Knott, Mr. Teevan crushed a small, hard stone, about the size of a hazel nut. During the evening the patient passed many clots of blood, attended by much strangury. No pain except on these occasions. T. 100.

10th.—Slept badly, on account of frequent micturition and strangury. Tongue dry; T. 102; pulse 100. Ordered citrate of potash, and liq. ammon. acet.

11th.—Is constantly passing urine tinged with blood. Pain in hypogastric region. Has passed a few fragments. T. 98.4. Ordered gallic acid.

16th.—Lithotriety: bled profusely afterwards and suffered much pain in bladder. Several small fragments passed. One quarter of a grain of morphia, injected hypodermically.

17th.—Pains in head, T. 102. Still passing blood. Iron ordered.

19th.—Pain in bladder, very severe when micturating. Slight rigor at 5 p.m. T. 105.

20th.—Better; urine clear. T. 99.

28th.—Sounded, some stone felt.

29th.—Lithotriety.

30th.—A large quantity of sand and grit came away, but no blood.

Aug. 1st.—Feels well; left hospital; able to walk well, and feeling strong. A month afterwards Mr. Teevan received a letter from Dr. Andrews, of Hammersmith, saying that about a fortnight after the patient left the hospital he was called in to see him on account of sudden and violent hæmorrhage from the bladder, which carried him off in a few days. The bleeding was apparently caused by malignant disease.

*Stone in the Bladder.—Lithotomy.—Severe Secondary Hæmorrhage.—Recovery.*

Under the care of Mr. TEEVAN.

William B., æt. 7, was admitted into the hospital on Nov

5, 1880, suffering from a stone in the bladder which Mr. Teevan had detected.

*History.*—From notes taken by the house-surgeon, Mr. Whitehouse, it appeared that the patient had a severe attack of rheumatic fever two years ago, which left his heart permanently injured. Soon afterwards he began to complain of pain when making water, which he relieved by pressing the end of his penis. He was unable to run about on account of the suffering it caused him. He occasionally passed blood after paroxysms of pain. The boy was a native of London. His father was born in Berkshire, and his mother in Wiltshire.

*Condition on Admission.*—The child was pale and thin, with dilated pupils. He had to make water every half-hour day and night, and cried loudly when it passed. The urine was acid, but did not contain albumen or phosphates. Its sp. g. was 1020. Dr. Thorowgood examined the boy's heart, and determined the existence of a mitral regurgitant murmur, and an aortic systolic one. On Nov. 24 the boy was put under the influence of chloroform by Mr. Knott, as Dr. Thorowgood, Mr. Knott, and Mr. Teevan had all independently come to the conclusion that that would be the best anæsthetic in the particular form of heart disease from which the boy suffered. Mr. Teevan then passed a rectangular staff, and having committed it to Mr. Heycock's charge, he extracted by the lateral operation a phosphatic stone measuring  $\frac{1}{4}$ -inch by  $\frac{3}{8}$ -inch. As there was free bleeding, a carbolised sponge was inserted in the wound.

Nov. 25th, 8 a.m.—There was some bleeding in the night, which Mr. Whitehouse arrested by pressure, temp. 99, pulse 120. Patient suffers much pain at tip of the penis. Urine passes freely through wound.

26th, 9 a.m.—Has had a good night. Looks well. Temp. 99, pulse 127.

27th, 9 a.m.—Does not look well. Ordered a dose of castor oil as his bowels had not been opened since the operation. Temp. 102, pulse 120.

28th, 9 a.m.—Has had a good night. Bowels open freely. Temp. 99, pulse 120.

29th, at 5 a.m., whilst on the bed pan, the patient passed a large clot of blood, and several smaller ones shortly came away. The wound was plugged with a carbolised sponge. Looks very pale and weak. Is restless and irritable. Temp. 101, pulse 126.

Dec. 4th.—Since the last report the patient had improved in health. Whilst on the bed pan at 3 a.m. about half-a-pint of clotted blood was expelled. As no spouting vessel could be seen Mr. Whitehouse plugged the wound with lint and applied an ice bag to the hypogastric region. The motions were of a dark green colour, slimy and offensive. At 4 a.m. the boy had another attack of hæmorrhage immediately after the bowels were open. He looked very blanched and his pulse was very small and rapid. Mr. Teevan was sent for and arrived at 4.45 a.m. From that time up to 8 a.m. the boy passed a motion about every hour, followed by the expulsion of a large clot. He was very restless and vomited once. Pulse 150.

From the day of the operation the boy had lived entirely on milk. Mr. Teevan came to the conclusion that the hæmorrhage was caused by the diarrhœa, for there was no bleeding in the intervals between the motions, and that the diarrhœa was produced by the milk. He, therefore, removed all lint and ice-bags, and left the wound quite open. Five drops of tincture of opium were given, and repeated once only half-an-hour afterwards. The patient's milk was changed, and he was fed exclusively on milk, procured from a different source—the Aylesbury farm dairy. At 9 a.m., four large dark-coloured clots of blood were expelled, attended by a great rush of urine, and followed by much relief, for the child had complained greatly of tenesmus, and pain at the end of the penis. 7 p.m.—The bowels have not been open since the opium was given, and there has been no more bleeding. Ordered four more drops of opium.

5th.—No more bleeding. Takes large quantities of milk. Urine passes freely through wound.

9th.—Looks much better; no more bleeding. Bowels opened by an enema for the first time since the 4th.

21st.—Since last report, the boy's progress has been uninterrupted. The wound is quite healed, all urine having come through the penis for some days past.

30th.—Discharged cured.

Feb. 27th.—The boy was brought to the hospital by his mother. Health much improved. Has a slight amount of incontinence if he runs about. None at night.

## Transactions of Societies.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 25.

DR. ALTHAUS (in the absence of the President) in the Chair.

DR. HILTON FAGGE read notes of

A CASE OF PARALYSIS DUE TO PARTIAL DISEASE OF THE NUCLEI OF THE MOTOR ROOTS OF THE 5TH NERVES.

W. B., æt. 41, was admitted into Guy's Hospital on Oct. 18, 1880, on account of inability to close the jaws. He said that three months ago he began to experience difficulty in holding anything tightly between his teeth, and that afterwards he could not bite his food well. The loss of power gradually increased until, 3 months ago, he became quite unable to bring his teeth together. He also had difficulty in swallowing, and liquids returned through the nose. The drop of the jaw was still slowly becoming more marked. He was a strong, healthy-looking man, but his expression was vacant, and his features had lost much of their play. This, however, was not due to any defect of the 7th nerves (for he could whistle a tune perfectly well) but to separation of the jaws. When he tried to bring the upper and the lower teeth together, he could not do it; the temporal muscles could in fact be scarcely felt to contract, and the masseters acted very slightly. The excitability of these muscles to the continuous current was much impaired, and they were obviously wasted. Yet the lateral movements of the lower jaws, performed by the external pterygoid muscles, were normal. On inspection of the fauces the soft palate was seen to move symmetrically during respiration; but the left side of the palatine arch was dropped, and narrower than the right side. It appeared clear, therefore, that the case, which (so far as Dr. Fagge knew) was unique, was one of a partial lesion of the motor nuclei of the 5th nerves, comparable with bulbar paralysis and with Mr. Hutchinson's *ophthalmoplegia externa*. And, as in the last-named disease, the cause was possibly syphilis, for the man had 20 years previously had gonorrhœa and a bubo, and his wife, to whom he had been married 19 years, was never pregnant. Another interesting symptom was the presence of sugar, to the amount of 54.7 grains per ounce, in the urine, which was of sp. gr. 1049. He also complained of slight occasional diplopia; and the muscles of the arms and the extensor muscles of the forearms were found to have a diminished capability of resisting, both to continuous and to faradaic currents. He was ordered to take 1-12 grains of bichloride of mercury, and 10 grains of iodide of potassium, three times a day. Under this treatment he rapidly improved, and he refused to stay in the hospital after the 6th of November.

DR. ALTHAUS: Such cases are very rare, in which, that is, only one portion of the nerves is affected. He recalled a case in which all the fifth pair had undergone paralysis, no localisation in the motor roots being exhibited. There was considerable tinnitus aurium, and the soft palate underwent displacement. Had tinnitus aurium occurred in Dr. Fagge's patient, and had the condition of the eyes been investigated? The physiology of the eye might be much advanced by careful observation of such cases as that recorded.

DR. DOWSE suggested that the disease was not limited to the fifth, but implicated also the glosso-pharyngeal and vagus nerves, the latter, he thought, was proved to be influenced, by the vomiting. The paralysis was extending downwards, as shown by the loss of power in the upper limb. He thought the case might either be allied to pachymeningitis, or might be one of extreme bulbar paralysis.

DR. POORE, from examination of the patient, concluded there was a deviation of the tongue on the right side. He inquired if the masseter responded to galvanism.

MR. GODLEE remarked that it was interesting to note the ability with which the buccinator muscle acted.

DR. FAGGE said he had been unable to make out any increased susceptibility of the affected parts to the current. There had been no tinnitus; no ophthalmoscopic examination was made. The vomiting was easily explained as due to the state of the palate, and not to affection of the vagus. The hypothesis of bulbar paralysis was more tenable than that of pachymeningitis.

DR. ALTHAUS suggested that the patient should be kept under observation; and

Dr. FAGGE promised to bear the advisability of this in mind.

Mr. T. W. TRALE, of Scarborough, described a case of QUIESCENT SCIRRHUS,

which is still under his care. A lady, *æt.* 53, a widow, noticed eleven years ago a small, hard, painful lump in the left breast. The surgeon whom she consulted advised its removal, and Mr. Teale, who saw her soon after, considered it malignant, and gave the same advice. All idea of operation was declined. The tumour gradually increased, becoming adherent to the ribs; the nipple was retracted, and then obliterated. Pain, which was often excruciating, was relieved by morphia, taken up to four grains daily, and sleep obtained by chloral in increasing doses up to sixty grains. She became emaciated, feeble, bedridden, and apparently at death's door, living for two years on milk only. Eventually, the chloral having been discontinued, owing to the distressing nervous symptoms to which it gave rise, a gradual change in the symptoms took place. The bodily health began slowly to improve, whilst the tumour began to shrivel, the discharge ceased, and the pain gradually diminished. Mr. Teale reported that during the last five years the patient has remained well and fairly strong, able to walk some miles daily. She has gradually resumed ordinary diet and modes of living, and takes less than a quarter of a grain of morphia daily, whilst the present condition of the shrivelled breast tumour was shown by a photograph recently taken, which Mr. Teale exhibited to the members.

Dr. ALTHAUS.—Instances of quiescent cancer do occur, and have been termed "retrogressive." Diagnosis is always important in such cases, and it would be well if direct examination of a portion of the tumour could be made in every instance of doubt.

Dr. T. WILLIAMS considered the experience obtained with chloral gave the case additional interest. He was inclined to question the accuracy of ascribing the symptoms which left the patient, when chloral was discontinued, as being entirely induced by that drug. Might not the morphia be partly to blame? Dr. Williams cited examples of tolerance of chloral exhibited by patients, including one who, by his direction, took 10-grain doses every four hours, for several days, on account of *æsthesia*. The spasms were reduced, and a purpuric rash was the only ill-effect produced. He failed to see why Mr. Teale's patient was differently affected.

Mr. BARKER having commented on the interesting questions raised by consideration of the case,

Dr. FAGGE remarked on the difficulty of distinguishing characteristic cells in chronic carcinomatous tumours. Correct diagnosis of hard cancer demands the utmost carefulness, and he had seen cases in which the malignant nature of the growth could be decided only after the most elaborate examinations. It often occurred that what is really cancerous tissue is often made out as a fibrous structure, and hence, where this is found as a result of the affection of a part in which cancer is commonly found, it ought to be at least suspected that its real description may be that proper to malignant deposits.

Mr. GODLEE asked if the axillary glands had undergone any recent changes?

Mr. HAWARD agreed with Dr. Fagge that the fibrous condition of the growth by no means removed it from the possibility of carcinoma. Proof that the conditions may be allied is to be found not unfrequently in the diseased rectum. The inquiry, however, naturally arises in this connection, what leads to the arrest of active, destructive, tissue changes, consequent on the disease? This must have an important influence in determining whether to feed a patient, suffering from cancer, freely or sparingly. He thought himself, that the growth of the tumour would be stimulated by over-nutrition of the patient. He knew a lady affected with scirrhous for years; she indulged in morphia, but took little food. The cancer ulcerated, left an open wound, which continued to discharge thin offensive matter for two to three years. Five years from first attack, a growth occurred in the other, the right breast, and grew slowly for a year. In addition to morphia, which had been used all along, the patient now drank much brandy. The right cancer grew rapidly on this food, and nodules occurred in the skin. The patient died, and there is good reason for assuming the change of diet, the copious indulgence in brandy, hastened the end. Mr. Haward strongly inclined to recommend starvation to patients with malignant growths.

Mr. TRALE said his patient continued to use morphia throughout, but as all the ill-symptoms described left her when the chloral was given up, he naturally ascribed their presence to the effect produced by the chloral. He only recorded the fact, however, and in no way desired to urge it as a cause. The axillary glands remained in much the same condition, no progressive changes occurring in them. Mr. T. Pridgin Teale, of Leeds, had seen the case also, and concurred in the diagnosis of it; he did not doubt the malignant nature of the growth.

Dr. RADCLIFFE CROCKER described four cases of

ERYTHEMA, OR HERPES IRIS,

one of which had been shown to the Society at a previous meeting, and another was brought to the present meeting to show the scars which sometimes result from this affection. A wax model of a typical case was also exhibited.

W. G., *æt.* 23, a butcher, had suffered from three attacks, and though there was no evidence to show what led to the first attack, which occurred during a voyage to the Cape, subsequently errors in diet aggravated or determined an outbreak. His general health was good, except a tendency to constipation. The eruption appeared most abundantly upon the hands and face, especially the fingers and toes, but other parts of the limbs, and even the lower parts of the trunk were sometimes affected, the lesions were symmetrical, though often one patch was nearly well before the corresponding one on the other limb appeared. Each began as a flat red papule about 1-16th of an inch in diameter, with a red areola about half an inch across; sometimes a pustule appeared on the papule, which ruptured, and a brownish pink zone appeared round it, and outside that a white one, and the patch increases by the formation of fresh rings, varying from white to pink or bluish red tints, and reaching to about the size of a florin; the rings then broke up, and the patch gradually faded, leaving a purplish red stain, which lasted for some time. The eruption was attended with burning and itching, but the general health was unaffected. Dr. Crocker alluded to the other varieties of this affection. Thus in some no central vesicle or pustule was formed, but only a flat papule, which became depressed in the centre, and concentric rings spread from that; on the other hand there might be a large vesicle or even bulla in the centre, with concentric rings of vesicles, which gave rise to the name herpes iris. The tint of the rings in all varied from white to various pink and bluish shades of red. These variations depended mainly upon the quality of the fluid effused into the tissues. In the child that attended the meeting the eruption began as rings of erythema an inch in diameter; in a few days these disappeared simultaneously with an outbreak of bullæ of large size, round which came a ring of vesicles, and the contents became purulent and dried into scabs, which left the deep disfiguring scars now visible. Speaking generally, the noticeable features of the affection were—its tendency to recur, especially in the spring and autumn, and often in the same month in any one case; 2, to attack children and young adults of either sex; 3, to develop symmetrically, the hands and feet being especially attacked, though in rare instances it was universal; and, finally, to run its course in a few weeks apparently uninfluenced by treatment.

Dr. F. TAYLOR read some cases of

ERYTHEMA AND HERPES IRIS.

The first was a man, *æt.* 40, who had had good health previously. He was seized one day whilst at work with violent sneezing and watering of the eyes, and in the evening found his gums and palate becoming swollen, and could only open his mouth with difficulty. These symptoms subsided in two days, and an eruption appeared. It commenced on the left thigh in the form of blisters, to the number of twelve or more, about the size of a shilling-piece, containing a watery fluid. The following day it appeared on both legs and arms, and he had at the same time, a burning sensation in his feet, and pains in the joints. The eruption then spread to the head, face, and trunk, the abdomen being the only part spared. When seen on the 8th day of its appearance, the eruption consisted of vesicles and bullæ of various sizes, and for the most part arranged in a circular manner, so as to include an area of comparatively healthy skin in a ring of blister. Some such rings were formed of six to eight isolated small vesicles, with clear contents; others of one continuous bulla of crescentic or completely circular form, the contents being then mostly deep

pink or purple. In many places the circles had run together, and formed irregular figures; and some circles and patches measured as much as two inches in diameter. The bullæ were upon a slightly inflamed base. The face was much swollen in the early stage of the eruption. There was no itching, but only a burning sensation, on its first appearance. He began rapidly to improve without special treatment. After becoming full of dark sanguineous fluid, the bullæ burst, the secretion drying into an ulcer; these ulcers were slow in healing, and have left several scars reproducing more or less accurately the crescentic and ring-shape of the original bullæ. They are numerous on the arms, forearms, thighs and legs. The duration of the bullous stage was about three weeks, but the healing of the ulcers took much longer. Two years have now elapsed, and he has had no recurrence.

The second case was in a child aged five months, who had been recently vaccinated. Ten days after the operation the eruption began as pimples on a red surface, completely surrounding the vaccination crests; and subsequently spots appeared on the arms, chest, abdomen, and back. The spots or patches were oval or circular, touching each other by their borders, but not running freely together; of bright pink colour, with deeper red, very narrow, more prominent margin. In the centre of many was a bright red spot, or pimple; and vesicles formed both in the central papule, and at the margin of the patch. The child was seen on three successive days, on the last of which the patches were fading.

The third case was a boy aged nine years, who was generally delicate, and had suffered from cough and weakness for three months. He presented an eruption on the chest, abdomen, neck, back, and lower extremities, consisting of patches of about half-an-inch in diameter, with a central yellow crust; around this an elevated ring, and upon this, again, small vesicles. The vesicles dried up into crusts, and around these formed fresh rings of redness, with new vesicles upon them, and their contents, at first serous, became purulent, and then discharged and formed scabs. When the crusts separated the skin beneath them had a brownish stain. The eruption lasted about six weeks.

Dr. TAYLOR remarked that these might be regarded as three different forms of the disease known as erythema iris, herpes iris, or hydroa, and further defined by Mr. Hutchinson as a vesicular form of erythema multiforme. In the case of the infant it was distinctly an erythema papulatum, or circinatum vesicatum; in the boy the vesicular characters were more marked; in the adult (Case 1) the vesicles appeared before the redness—a feature characteristic of hydroa, according to Bazin. In the sudden outbreak, spontaneous disappearance, symmetrical distribution, and in the co-existing inflammatory disturbance of the joints, it also resembled cases described as hydroa. The large size of the bullæ would have suggested the name pemphigus, as *p. circinatus* or *serpiginosus*.

Dr. STURGE related the history of a boy six years old, who, when admitted to the hospital, had a temperature of 102 deg. Fahr., and remained for six days quiescent. At the end of this time papules appeared on the legs, and extended in a ring-like form from the size of a shilling down. Some were regular bullæ, others were only vesicles. There was coincidentally a crop of herpes on the lips, and pleurisy without effusion occurred, but yielded readily to treatment. In three weeks patient left hospital well of all complaints.

Dr. WILLIAMS remarked that in one case of Dr. Taylor's the disease originated soon after vaccination. Was there any connection between them?

Dr. O'CONNOR had found French cucumber ointment, or oxide of zinc and vaseline act well in curing cases under his care. He had only met with one case of herpes iris on the trunk, it being very rare in this situation. He would like to know what Dr. Taylor's experience had been with arsenic in pemphigus. He once attended a child after vaccination for well-marked pemphigus, and it was peculiar because all the members of the family, viz., father, uncle, and cousin had measles, the child alone excepting, and it developed pemphigus.

Dr. T. COLCOTT FOX said Hebra had made a real advance when he arrayed varying phases of erythema under the single heading *multiforme*. The formation of fluid in bullæ is an uncommon occurrence in erythema; but in true bullous eruptions an aborted stage may be made out, so that there is reason for retaining an intermediate class such as *herpes iris* constitutes. In all true instances of the disease it is characterised by the site of its appearance, on the back of the hands, the knees, &c., &c., always with herpes

faciales. It would be a pity to submerge really distinctive diseases under the common heading *multiforme*.

Dr. CROCKER said symmetry is delayed in some cases, but it always happens that corresponding parts are affected in succession. No treatment influenced the course of the disease. Fever is a common accompaniment of erythema, especially in children.

Dr. TAYLOR said vaccination did not directly influence the attack; it helped to determine the site at which it appeared. He commonly used Fowler's solution of arsenic. The extent of injury to the skin set up in erythema would be dependent on the extent of inflammation.

## Special.

### THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

We are informed by the President (Mr. Erichsen) and the Secretary that the arrangements for holding the International Medical and Sanitary Exhibition, initiated by the Executive Committee of the Parkes Museum of Hygiene, are now complete.

This Exhibition will be held on the occasion of the meeting of the International Medical Congress in London, and will be open from July 16 to August 13. The Exhibition will comprise everything that is of service for the prevention, detection, cure, and alleviation of disease, and will be divided into three sections:—

*Medical Section.*—Surgical instruments and apparatus; appliances of the ward and sick room; drugs, disinfectants, medical dietetic articles and mineral waters; electrical instruments and appliances; microscopes and optical apparatus; apparatus of other kinds used in the investigation of disease; appliances used for the treatment of sick and wounded during war; street ambulances, &c.; appliances used in teaching medicine; books, diagrams, models, &c.

*Sanitary Section.*—Domestic and hospital architecture; planning, construction, decorative materials; ventilation, lighting, and warming; water-closets, sinks, baths, &c.; sewerage and drainage; water supply and filtration; health resorts and sanitarium; books, diagrams, models, &c.

*Miscellaneous Section.*—Application of hygienic principles to food and dietaries, clothing, &c.; school furniture and other articles more or less connected with the general purpose of the Exhibition.

The Exhibition will be held at South Kensington, space having been granted for it by the Royal Commissioners for the Exhibition of 1851. Applications for space from Great Britain and Ireland and the Continent of Europe must be made not later than Thursday, March 31; but applications from India, the Colonies, and America will be received up to April 16.

Certificates of Merit will be awarded to Exhibitors. New inventions exhibited will be protected under a certificate from the Board of Trade. Exhibitors will be charged for space, and it is hoped that the Exhibition, in this and other ways, will be made to pay its expenses. An undertaking of this magnitude, however, is not without risk; and although upwards of £800 has been subscribed as a Guarantee Fund, we hope the Committee will receive such additional contributions as will enable them to thoroughly carry out their work.

## Department of Lunacy.

### "MEDICAL PRESS AND CIRCULAR" SPECIAL COMMISSIONER'S REPORT ON PRIVATE LUNATIC ASYLUMS.—VI.

THE objectors to private asylums,—and this applies to every class of objector, those whose aim is the gratification of personal feelings of whatever kind, as well as those who unrighteously pander to sensation craving,—seem to be oblivious of the fact that on them alone rests any *onus probandi*. They gratuitously invent impossibilities, and then complacently

garnish their assertions with absurdity; finally concluding by impudently dubbing their statement "fact." I have very carefully examined these unblushing compositions; the number of them is a sickening evidence of the most wanton disregard of moral law; but in none is there to be found a shred of reliable testimony. In all, the evidence adduced amounts to, "I believe, &c.," or "I have heard, &c." Nowhere do we come across the avowal, "I have seen, &c.," or "I know from my own experience, &c.;" in none of the nonsense with which a certain type of periodicals is even yet well-padded by those who profess to write for the information of the public on what takes place in private asylums, is there to be found a page of invective that rises for a moment above the character of fanciful hypothesis. It is, however, a grievous reflection that the unwary general reader is without a guard to protect him from the evil influences thus brought to bear on him; the evil is as great to him as to the proprietors, whose fair fame is thus insidiously attacked; for by undermining his confidence in the institutions he rightly ought to regard as sure havens of rest in the dark hour of his mental unsoundness, he is rendered the prey of unreasoning terrors, that may well be expected to hasten the development of incipient symptoms of insanity. Why will not the self-elected traducers of asylums in this country, learn for themselves the injustice of the course they have entered on. The way to do so is simple in the extreme, but the reason why they persist, is, it is to be feared, patent enough. It pays them to be ignorant, and to write in ignorance, however wilful, of the real truth of the matter.

The conduct of servants, and the manner in which their duties are discharged, is one of the most important subjects that arise for consideration in dealing with private institutions. It might, at first sight, almost seem that these officers possessed more uncontrolled influence over patients, than could be the case in public, state-controlled buildings. As usual, with apparent truths, however, the exact contrary to that they seem to teach, is, on examination, found to be the real fact. In the first place, the number of servants in a private house is less, in agreement with the smaller number of patients, compared with the masses under control in public institutions; those few cases where this difference is less marked, a little consideration will show to come within the description to follow. Fewer in number, they are naturally more directly responsible to the superintendent under whom they discharge their duties; and this latter, as has been already shown, being immediately and personally interested in the patients committed to his care, the latter are infinitely better protected from any possible mal-treatment, than in those places where, from the circumlocution attendant on all state offices, a charge, however serious, is filtered through innumerable channels before it arrives before a final tribunal. In another way, too, the private attendant is hedged round by difficulties that effectually prevent him from gratifying any vindictive sentiment he may experience. He might hope to successfully evade discovery of malpractice, when it would be only revealed by complaint of the intimidated patient; and the arrangements of public asylums are sufficiently circuitous to afford no small degree of probability to such chance suppression. In private houses, on the contrary, where a family interest marks the relations of the inmates, it is absolutely impossible that any instance of actual brutality on the part of an attendant, can escape the notice of the proprietor. In every establishment I have had acquaintance with, it has been an invariable rule, for the head thereof to make a daily visit round the whole place, at a time, usually, before the breakfast hour. During a fortnight's residence at one house, I, on two

or three occasions, made my way down from my room, early in the morning, without giving any previous notice of my intention; and, on each occasion, I discovered the proprietor, my host for the time being, on his round of inspection; and thus I learned, what I had been ignorant of before, that this is an invariable custom at all licensed establishments. As night is the time favourable for the perpetration of illegitimate acts, we may safely assume that guilty servants would choose it for their attempts at revenge or cruelty on patients, whenever they were impelled to such performances. The disturbed state of the ward, and the tell-tale excitement of the patient, however, would alike reveal what had taken place under any circumstances of the kind; and any indication pointing to it would forthwith form the subject of minute investigation. It so happened within my experience. A considerable disturbance was created one morning, at Stretton House, and the immediate attention it excited, the noise attracting everyone within hearing distance, conclusively showed the impossibility that anything of the sort would escape notice. This case proved to be a disagreement between two patients who met on the stairs, while proceeding down from the dormitories. A question of precedence arose, and the contention ended in a way to demand the interference of an attendant. The depositions of all parties were carefully received and considered, and had any blame attached to the servant, who was certainly free of any in this instance, he would have met with such summary justice as, we well know, would have rewarded any unjustifiable excess of his licence. It is right, too, to accredit these necessary adjuncts to discipline, with, at least, some share of the common sense spread over humanity in general. An asylum-attendant can hope for remunerative employment only as an asylum-attendant; any violation of the rules under which he accepts service, is severely punished, and is met, moreover, by deprivation of the character, with the aid of which alone he can hope to apply successfully for employment in the same capacity elsewhere. For his own welfare sake, therefore, it behoves him to be careful always of his actions; and speaking from my own knowledge, I can unhesitatingly avow, that with perhaps one exception, the asylum-attendants in private licensed houses I have seen, have admirably answered the requirements to be looked for in a good and able servant, viz., firmness, obedience, gentleness, and command of temper. Much allowance is to be made for them, moreover. Their life is one of considerable temptation to violence, and I venture to think that if the concoctors of sensational accounts of the inhuman brutality of keepers, could but see the almost superhuman patience with which a well-trained attendant tolerates the exasperating conduct of an ill-disposed lunatic, they would blush as much at the injury they have inflicted as their victims would, did they read of the outrages ascribed to them.

In the past, before asylum management was made subject of state regard, and when some private asylum keeper may have regarded his profession as a mere trade, it undoubtedly did occur that servants, left entirely uncontrolled, treated the patients they had charge of with merciless cruelty. But even these instances were few in comparison with the opportunities that occurred to them to be repeated; there are, spite of the black-letter painting of prejudice, only a few men base enough, at any one time, to take advantage of unfortunates unable to defend themselves. At the present day it is safe to assert that not one out of the whole number of private attendants can be described as naturally vicious, and delighting in torture; a character he must possess to be guilty of the crimes laid to his door by sensation-mongers, and dramatists of the intel-

ligence exhibited by the authors of *The World*. Respectability, sobriety, and self-command, are qualities imperatively demanded in applicants for the post of asylum attendant. When these are all exhibited in a marked degree, the servant becomes a most valuable one; and the process of selection, now going on in the asylums of this country, bids fair to produce ere long an absolutely faultless corps of attendants on the insane; to whom, moreover, in no small degree, both the comfort and the progress of patients must be due. Thus much, in defence of an unjustly libelled body of men, has seemed right and called for. It has, besides, a very proper place in this series, and in nothing does it exceed the accurate measure of truth, as might be testified by undoubted testimony.

## The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.

WEDNESDAY, MARCH 2, 1881.

### QUIESCENT SCIRRHUS.

SINCE the discussion on cancer at the Pathological Society, initiated in March, 1874, by the late Mr. De Morgan, the literature of the subject has been extensively added to, and on Friday last Mr. T. W. Teale, of Scarborough, read a communication before the Clinical Society of London, which is likely to rouse afresh the keen interest always associated with consideration of the history, forms, and prognosis of cancer. A brief abstract of Mr. Teale's paper will be found in our report of the Clinical Society's meeting. The subject of it is a lady who, for a number of years, has enjoyed fair average health, while, at the same time, possessing an undoubted cancerous tumour of the left breast. Several deeply interesting questions are suggested in connection with the case, the first and most important being that of diagnosis. On this point the information obtainable is not wholly satisfactory, though the

united opinion of Mr. T. W. Teale, and of his brother, Mr. T. Pridgin Teale, of Leeds, confirmatory as it is of the carcinomatous nature of the growth, leaves no room for supposing that, as far as external examination can be certain, a mistake can have arisen. The circumstances of the case unfortunately prohibited any detailed microscopic investigation into the nature of the tumour, but the history of its progress, and the symptoms attending its presence, go far to lend weight to the assumption of its malignant origin. That it has, notwithstanding, existed for so long a time as eleven years, the last five of which have been passed in comparative comfort by the patient, makes it highly desirable that the means whereby so unusual a course has been assisted should be widely recognised. There are records of mammary cancer which have remained indolent for fourteen years, and have then been removed by operation, but of these we may be allowed to question the actual nature. In every such instance the indolent character is determined by the condition of the tumour, this never having passed beyond the hard stage of scirrhus; and it is in this relation that Mr. Teale's account is most suggestive. He describes the absolutely fibrous structure of the shrivelled mass, which now occupies the region of his patient's left breast, and from the photograph of it exhibited on Friday evening, it is evident that the contraction of the part has been excessive. It is, in fact, bound down firmly to the ribs, and its progress to this condition, gradual as it was, had been attended with diminution of pain, cessation of the discharge, and improvement of the general health as cicatrisation of the discharging ulcer advanced. The diet prescribed is, by Mr. Teale, adjudged to have been instrumental in aiding this result; an opinion to which general assent was given in the discussion which followed the reading of his paper. Meagre as is the information we possess concerning the part taken by the blood in cancerous disease, there is yet a certain amount of evidence tending to show that it does afford the pabulum on which degenerative material can thrive to excess; and that impoverishment of it is associated with, at least, a modified exuberance of the cellular elements which constitute so essential a portion of the true malignant ulcer. Moreover, the susceptibility to cancer is intimately connected with those conditions of body sufficiently described as “plethoric and fat;” with over-feeding on nitrogenous food; in women with the large breasted state; and with habitual excess in wine and spirits. The observations of numerous careful inquirers, too, have shown that a remarkable increase in the number of white corpuscles may be present with cancer, and it is reasonable to anticipate that the influence exerted over the growth of malignant cells bears some proportion to the deterioration of the blood current itself. Hence the proposal to place restrictions on the amount and quality of food consumed by patients afflicted with cancer, deserves to be more universally made trial of, especially, since, in the latest edition of Aitken's “System of Medicine,” the following directions are given under “treatment” of cancer:—“As a general principle, diet has little or no influence over the course of the disease when once established, except, it may be, that total abstinence from nitrogenous food may starve out the growth and most likely the patient; so that whatever agrees with the patient's digestion may, be safely indulged in. Preven-

tive treatment must be directed to the infant life of those who are hereditarily predisposed." We can hardly, in the face of such evidence as Mr. Teale is able to afford, repose unlimited confidence in this advice; and it will be wiser, within the limits which common sense will suggest, to abstain from the indiscriminate nourishment that sympathy and despair of remedial measures combine to lead the attendant to advise. If cancer is capable of being arrested in its preliminary stages,—and the possibility is no chimera,—then it behoves the profession to give its closest attention to whatever offers promise of achieving this end. If by starving out the *materies morbi* its unlimited propagation can be prevented, then it is the imperative duty of the practitioner, at least to give his patient this chance of arresting the course of disease. And, though as yet there is scarcely a ray of hope that the plan will be successful save with scirrhus tumours, in which the preliminary hard stage has not been passed, still the future may reveal an adaptation of present means for attaining similar results with the more deadly forms of cancer. For the purpose of alleviating the pain experienced by his patient, Mr. Teale bid her have recourse both to morphia and chloral. In consequence of the distressing symptoms exhibited after long continuance of the latter drug its use was suddenly discontinued, and at once relief from mental depression occurred, and was followed by the gradual improvement of the principal disease, improvement which has now persisted for five years. The details of this are interesting in connection with the history of the case, but there can be probably only a remote relation between the chloral and the progress of the cancer, if indeed, any at all. As a contribution to the literature of chloral it is interesting, but it will hardly deserve to be considered as further bearing on the development or course of cancer. Another fact, and one of greater import, mentioned by Mr. Teale, is that for two years his patient had lived on milk alone. This, and the case recorded by Dr. Sutherland, of a patient who for a somewhat less period existed solely on koumiss, will help to a solution of the difficult question "what shall we give our patients for food?" The two cases will deserve attention when in the future the treatment of cancer on principles of abstinence is to be attempted.

One other point referred to by Mr. Teale is worth mentioning. Had chian turpentine, he urged, been employed as a remedy in his case it would have been cited as a marvellous instance of the drug's efficacy. We agree with him, and think also that other cases of cure by chian have perhaps resembled his.

#### THE DENTAL MEETING OF THE GENERAL MEDICAL COUNCIL.

We have received from Dr. Aquilla Smith a letter in reference to the following paragraph which appeared in our issue of the 16th of February:—

"Certain members of the Council, indeed, seem to entertain a strange view of their duty under the Act. The 13th section says: 'The Council shall cause to be erased . . . any entry . . . incorrectly or fraudulently made.' And again, sec. 35 says: 'Any person who wilfully procures . . . himself to be registered . . . by making

. . . any false or fraudulent representation . . . shall be guilty of misdemeanour.'

"These clauses seem sufficiently plain, and yet we find the following pronouncements of speakers on this subject:

"Dr. Aquilla Smith 'assumed that some of these men had acted fraudulently in stating their qualifications, but the Council had nothing to do with that.'

"The President (Dr. Acland) said 'they were not discussing whether persons were guilty of fraud, because that was entirely beyond the province of the Council.'

The words here attributed to Dr. Smith are quoted *verbatim* from the report published by one of our contemporaries, and their verbal accuracy is admitted, but Dr. Smith says they were not his words or meaning. He writes to us:—

"My complaint is that you have attributed to me a statement for which Mr. Macnamara is alone responsible for. I expressed no opinion whether fraud had been committed or not. The garbled quotation, from what I did say, is a very unwarrantable and erroneous charge against me of having 'assumed that some of these men had acted fraudulently in stating their qualifications.' My words were in reply to Mr. Macnamara, who said 'unquestionably there were some who had got on the Register by stating that which was absolutely false, and I added, the Council had nothing to do with that,' (namely, getting on the Register by falsehood), but you suppressed the continuation of the sentence, viz, the motion was simply to strike out the qualification, and if any fraud had been committed, the names would remain in the Register, and they would be just as open to penalty as heretofore."

Dr. Smith requests that we shall withdraw the charge against him of having assumed any of these dentists to be guilty of fraud in stating their qualification, and having in view his explanation of the somewhat ambiguous wording of the report, we are ready to acknowledge that Dr. Smith did not intend to accuse anyone of anything.

But the force of our charge against Dr. Smith and the President and the majority of the Council, i.e., that they did deliberately ignore the duty imposed on them by the 13th section above quoted is not weakened but rather strengthened by Dr. Smith's letter.

We insist that the Medical Council is clearly and intentionally charged with the duty of inquiring as to the *bona fides* and accuracy of each registration entry, and out of the mouth of Professor Humphry we accuse the Council of having cleared away all possible erroneous entries by a stroke of their pen, in order that they may be saved the trouble of such inquiry. It is needless to point out that wholesale elision of these inaccuracies of registration is equivalent to a bill of indemnity to those who were guilty of fraud or misrepresentation, and it is, therefore, not accurate for Dr. Smith to state that the persons who, by such entries, obtained recognition as dentists would be open to penalty and erasure as heretofore.

The sole difference between what Dr. Smith admits that he said, and what he is reported to have said, is, that he did *not* admit that fraud had been committed in any single case, but that he distinctly declined to inquire whether or not it had been committed, and would rather "make a clean slate" by expunging the questionable entries, than undertake the duty which the 13th section imposed on the Council. It is necessary to point out that this expunging of questionable entries advocated by Dr. Smith, means that the Medical Council has taken to its embrace all registrées, fraudulent or not, and has voted them pure, thus finally foisting them on the dento-surgical profession,

and, for the next thirty years, damning the title of "dentist."

To have done so may be legal, but without doubt, it is an act for which the Council may well blush.

### THE GLASGOW ROYAL INFIRMARY.

A CONSIDERABLE amount of rivalry exists between the Glasgow Royal Infirmary and the Western Infirmary in pressing their claims for public support. The following circular has been issued by the managers of the older institution:—

"The managers in making their annual appeal on behalf of this institution, would respectfully submit that there are urgent reasons why they should most reasonably expect that all former contributors who have the ability should materially enlarge their subscriptions, and that many whose names do not appear on the list should come forward in aid of this important work. These reasons may be briefly stated thus:—1. That great improvements have been made in accommodation, in nursing, and in diet. 2. That these improvements, which are only in harmony with the advances that have properly taken place in hospital management, have been and will continue necessarily to be attended with an expenditure much in excess of the revenue which has been derived from all sources whatever. 3. That from causes only too obvious many names which have hitherto been familiar to the managers have disappeared from the list. 4. That alike from its extent and from its objects this institution has paramount claims to public support."

It is alleged that the annual subscriptions to the Royal have considerably diminished since its rival has come before the public; but it is bruited abroad by wicked people that this is of the nature of a pious fraud, for that the Royal is *adding largely to its capital every year*. We have considerable sympathy for the old Royal, for in our recollection the wants of the poor were ungrudgingly attended to at it, and the legitimate rights of the profession properly respected. Things are very different now; the doors of two large hospitals are thrown widely open to all comers, and the descent to poverty and dependence made charmingly easy by all manner of cajolery and the gratuitous distribution of medicine. What would be thought of the argument of a man who opened a magnificent gin-palace, administered to the thirst of all comers, and pointed to the number of his customers at the end of the year as justifying the creation of his establishment? What would people who have to make a living in this manner, say to an institution, possibly supported by the public, and taking the bread out of their mouths? It is felt on all hands that the expense of medical education is grossly and shamefully increasing by the multiplication of unnecessary classes, and that the means of subsistence when one does qualify are diminishing in a corresponding ratio.

The fact of twelve candidates offering for a paltry appointment in Ayrshire, as noticed in our last, is sufficiently significant. The medical profession has rights that ought to be respected. Men used to be able to live comfortably, if not in affluence, by its practice, and we hold that no body of blatant Exeter-Hall philanthropists have the right to deprive the profession of their undoubted privileges. We may sympathise with the managers of crippled Glasgow hospitals; but the fact,

from the professional point of view, is sufficiently patent that ten times too much organised charity exists. Let the people be taught to help themselves; and this can be done by means of provident dispensaries. Then the profession would not be robbed, nor would a mean multitude be simply pauperised.

## Notes on Current Topics.

### Damp Houses.

THE inhabitants of low lying districts, into which water is a frequent and unpleasant intruder, will need no stirring to avail themselves of any remedy they can adopt for a cure of their ills. The physical discomforts that ensue on flooding of houses are more or less easily got rid of, however, the effects they give rise to will probably remain for long to remind the dwellers in damp houses how fraught with risk their tenure is. It is some satisfaction to know that the law admits a remedy against the dishonesty of landlords, who declare that houses they are eager to find tenants for are not subject to inundations, or to the damp, which is detrimental to health. In the Greenwich County Court last week judgment was given against the owner of a house for £50, being the amount paid in advance for twelve months' rent, and £10 expenses incurred in removal by the tenant, who claimed this sum as damage, on account of the house he had taken as a dry dwelling being recently flooded to the height of eleven feet with water. This, however, should not be possible to occur; the State should be in a position to condemn as unfit for habitation any house subject to dampness to an extent likely to injure the health of those who will live in it; and until either the district was so drained as to render floods impossible, or the houses so protected as to remove them from all chance of danger, it should be a penal offence for a landlord to entice, or even permit, human beings to inhabit his property. Then may we hope for a reduction in disease from exposure to damp.

### Royal Medico-Chirurgical Society.

AT the annual general meeting of the Royal Medical and Chirurgical Society, held last (Tuesday) evening, the election of office bearers for the year 1881-82, resulted in the following return:—President: A. W. Barclay, M.D. Vice-Presidents: A. B. Garrod, M.D., F.R.S.; \*S. O. Habershon, M.D.; \*T. Spencer Wells; \*T. Holmes. Treasurers: \*C. B. Radcliffe, M.D.; J. Cooper Forster. Secretaries: R. E. Thompson, M.D.; \*M. Berkeley Hill. Librarians: \*E. H. Sieveking, M.D.; J. W. Hulke, F.R.S. Other Members of Council: \*J. Andrew, M.D.; \*W. Cholmeley, M.D.; C. Hilton Fagge, M.D.; \*S. Ringer, M.D.; \*R. Southey, M.D.; F. J. Gant; \*J. Langton; Francis Mason; J. Morgan; A. Willett. Those gentlemen to whose name an asterisk is prefixed were not on the Council, or did not fill the same office, last year.

### Hospital Nursing.

THE disagreement which resulted in the withdrawal of

five members of the staff from the Rugby Hospital, having been brought before the Birmingham and Midland Counties branch of the British Medical Association, that body has resolved that "Dr. Dukes acted in conformity with the laws of the Rugby Hospital; but that a law practically permitting patients to change their doctors in the hospital is opposed to that professional harmony which is essential to the good working of any medical charity." No doubt this is gratifying to the gentlemen who were opposed to Dr. Dukes, and no doubt also the latter is blameworthy for his share in the proceedings which have brought him under the notice of the Association at Birmingham; but still we inquire concerning the inquiry held by that body, *cui bono*? A more rational amusement was indulged in, though in the same direction, viz., the arrangements for nursing in hospitals, by the Metropolitan Counties Branch Association on Wednesday last, when there was under consideration the management of hospitals. A resolution was there adopted that "It is essential for the proper management of any hospital that the medical staff should be efficiently represented in the government of the hospital." And further, a committee, consisting of the presidents and secretaries of the branch, with Drs. Bristowe, Mouatt, Gilbert, Smith, and Heywood Smith, and Messrs. John Wood, Holmes, Macnamara, and H. C. Burdett, were appointed to collect information bearing on nursing in hospitals. The authority of the British Medical Branch Association must lend weight to proposals for reform in the field of hospital labours, and suggestions coming from such sources will always command considerable attention. In this way the resolutions and discussions are useful, by affording an indication of the dominant opinion in the profession respecting the various matters discussed; information that will by-and-by prove useful. But we venture to think the action of the Association should be chiefly suggestive at present; when it can effect anything directly by its authority, then should it "resolve," and hardly before then.

#### The Medical Society of London.

The general meeting of the Medical Society of London is fixed for Monday, March 7th, when the following list of officers will be proposed for election, to serve during the coming year:—President: W. H. Broadbent, M.D. Vice-Presidents: A. Wiltshire, M.D.; J. W. Barnes, F.R.C.S.; R. Quain, M.D., F.R.S.; R. B. Carter, F.R.C.S. Treasurer: F. Mason, F.R.C.S. Librarian: H. R. Bell, F.R.C.S. Secretaries in Ordinary: T. Gilbert Smith, M.D.; Edmund Owen, F.R.C.S. Secretary for Foreign Correspondence: J. I. B. Berkart, M.D. Council: H. F. Baker, F.R.C.S.; P. Boulton, M.D.; J. C. Bucknill, M.D., F.R.S.; S. Coupland, M.D.; J. H. Craigie; A. E. Camberbatch, F.R.S.; W. H. Day, M.D.; T. S. Dowse, M.D.; Sir J. Fayer, M.D., K.C.S.I.; F. J. Gant, F.R.C.S.; C. Godson, M.D.; D. H. Goodall, F.R.C.S.; A. P. Gould, F.R.C.S.; W. R. Gowers, M.D.; F. de H. Hall, M.D.; M. Morris; Heywood Smith, M.D.; W. F. Teevan, F.R.C.S.; J. G. Thorowgood, M.D.; C. T. Williams, M.D.

#### Mr. Gladstone's Accident.

THE unfortunate mishap to Mr. Gladstone has, we are glad to say, resulted in no very serious ill to the illustrious statesman. The worst consequences are such as must follow the shock to the system sustained by the premier. Mr. Gladstone is of an age at which it is impossible to shake off the effects of any considerable blow, in the way a younger man might be able to. In slipping on the ground, Mr. Gladstone struck the back of his head against an iron scraper, receiving a somewhat severe cut over the occiput. Through speedy and skilled attention, however, this has so far healed as to cause no further anxiety; and all friends of Mr. Gladstone will rejoice to hear that he is now freed from almost every inconvenience produced by the accident which befel him.

#### Cambridge University and Female Students.

By a decision arrived at on Thursday last by the Senate of Cambridge University, lady students will in future be able to claim admission to the examinations conducted by the University, and will be placed according to order of merit in the award of honours. This step has been some time imminent, and will be hailed by the advocates of extending the advantages of higher education to both sexes, as evidence of a more liberal appreciation of the rights of womanhood. The question of admitting women generally to equal rights of graduation with men, can now it must be presumed, be no longer regarded as impossible or unreasonable.

#### The National Society for Aid to Sick and Wounded in War.

AT the close of the Franco-German War of 1870 the above-named Society wound up its affairs, having in hand a balance of upwards of £70,000 to which, since that date, interest has been accruing. This fund was intended to be applied to the relief of British troops in the event of this country being involved in war. The Society no doubt also had the power of granting aid to foreign armies. Since 1870 this country has had some years of almost constant hostilities in one part of the world or another. Thousands of British soldiers have been wounded, and the sufferings of the injured men have in many instances been aggravated by the insufficiency of the assistance provided by the authorities, or by the break down of some branch of the medical department at a critical moment. During each of these recent wars new appeals have been made to the public on behalf of the troops, and committees have been formed to raise and administer funds. Ample evidence has been afforded that the extra succour provided was urgently needed, and was often the means of mitigating much suffering, and of saving life. The National Society seems, however, to consider that charity should begin abroad, and end there, for although it has listened to appeals on behalf of Turkey and Russia, and has made small grants to foreign armies since 1870, it seems deaf to the cry of its own countrymen. We make these remarks specially *apropos* of the new appeal for assistance on behalf of the troops engaged in South Africa. A committee has been formed to raise subscriptions and to send out the men material necessary to supplement the Government provision—which, if not inadequate, is always improved by

such extraneous help. But the starting of a new fund involves delay, so that the help which is wanted at once may not arrive till too late; and the raising and administration of a new fund involves inevitably a great waste of money, and the newspaper advertisements alone often absorbing a large percentage of the amount subscribed. We "want to know why the National Society for Aid to Sick and Wounded in War" is not prepared to do its duty—not only to prevent this waste, but to come forward at the commencement of war with an establishment authorised for immediate work? If the Society consider that they are right in maintaining the attitude of "masterly inactivity" which they have assumed, they are at least bound to enlighten the public as to reasons by which they have been led to form their at present inexplicable resolution.

### Concealment of Infective Disease.

It has been one of the considerations urged by the *Medical Press* in regard to the compulsory notification of Infective Disease in Dublin, that the proposed system of forcing the medical attendant to notify at once the nature of the disease to the corporation might defeat its own object by offering to persons who desired to conceal the infection an inducement to postpone the calling of a doctor because his visit must necessarily be followed by that of the sanitary officer. That there is a reality in this objection is made evident by the most recent public report of the Public Health Committee of the Dublin Corporation, which runs as follows, the italics being ours:—

The attention of the Public Health Committee was drawn to the fact of the concealment of infectious disease, and the serious consequences of neglecting to call in medical aid until the illness is of several days duration. A child recently took ill with fever in a tenement house in Church Street and no medical man was summoned to see the patient, two grown persons have since contracted fever in the same room from the child, and they are now dangerously ill, so much so that the cases could not be removed with safety in the hospital cab, but had to be conveyed on a stretcher to the Hardwicke Hospital. The two last cases were ten or eleven days ill before any medical man saw them, and if left in the room would probably have died, as no person in the house would attend to them. *The fear of incurring the censure of the landlords of tenement houses in many instances appears to be the chief reason for not seeking medical advice in time; with others the dread of removal to hospital is the motive.* Owing to the prevalence of fever in the city, the Public Health Committee would warn the public, especially the working classes, not to neglect obtaining prompt medical advice, and thereby not only increase the chance of recovery, but also prevent the spread of disease in their families.

No doubt the advocates of compulsory notification of infective disease might seek to found upon this statement an argument in favour of imposing stringent regulations to compel the disclosure of such disease when it exists. Far be it from us to dispute the propriety of such regulations, but we think we are entitled to quote the foregoing pronouncement of the Dublin Sanitary Authority as a clear admission that the effect of the very limited arrangements for notification and subsequent sanitation which already exist, is to prevent the medical attendant being called in until too late to be of service to the patient. How greatly would this difficulty be enlarged if, as is proposed, the calling for a medical attendant would, of necessity and in

every case, be followed by the sanitary procedures which tenement landlords and inmates dread so much.

We fully admit that infective disease should be discovered by some means or other, but we urge that no method should be adopted which will cause the doctor to be looked on as a sanitary spy and, therefore, to be kept out as long as possible. If notification of infective disease in Dublin cannot be achieved without consigning the medical attendant to that position, then it will be better that the *status quo* shall remain—bad as it is. But there is an alternative proposition which has worked well elsewhere, and, in our opinion, ought to be tried in Dublin, *i.e.*, to compel the custodian of the patient or house occupier to ascertain the nature of the disease by calling in a medical man and to oblige him thereupon to notify, to hold him strictly responsible for any injury to patient or neighbours from the omission to do so, and to accept no excuse that he did not know the nature of the disease. It would be essential that the energy of the Corporation in the discovery of cases shall be redoubled. Sanitary inspection increased, the causes of death followed up, and prosecutions at once instituted where the nature of the disease has been concealed.

We are confident that a general public announcement that this law would be strictly enforced would, if a few examples were made of delinquents, produce the desired result, and that it would not be necessary, as is proposed, to imperil the lives of patients and sacrifice the interests of the medical profession in order to discover the existence of infective disease.

### The State Medicine Section of the International Medical Congress.

THE following subjects for discussion at the forthcoming meeting of the Congress are announced by the Council of the Section.

*First Day.*—I. Measures by which to prevent the diffusion of different Communicable Diseases from country to country, or within the limits of any single country—*s.g.* (1.) Yellow Fever, Cholera, Plague. (2.) Enteric Fever, Scarlet Fever, Measles, Hooping Cough, Diphtheria. (3.) Syphilis. (4.) Glanders, Hydrophobia, Anthrax.

*Second Day.*—II. Influence of various Articles of Food (not including Water) in spreading Parasitic, Zymotic, Tubercular, and other Diseases.

*Third Day.*—III. Conditions to be imposed upon the legally-qualified Practitioners of one country who may seek authority to practise in another country. IV. Precautions to be taken in Medical Nomenclature and Classification to guard against false Statistical Conclusions.

### The Army Competition.

IN the House of Commons, last week, upon the motion of Mr. A. O'Connor, the following returns were ordered:—Army (Medical Service)—Address for returns of the number of examinations held in London since 1870, inclusive, for appointments in the Army Medical Service. Of the number of vacancies to be filled at the date of each examination. Of the number of candidates who presented themselves at each examination. Of the number of unsuccessful candidates at each examination. And, of the nature and dates of the registered medical

qualifications of each candidate at each examination (the candidates to be designated not by their names, but by numbers or letters). Navy (Medical Service)—Returns of the number of examinations held in London since 1870, inclusive, for appointments in the Navy Medical Service. Of the number of vacancies to be filled at the date of each examination. Of the number of candidates who presented themselves at each examination. Of the number of unsuccessful candidates at each examination. And, of the nature and dates of the registered medical qualifications of each candidate at each examination (the candidates to be designated not by their names, but by numbers or letters).

#### The Metropolitan Hospital Saturday Fund.

THIS, the seventh year of the existence of Hospital Saturday, has attained to a greater success than that of any of its predecessors. The total amount collected being £6,634, that of the previous year £6,152, being an increase of £482. This result certainly affords grounds for congratulation, since it shows that the movement has attained a firmer hold of the working classes. Another gratifying circumstance is that the fund has been more economically managed; the working expenses for the year being 14.66 per cent., whilst, in former years, it has risen as high as 26 and even 29 per cent. The sum distributed amongst 64 hospitals, 31 dispensaries and 5 other institutions, was £5,800. The Committee of Management, which is now chiefly composed of working men, may, if carefully selected, very fairly hope to achieve even a greater success in the future than in the past. The ladies still manifest an interest in the movement, and, by taking the street collections under their care, increased the fund by £1,398. That many hundred ladies should freely tender their services in behalf of the collection year after year, is a circumstance that might well stimulate the efforts of the better classes of artisans in permanent employ; for although they have apparently made an attempt to redeem themselves from the reproach of accepting charity in times of illness, without offering in return anything in a shape of a money equivalent, they have not done all that was expected of them. The Committee, acknowledging the efforts made by a number of dispensaries to open their doors for the accommodation of patients in the evenings, believe more might be done in this direction, and ask for "a little more consideration on the part of managers and medical men of hospitals and dispensaries." It has not entered into the minds of the Committee that any extension of night work must be borne by an already overworked profession, who are usually the last to be considered in these matters, and whose members as a rule receive no remuneration for the time given to hospitals and dispensaries. It would be far more reasonable to recommend those amongst the working classes who cannot attend during the day, to join a Provident Dispensary. Let them by all means enrol themselves amongst the members of the nearest institution of the kind, as, by the payment of a merely nominal sum, they will secure all they desire. We observe that the awards from the Hospital Saturday Fund to Provident Dispensaries are growing small by degrees and beautifully less, so that, probably, the Committee do not see their

way to give encouragement to provident work; it is, however, quite evident that some limit must be set to the endurance of the medical profession in this important matter of medical relief.

#### The Census of the Profession in Great Britain.

FROM the Medical Register for 1881, which has just been issued, we learn that the registered medical practitioners are divided throughout the three kingdoms as follows:—

England ...	15,918	or 69.4	per cent. of the whole.
Scotland ...	3,454	or 15.0	" "
Ireland ...	3,564	or 15.6	" "
Total ...	22,936	100.0	

Within the past year England is represented as having contributed to the profession 667 practitioners, Scotland 267, and Ireland 189, making altogether 1,123 new practitioners. The activity of Mr. Miller in weeding out of the Register the names of dead men and *émigrés* to foreign countries may be judged from the fact that within the last three years 3,260 names of such persons which had remained as errors in the Register were struck out, while in the two years preceding Mr. Miller's revision only 1,354 were got rid of.

We have reason to know that up to the time that Mr. Miller took this work in hand the Scotch Register was in a state of complete chaos, and contained almost as many dead-and-gone practitioners as those actually living.

The correction of the Register is a much more difficult work than might be supposed, and, no matter what effort may be made, it can never, under the existing law, be a strictly correct list of the profession. In the first place, we believe that very many, though it may be and has been made a true record of those who are registered, of the qualified practitioners never register their names at all. A £5-note is, in many instances, a very scarce commodity with the newly-licensed practitioner who has been squeezed dry by curriculum and diploma fees, and we believe that a considerable number of practitioners adjourn the payment of the registration fee, until either they are seeking a public appointment, or have occasion to sue for their fees, these being the only two privileges which a registrée receives for his money. Thus it happens that many qualified surgeons enter into practice and work on for years without any appearance of their name on the list, and, therefore, the number of registrées in any year does not at all truthfully represent the "out-put" of the medical schools of the United Kingdom.

In the second place, the Medical Registrar can make a correction or an erasure only, *a*. In case he has personal knowledge of the death or change of residence of a registrée, or *b*. In case the registrée omits to reply to repeated letters of inquiry. A very assiduous Registrar may, as Mr. Miller has done, acquire personal knowledge by obtaining lists of public medical officials from the Army and Navy and other departments, and may thus amend a multitude of errors in the Register, and it is, we believe, by this means that the book has been made as perfect as it is. As to the erasure of the name of a

person who is too lazy to answer a letter, we take it that such a proceeding is an abuse of the terms of the Act. It is quite right that when the Registrar has good reason to believe that a practitioner is dead, but has not certain knowledge of the fact, he should test the accuracy of his information by sending letters, but it is not right that the names of persons who are believed to be extant should be struck out simply because they are too indolent to reply to the Registrar's communication. Strange as it may appear, it is the fact that a considerable percentage of medical practitioners are so utterly devoid of interest in themselves and their professional position that they will neither read nor answer any letter on any professional subject. It is indifferent to such persons whether they are registered or not, and they wont trouble themselves to reply. Nevertheless, to strike such a person out of the Register, is to introduce one error into its pages.

In our opinion, every qualified medical man should be compelled to register before entering into practice, inasmuch as he ought not to be recognised as a legitimate practitioner unless he shall have duly enrolled himself as such.

#### The General Medical Register for 1881.

WE notice with satisfaction the unusual and praiseworthy alacrity with which the Medical Register for the current year has been issued, and we observe that the improvements in its compilation which we noticed last year are extended still further, so that the volume is now as perfect as it is possible for Mr. W. J. Miller, the General Registrar, to make it. In the first place the whole work has been subjected to the most laborious and careful revision, for the purpose of securing, so far as possible, accuracy of entries, and, at the same time, elegance of typographical arrangement, obtained by spacing the names out better over the page. The several "Medical Acts," up to the present date are arranged and indexed at the beginning of the volume, and on page 68 there is a table showing the exact number of persons registered in the local Registers for England, Scotland, and Ireland. Moreover, the place of registration of each entrant is indicated by attaching the letter E., S., or I. to his name. From a cursory glance at the work, we notice evidences of the removal of many redundant names which had hitherto encumbered the book, and we can fully understand how great a labour must have been the transformation of the book effected by Mr. Miller within the last three years.

#### Accident to Mrs. Kendal.

ON Tuesday evening, about 7 o'clock, Mrs. Kendal was being conveyed in a hansom-cab, when an accident occurred in consequence of the reins breaking. Mrs. Kendal is now suffering from a rather severe scalp-wound on the left side, extending through the left eyebrow, and a large punctured wound nearly through the left arm. The left side of the body is also very much bruised. Mrs. Kendal, who was faint from the loss of blood, was taken into No. 8 Henrietta Street, where she was seen by Mr. Alfred Cooper, and under his advice, removed to her own house on the following day. The scalp-wound, which was brought together by horse hair sutures, has healed by the first in-

tion, and we are glad to learn from Mr. Cooper that this favourite artiste will probably be able to appear again in public on Saturday week, 12th March.

#### Bequest to the Irish Medical Benevolent Fund.

WE learn, with great satisfaction, that this most meritorious charity has received, by the will of the late Dr. Faussett, of Clontarf, near Dublin, the reversionary bequest of £1,000, and also of the house and land upon which he resided. The only restriction placed upon this bequest by Dr. Faussett is, that the proceeds of it shall be applied by the Council of the Fund specially to the relief of Irish dispensary medical officers, their widows and orphans.

#### The late Dr. Peele, of Dublin.

THE Council of the Irish Medical Association, at its meeting on Tuesday, the 22nd, passed the following resolution:—"That the Council of the Irish Medical Association have learned, with the deepest regret, of the untimely death of Dr. Edward Peele, a member of the Council, and they desire thus to record their sense of the loss sustained by the Association in the removal of one so loved and trusted." "That the Honorary Secretary to Council be requested to convey to the relatives of the deceased an expression of the sympathy felt with them in their bereavement by the members of the Council." "That, as a mark of respect to the memory of Dr. Peele, the Committee of Council do at once adjourn."

#### The Inevitable Bill.

ON Wednesday Sir Eardley Wilmot brought in his Bill for the total abolition of vivisection, and put it down for second reading on Wednesday, 23rd March. The names on the back of the Bill are those of Sir Eardley Wilmot, Mr. Samuel Morley, and Mr. Firth.

We trust that the hon. baronet, and his following of feeble-minded doctrinaires, and ignorant old women, will not experience an overwhelming disappointment if their Bill should have to stand aside for a few sessions. But, perhaps, they expect that Mr. Gladstone will make it a Government measure, and that the House will vote "urgency" for it.

#### An Improved Hypodermic Syringe.

DR. SAMUEL WHITALL, of New York, suggests, in the *New York Medical Record*, an improvement on the ordinary hypodermic syringe which will, we imagine, be found serviceable. It consists in substituting, in place of the piston, a piece of rubber tied over the expanded end of the barrel. The arrangement needs little explanation, but Dr. Whitall thus describes the manner of using:—"To charge the syringe, depress the rubber with the index finger, and insert the needle previously attached into the solution to be injected, and then remove the finger; atmospheric pressure at once fills the syringe to the required point. To inject proceed as with an ordinary syringe, depressing the rubber slowly with the index finger till the injection is completed." We remember to have seen a somewhat similar instrument once used for injecting chloral into a dog previous to a vivisection experiment; in ordinary clinical use, however, we have not

previously seen them. The inventor suggests that a needle somewhat coarser than ordinarily employed works better, and he adds that sometimes a bubble or two of air enters the connective tissue during the operation; the emphysema, however, he asserts, is quite harmless.

#### Tottenham Sanitary Association.

THE Tottenham Sanitary Association have issued a Report of Proceedings for 1880, which shows that good work has been done by it on behalf of the Tottenham district. The creation of similar district associations would result in considerable general sanitary progress.

DR. THOMAS ROBT. HAMILTON MOOREHEAD, of Enricle, Cotehill, has been appointed to the Commission of Peace for the County of Cavan.

Two wards at St. Thomas's Hospital were opened yesterday (March 1st) to the public who can afford to pay for surgical and medical advice. Mr. Walter Edmonds, F.R.C.S., has been appointed medical officer to these wards.

THE U.S. Army Medical Museum and library contains 20,000 specimens, very completely illustrating military surgery and the diseases of armies. The library contains 51,500 volumes and 57,000 pamphlets relating to medicine, surgery and allied topics.

THE *New Zurich Zeitung* says that Dr. Giacconi, a physician in Airolo, has discovered that the sickness from which workmen engaged in excavating tunnels, &c., suffer so frequently is due to peculiar parasites (*Aukylostomæ*), which make their way into the intestines of persons employed under the earth.

An inquest held at Nottingham on Friday on the body of James Clay, it was shown, as the result of a *post-mortem* examination, that death had been caused by eating American pork affected with trichinæ, and a verdict to that effect was returned by the coroner's jury. Fifteen other persons in the locality have suffered from the effects of pork purchased at the same shop, but they have recovered.

PARIS has still a very high mortality from small-pox and typhoid fever, 41 victims of the former, and 76 of the latter, died there last week. In the same period 69 deaths from typhoid occurred in St. Petersburg, and 40 in New York. Small-pox is prevalent in Philadelphia, whereat 54 died from the disease last week, and 30 in Vienna; in the latter city it seems to be steadily abating in virulence.

MR. KANCHIRO TAKAKI, F.R.C.S. Eng., a Japanese, who received his professional education at St. Thomas's Hospital, and was admitted a member of the Royal College of Surgeons in 1878, and a Fellow in 1880, on his return to Tokio was appointed Chief of the Imperial Naval Hospital and a member of the Committee for the Preparation of a Japanese Pharmacopœia, and to attend all the foreigners, with their families, employed by the Imperial Naval Department.

THE rates of mortality last week in the principal large towns of the United Kingdom were—Newcastle-on-Tyne 17, Birmingham 18, Bradford 18, Portsmouth 18, Leicester 19, Wolverhampton 19, Sheffield 20, Brighton 20, London 22, Plymouth 22, Salford 22, Hull 22, Norwich 22, Bristol 23, Oldham 24, Nottingham 24, Edinburgh 24, Glasgow 25, Leeds 25, Liverpool 25, Manchester 28, Sunderland 28, Dublin 38 per 1,000 of the population.

SCARLET fever showed the largest proportional fatality in Bristol, Edinburgh, and whooping cough in Leeds and Glasgow. Of the 25 deaths referred to diphtheria, 10 occurred in London, and 7 in Glasgow. The death-rate from fever, principally enteric, was highest in Dublin, Sunderland, and Liverpool. Small-pox caused 56 more deaths in London and its suburban districts, and one in Manchester, but not one in any of the other large towns.

THE rates of mortality in the principal foreign cities, having an estimated aggregate population of 13,000,000 persons, were, according to the latest official returns, as follows:—Calcutta 31, Bombay 32, Madras 35; Paris 31; Geneva 21; Brussels 25; Amsterdam 28; Rotterdam 34, The Hague 26; Copenhagen 30; Stockholm 29, Christiania 17; St. Petersburg 54; Berlin 25, Hamburg 29, Breslau 29, Munich 30; Vienna 38; Buda-Pesth 38; Rome 28; Naples 28, Venice 36, Lisbon 35; New York 31, Brooklyn 26, Philadelphia 23.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE CHAIR OF PATHOLOGY IN THE UNIVERSITY OF EDINBURGH.—*On dit* that Dr. W. T. Gairdner, Professor of the Practice of Physic in the University of Glasgow, is a candidate for this chair.

THE EDINBURGH MEDICAL JOURNAL.—The February number of this ably conducted periodical is an excellent one. Professor Fraser concludes his interesting paper on "A Case of Malignant Disease (Sarcoma) of the Lung;" Hughes Bennett, of London, "A Statistical Inquiry into the Action of the Bromides in Epilepsy;" Dr. Halliday Croom, "The Systematic Use of Antiseptics in Midwifery Practice," to which system Dr. Croom seems an uncompromising adherent; and Dr. Byrom Bramwell, an excellent clinical lecture "On Intra-Cranial Tumours." Of the reviews, that of Dr. Fancourt Barnes' translation of "Martin's Atlas of Obstetrics and Gynæcology" will rivet most attention. Dr. Barnes, the reviewer shows, is not altogether the man who ought to attempt a German translation. The Hyperboreans, however, manage these things better. Why did not Dr. Barnes employ a lady to do his translation for him?

DR. JAMES DUNSMURE, JUNR., has been appointed Medical Officer of the Trades' Maiden Hospital in succession to the late Dr. Andrew Wood.

ABERDEEN.—MEDICAL OFFICER OF HEALTH.—As we recently mentioned, the Town Council of Aberdeen have resolved upon appointing a Medical Officer of Health, whose whole time will be devoted to the duties of the office. The salary is £300, with a free house, coal, and light, at the Epidemic Hospital. It is more than probable that the salary

will ultimately be increased, when the benefits arising from the presence of such an official will become apparent. Great credit is due to Dr. Beveridge for his enlightened and public spirit in this matter. The candidates are Dr. Aubrey Husband, of Edinburgh, and Dr. Frank Ogston, Aberdeen. Without disparaging in the least the claims of the latter gentleman, the former possesses special recommendations of fitness for such an office which cannot easily be put aside. The appointment of Dr. Aubrey Husband would be acceptable to the profession, and we feel persuaded would ultimately be of signal benefit to the ancient city of Aberdeen.

**THE LATE PROFESSOR SANDERS.**—The funeral of the late Professor Sanders took place on Wednesday, the 23rd ult., and was largely attended. A few minutes before 2 o'clock, a large body of students, who had been fortunate enough to have followed his systematic course of pathological teaching and clinical demonstration within the walls of the infirmary, gathered in front of the house. Under the superintendence of one of the class-assistants, the young gentlemen formed themselves six abreast in front of the hearse, and were then seen to number about 180. The procession proceeded towards Dean Cemetery. Among the gentlemen present were: The Lord Provost, Principal Sir Alexander Grant, Professors Gairdner, Glasgow; Balfour, Douglas MacLagen, Grainger Stewart, Spence, Turner, R. T. Fraser, Annandale, &c. About forty members of the medical profession practising in Edinburgh were present.

## Medico-Parliamentary.

HOUSE OF COMMONS—MONDAY, FEB. 28TH.  
SCOTCH DIPLOMAS.

SIR T. LAWRENCE asked the Vice-President of the Council if he was aware that the highest qualification of the Royal College of Surgeons, Edinburgh, viz., the Fellowship, was to be had without examination, and even in absentia, by persons holding lower qualifications, on payment, and by a process of vote by ballot; if he was aware that the highest qualification of the other two Scottish medical corporations, viz., the Royal College of Physicians, Edinburgh, and the Faculty of Physicians and Surgeons, Glasgow, was given on similar terms; and if he could inform the House whether such a system had ever been the subject of representation or remonstrance by the General Medical Council.

MR. MUNDELLA said he had reason to believe, with regard to the Royal College of Surgeons of Edinburgh, that the Fellowship was to be obtained by persons already members upon the terms stated in the question. He understood that the Fellowship was not a licence of the qualification, but a distinction conferred by the College on a three-fourths vote. He was unable to obtain any information in regard to the Faculty of Physicians of Glasgow and Edinburgh. The question of what the hon. gentleman called higher titles would form part of the inquiry into the working of the Medical Acts which the Government proposed immediately to institute.

### NOTIFICATION OF INFECTIOUS DISEASES.

The following letter appears in the *Medical Times and Gazette* of Feb. 19th:—

SIR,—I observe that the propriety of compelling the attendant physician to notify the occurrence of infective disease to the sanitary authority is a question open for debate in your columns. We are threatened in Dublin with such a law, and I oppose it on these grounds:—

a. That the ministrations of a physician are a confidence not to be violated except for extreme cause. This you may, if you please, call sentiment, but in Ireland it is a principle of great influence upon the minds of physicians.

b. That, in the very numerous instances where it is desired to conceal the disease to avoid the application of sanitary law,

the compulsion to notify may produce the four following ill results:

1. That if I notify in opposition to the wish of my employer I may expect to get my *congé* at once.
2. That, fearing notification, the householder will keep me outside his door until the patient is dying for want of medical aid.
3. That if I declare my honest belief that the disease is infective, I shall be immediately hustled out, and a dishonest practitioner got in, who will call it herpes, or febricula, or a stomach rash.
4. That when cases of infective disease prove fatal, either with or without the services of a physician, they will appear in the Registrar-General's death return under a false name, thus vitiating our vital statistics.

My further objection is—

c. That by no possible means can any penalty be enforced on the dishonest practitioner for omission to notify, for he can always plead that he did not recognise the disease; and no man can be fined £5 for an error of diagnosis.

These objections arise in a special degree in Ireland, as compared with England or Scotland. At the eastern side of the Channel, the first attendant on a patient is almost always a general practitioner, who is not paid for his services at the time, but keeps an account, and cannot be got rid of until that account is settled—*ergo*, the feelings of his employer on the notification question are not of immediate moment, and it is not possible either to dismiss him at a moment's notice, or call in a less candid adviser.

In Ireland we are paid at each visit, and, if we do not give satisfaction, may be discarded at any moment in favour of some one whose diagnosis is less decided, and sanitary zeal less marked.

Now, Sir, I have submitted these objections to the system to a great many advocates of notification, and the only answer I have elicited were—1. Oh! for the public good the profession must give way; and 2. All these difficulties are imaginary.

Such replies are unsatisfying, and I solicit others more convincing.

I am, &c.,

ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.

## Obituary.

PETER D. HANDYSIDE, M.D., F.R.C.S.I., F.R.S.E.,  
OF EDINBURGH.

UNIVERSAL regret will be felt by old pupils of the Edinburgh School of Medicine now scattered in all parts of the world when they hear that Peter Handyside is no more. Old and cherished associations have been thus rudely snapped asunder, which even the knowledge that the subject of our notice had reached the fulness of life will not altogether assuage. Peter Handyside may be said to have died in harness, teaching to the very last his favourite subject, to which he had devoted a long and honourable life. Born in Edinburgh in 1808, he was the son of the late William Handyside, W.S., and brother of the late Lord Handyside, a Judge in the Court of Session. Having graduated at the University of Edinburgh, he visited the schools of Paris and Heidelberg, where he completed his training for the medical profession. For some time he was a pupil of the late James Syme, and imbibed from that renowned teacher the enthusiasm for anatomical research which gave direction and point to his future labours. On returning to his native city from the Continent, Dr. Handyside was associated with Professor Spence and Dr. Lonsdale, late of Carlisle, in the conduct of a large anatomical class in Surgeon's Square. Finding, however, that, from his position as surgeon to the Royal Infirmary his private practice rapidly increasing, he resolved to devote himself entirely to this, and accordingly gave up teaching engagements. His health, however, failing, he was obliged to seek rest in continental travel. On returning once more to Edinburgh, on the removal of Dr. Struthers to Aberdeen in 1863, Handyside became the Lecturer on Anatomy in the Edinburgh extra-mural School of Medicine—a post which, as we have just said, he held till his death, on February 21, 1881. He was the author of numerous works, relating prin-

cipally to his favourite branch of study, that of anatomy and surgery. Among these are "Outlines of Anatomy," "Engravings and Description of the Blood Vessels," "Experimental Essay on Absorbent System," "Osteo-Aneurism," "Sterioptixinae Class of Fishes," "Encephalocoele," "Theory of Death from Air Admitted to the Veins," "Arrested Twin Development," "Acrania," "Cyclo-Cephalian Form of the Etmoccephaloids," "Subarachnoid Serous Lac," "Transitions in the Foetal Heart," "The Polyodon Gladius," "Shall I study Medicine?" "Jubilee Chronicon of the Medical Chirurgical Society," "On Dearth of Candidates for Army Medical Department," and various contributions to the Transactions of the Medical Chirurgical Society. Dr. Handyside was the founder and warmest supporter of the Edinburgh Medical Missionary Society. As with other men in his position, honours came to Dr. Handyside, and he was a member of many learned societies both at home and abroad; but it will not be on account of these alone that Peter Handyside claims the affectionate remembrances of those who knew him. Dr. Handyside, by universal consent, was a man incapable of any low or mean act, and a little incident which took place just before his death finely portrays the exquisite delicacy of feeling which always characterised him, and which embalms his memory:—It appears that on his medical attendant calling one morning just before his death, and inquiring as to the manner in which he had passed the previous night, poor Handyside, with that gracious, manly bearing which marked all his actions, thanked his friend for the delightful night he had been the means of securing him. On inquiry, however, it was found that the night had not been that of the calm which he had described, but that he had silenced complaint to relieve the regret of his friends and adviser.

Dr. Handyside leaves a widow and two daughters to mourn his loss.

## Novelties.

### "THE GRADUATED PROBE,"

BY J. A. McMUNN, L.R.C.P., L.R.C.S. ED.

This probe consists of two distinct portions of equal length—one of which is grooved and converted into a director, while the other, with which we are more immediately concerned, is graduated to its full extent. The graduated scale represents three inches, and their subdivisions into eighths of an inch. The head of the probe is round the body cylindrical. The probe proper is three inches long and the director three inches also; the whole combination being exactly six inches. The value of the probe to the surgeon and medical jurist is obvious. The depth and extent of any wound are revealed at a glance, and with the greatest possible precision. The extent of cavities in necrosis, &c., may be readily determined. Its applicability is almost universal, while the combination adopted enhances its general utility. The accompanying woodcut will render the description more intelligible.

The instrument may be obtained in London of Messrs. Arnold & Sons, West Smithfield, and of their Agents in all parts of the United Kingdom.

We may add that the gold medal at the Sydney Exhibition for excellence of manufacture has recently been awarded to this firm.

### DATE COFFEE.

In our last we stated that there was considerable stir in the commercial world on the subject of Date Coffee, and that our opinion had been asked as to its suitability for invalids and for persons of weak digestion. As, however, it is our invariable rule not to express this without first practically testing the merits of an article, we handed samples of the Date Coffee to Dr. Muter, the public analyst for Southwark, Lambeth, &c., and annex herewith his Report. We may preface this by stating that Date Coffee is prepared after a process invented by a Mr. Henley, which consists of submitting the date fruit to artificial heat until it becomes in a

measure calcined. It is then crushed or ground, fruit and stone together, and sold in the proportion of three-fourths ground dates and one-fourth ground coffee, at one shilling per pound.

It would be absurd to pretend that for flavour and aroma the public will prefer Date Coffee to fine Mocha, and, moreover, it lacks that stimulating principle, caffeine, which in a great measure has made our customary breakfast beverage popular. It has, nevertheless, some points in its favour. Firstly, it is what it pretends to be, ground dates pure and simple; it is cheaper than good coffee, it needs less sugar, and it is slightly aperient, which, to persons of sedentary habits, will be its strongest recommendation. In other respects the comparative analysis shows it to differ but little from ordinary coffee.

#### ANALYTICAL REPORT.

Analysis of a sample of Date Coffee received from the Editors of the *Medical Press and Circular* on the 19th February, 1881, and also a sample of ordinary coffee for comparison:—

	Genuine Coffee.	Date Coffee.
Moisture	8.15	2.15
Caffein	.74	none
Tannin	1.67	1.60
Sugar	None	6.60
Colouring and extractive matter, soluble in water	19.94	21.15
Soluble ash	3.50	1.80
Insoluble matter	71.00	66.80
	100.00	100.00

JOHN MUTER, Ph.D., F.C.S.

South London Central Public Laboratory,  
Kennington Cross, London, S.E.

### DANGER OF PILOCARPINE IN ECLAMPSIA.

DR. ALBINI, after experiments on dogs and rabbits draws the following conclusion (*Il Morgagni*). 1. Duboisine and eserine instilled into the eye of the living animal produce this effect, which continues even after death. 2. Applied to the eye of a dead animal, they act for many hours after death, but in inverse ratio to the age of the animal and the time that has elapsed between death and the application. 3. If a little before death duboisine and atropine have produced mydriasis, the eye after death is still sensible to the action of eserine, provided it be fresh. Inversely the pupillary stenosis, due to eserine, is changed to mydriasis by duboisine or atropine. 4. Equally concentrated, a solution of duboisine is more active than that of atropine and of eserine. Thus if two eyes of the same animal submitted, the one to duboisine, the other to eserine, the latter becomes mydriatic more easily by duboisine than by atropine, whilst the former sooner loses its pupillary stenosis under eserine than if it had previously been acted on by atropine. 5. The duration of the action of eserine is shorter in the cadaver than in the living body; that of duboisine on the contrary, like that of atropine, is longer, that is to say, more persistent.

### ATROPINE, ESERINE, AND DUBOISINE.

M. SANGER publishes three cases of eclampsia treated by subcutaneous injection of pilocarpine in two centigramme doses (*La Presse Medicale Belge*). The crisis seemed to yield, but the patients experienced suffocative symptoms from inability to swallow the saliva. Two died. Pilocarpine is a very dangerous remedy in these cases, as the coma stops the reflex actions necessary for the swallowing of the saliva.

## NOTICES TO CORRESPONDENTS.

MEDICUS.—Letter in type, and will appear probably in our next.  
DR. REDMOND is thanked; he will receive a private note.

## POISONING BY GAS BATH-HEATERS.

SIR,—A paragraph has recently appeared in your Journal respecting the death of Mr. C. F. Deacon, of Anerley, Surrey, who was poisoned by the noxious vapours arising from the gas apparatus by which his bath was heated. A Dr. Turner is reported to have stated at the inquest that gas-burners were highly dangerous, and he advised that the use of them should be discontinued. To this sweeping condemnation wide publicity has been given. I have already received numerous letters from persons who have been alarmed by it, and I trust therefore you will permit me the right of a public reply. It is perfectly true that some of the methods now in use of heating water for baths by means of gas are not safe. None of the class known as instantaneous water-heaters for baths should be used in any room unless the products of combustion can be perfectly carried away at once by a flue, although small sizes may be safely used in sculleries and lavatories for heating small quantities of water quickly. They are especially dangerous in bath-rooms, which are, as a rule, small and close, and the danger increases with the power of the heater. Although I am a patentee and manufacturer of these instantaneous heaters, I have never used them or recommended their use for baths. This, however, does not warrant a condemnation of all systems, and the one I have adopted for heating baths is such that no danger or unpleasantness can arise from its use. Even in the smallest and most confined bath-room without ventilation, the fumes given off by the burner used are so exceedingly small in quantity as to be incapable of causing the slightest harm. I cannot therefore permit Dr. Turner's remarks to pass without protest. It is evident that he has formed his opinion without possessing a full knowledge of his subject, and intending only to condemn the system he knew, has at the same time condemned others which, his remarks prove, he can never have seen.

I am, yours respectfully,  
THOMAS FLETCHER, F.C.S.

4 and 6 Museum Street, Warrington,  
Feb. 26th, 1881.

["\* It affords us pleasure to insert this letter; Mr. Fletcher has done more to further scientific research by his inventions for laboratory use than any other manufacturer we know of; his gas furnaces and heating apparatus are formed on scientific principles and, from practical knowledge, we can speak of them with unqualified praise. In giving his evidence at the inquest referred to, Dr. Turner did not specify any particular appliance; it would have been better under the circumstance had he done so; he probably referred to the many common apparatus in use, which are certainly fraught with considerable danger in small closed bath or other rooms. Mr. Fletcher need not anticipate any injury to his reputation, as Dr. Turner's strictures do not apply to him.—Ed.]

AN ANXIOUS ONE will find his query answered in another column, present number.

FULHAM.—Dr. Brewer is chairman of the Asylums Board, whose meetings take place on each alternate Saturday.

DR. BOWER (Springfield).—With pleasure.

MR. CARTWRIGHT will please receive our thanks.

ST. LEONARDS.—The hospital was, we believe, founded in the reign of Stephen, and flourished under—for those times—a moderately rich endowment for two or three centuries. Very little is now left of the ruins, and, of the foundation trust, history says nothing.

INTERNATIONAL COURTESIES.—The Editor of our excellent contemporary the *Philadelphia Medical Times*, must, when in this country, have induced our friend Dr. Milner Fothergill to try his weight, for in a review of a book of this latter gentleman, *Phil. Med. Times*, Feb. 12th, 1881, he says: "The recipe for goose-pudding is rather strong for a sick stomach less capacious and well trained when in health than is that which ministers to the two hundred and eighty pounds of its genial North-of-England producer,"—i.e., Dr. Fothergill.

DR. A. M. H. will receive a private note.

BOYCOTTING THE "MEDICAL PRESS."—Commenting upon the recent childish exhibition of spleen by the Editors of the *Glasgow Medical Journal*, the *Glasgow News* says: "The practice of boycotting has received an extension in Glasgow hardly to be expected by those outside of the medical faculty. The *Medical Press and Circular* informs its readers that the *Glasgow Medical Journal* is regretfully compelled to remove the former paper from its list of exchanges. Now the *Medical Journal* is the organ of the Glasgow 'faculty,' and this may be taken as an exhibition of feeling at the strictures of the elder 'periodical. Whether the black-balling of the *Press and Circular* had anything to do with the hard hitting of its correspondent, and the 'reflex action' of these again to induce the boycotting, are subjects that an outsider can hardly appreciate. 'Can heavenly minds such 'high resentment show'?"

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—This (Wednesday) afternoon, and on Friday, at 4 p.m., Prof. W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."

OBSTETRICAL SOCIETY OF LONDON.—This evening, at 8, Specimens will be exhibited by Dr. Godson and others.—The President, Dr. Matthews Duncan, will deliver his Inaugural Address.—Dr. Robert Barnes. "On so-called Missed Labour, with a Case in illustration."

EPIDEMIOLOGICAL SOCIETY.—This evening, at 8, Surgeon-General John Murray. "On the Influence of Fairs, Floods, Famines, and Seasons on the Development and Diffusion of Cholera in India."

PATHOLOGICAL SOCIETY OF LONDON.—Thursday, March 3, at 8½ p.m., the following specimens will be shown:—Unilateral Hypertrophy of Head and Face; Tumour of Spinal Cord; Sacral Tumour containing

Foetal Structure; Congenital Sacral Tumour (card); Syphilitic Disease of Skull; Malformation of Heart; Cancer of Prostate; Epithelioma of Bladder; Vesicle Calculus from a Dog (card); Cranium and Brain of Hydrocephalic Adult (card); Case of Leucoderma (living specimen).

THE ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—Monday, March 7th, at 8 p.m., Mr. Charters White on "The Histology of the Gustatory Organs of the Tongue."—Casual communications by Mr. James Parkinson and Mr. R. H. Woodhouse.

## VACANCIES.

Ardee Union, Collin Dispensary.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, March 10.  
Bath Royal United Hospital.—Resident Medical Officer. Salary, £100, with board. Applications to the Secretary before March 11.  
Braintree Union, Essex.—Medical Officer. Salary, £80, with the usual extras. Applications to the Clerk of the Union by March 4.  
Glasgow University.—Examinerships in Medicine: 1. Physiology; 2. Clinical Medicine; 3. Clinical Surgery. Fee attached to each office, £40. Applications to Dr. Kirkwood, 145 West George Street, before March 15.  
Guildford Union, Surrey.—Medical Officer of Health. Salary, £200. Applications to the Clerk of the Union before March 9.  
Kent and Canterbury Hospital.—House Surgeon. Salary commencing at £80, with board. Applications to the Secretary at Canterbury before March 25.  
South Dublin Union, South City Dispensary.—Medical Officer. Salary, £125, and £25 as Medical Officer of Health. Election, March 8. (See Advt.)  
West Norfolk Hospital.—House Surgeon. Salary, £107, with board. Applications to the Secretary at Lynn before March 4.  
York Friendly Societies' Medical Association.—Resident Medical Officer. Applications to Mr. J. Brown, 1 Park Street, York, by March 5.

## APPOINTMENTS.

ACLAND, T. D., M.B., M.R.C.S., a House Physician to St. Thomas's Hospital.  
BUTLER, H. P., M.R.C.S., L.R.C.P., House Surgeon to St. Thomas's Hospital.  
CARPENTER, A. B., M.R.C.S., House Surgeon to St. Thomas's Hospital.  
COHEN, A., B.A., M.B., B.Ch., Senior House Surgeon to the Metropolitan Free Hospital.  
COLLIER, M. P. M., M.R.C.S., L.R.C.P., Assistant House Surgeon to St. Thomas's Hospital.  
HOSKINS, W., M.B., C.M., Medical Officer for the Second District of the Poole Union.  
HUTTON, H. R., M.B., a House Physician to St. Thomas's Hospital.  
LUNN, J. R., L.R.C.P., M.R.C.S., Resident Accoucheur to St. Thomas's Hospital.  
OWEN, I., M.A., M.B., M.R.C.P., Lecturer on Materia Medica to St. George's Hospital.  
POOLEY, T. A., B.Sc., F.C.S., Analyst for the County of Essex.  
SMITH, R. P., M.B., B.S., L.R.C.P., Demonstrator of Practical Physiology in the Medical School of St. Thomas's Hospital, London.  
SWALE, H., M.R.C.S., L.R.C.P., Junior Assistant House Physician to St. Thomas's Hospital.  
VINRACE, F., M.R.C.S.E., House Surgeon to the Queen's Hospital, Birmingham.  
WALTERS, F. R., M.R.C.S.E., Senior Assistant House Physician to St. Thomas's Hospital.

## Births.

KELLY.—Feb. 9 at 12 Plough Road, London, S.E., the wife of Bernard Kelly, M.D., of a daughter.  
ROBERTS.—Feb. 9, at Upper Bathmines, Dublin, the wife of Browne Roberts, M.D., of a son.  
WALKER.—Feb. 23, at Shrubland House, Hackney, the wife of W. Newman Walker, M.R.C.S.E., &c., of a daughter.

## Marriages.

MACKENZIE—GORDON.—Feb. 22, at St. Mark's, Notting Hill. Surgeon-Major John Mackenzie, M.D., A.M.D., to Ashton Bostock, only daughter of Surgeon-General C. A. Gordon, M.D., C.B., Honorary Physician to her Majesty the Queen.  
SPENCE—BENNETT.—Feb. 23, at St. Matthew's Church, Redhill, Jar es Beveridge Spence, M.D., Medical Superintendent, Burntwood Asylum, Lichfield, to Elizabeth Roebuck, eldest daughter of Richard Bennett, Esq., of Redhill, Surrey.

## Deaths.

AVENT.—Feb. 21, at Lansdown Place, Plymouth, Nicholas Avent, M.R.C.S., late of H.M. 60th Regiment, aged 46.  
BENNETT.—Feb. 16, at George Street, Devonport, James Bennett, M.R.C.S.E., L.S.A.L., aged 64.  
BEVAN.—Feb. 18, at Rye Lane, Peckham, George William Bevan, Surgeon, formerly of St. Ives, Cornwall, in his 79th year.  
BOGG.—Feb. 18, at his residence, Burlington Villas, Altrincham, Thos. Wemyss Bogg, M.B., M.R.C.P., aged 44.  
BRADY.—Feb. 24, at 88 Harcourt Street, James Wm. Brady, M.B., Dub. Univ., L.R.C.S.I., eldest son of Dr. James Brady.  
BURN.—Feb. 20, at The Cedars, Shirley, Southampton, of heart disease. George Burn, M.D., C.B., Inspector-General of Hospitals and Fleets (retired), aged 70.  
HANDYSIDE.—Feb. 21, at Lansdowne Crescent, Edinburgh, Peter David Handyside, M.D., F.R.S.E., Lecturer on Anatomy, Royal College of Surgeons, Edinburgh, aged 57.  
HENDERSON.—Feb. 12, at Keith, J. L. Henderson, L.R.C.P. Ed.  
HURMAN.—Feb. 17, at Eastover, Bridgwater, H. B. Hurman, M.R.C.S.F.  
LAWLOR.—Feb. 24, at Deaford, Templeogue, Agnes, the wife of J. S. Lawlor, M.D., in the 24th year of her age.  
MACKENNA.—Feb. 24, at 31 Great Marlborough Street, London, John W. MacKenna, M.D., L.F.P.S.Glas., in his 78th year.

### CERTAIN CONSIDERATIONS REGARDING CHOLERA AND FEVER. (a)

By SURGEON-GENERAL C. A. GORDON, M.D., C.B., Honorary Physician to the Queen.

(Concluded from page 181.)

14. Contagion plays relatively an inconsiderable part in regard to cholera and fever in the tropics. With regard to the former disease, while there are circumstances which support the theory of transmission by this means in respect to individuals and communities, there are other, and equally numerous, which point to an opposite direction, the result being, that in one set of instances it is beyond question that the disease was thus transmitted, in other instances it is equally indubitable that it was not so communicated.

It has been pointed out (b) with regard to a succession of outbreaks of cholera in India, that in places where the epidemic was most intense, the disease was often confined to very circumscribed localities, and points of immunity are mixed up with those which suffered all over the country to a varying extent in different districts; also that in the affected and non-affected localities the conditions of the people were alike, and free communication went on among them. (c)

As a matter of fact, it is within the experience of many observers in India that in times of cholera a general tendency to bowel affections prevails; that in other respects

(a) Read at a meeting of the Epidemiological Society of London, 2nd February, 1881.

(b) In the last report by the sanitary commissioner with the Government of India, namely, for 1879, Dr. Cunningham expresses strongly his views that neither propagation by men, that is, contagion, nor fouling of water by cholera discharges, can account for the diffusion of cholera. *Medical Times and Gazette*, February 6th, 1881. It is desirable to bear in mind the difference between the communication of cholera in isolated cases, and the general diffusion of that disease as an epidemic.

(c) Paper by Inspector General Lawson. See Transactions of the Epidemiological Society, 1879, p. 91.

the health standard of masses is impaired, and that during the continuance of such conditions, depressants of all kinds, medical, physical, or moral, are to be avoided. Exceptions which occur do not alter the rule as it stands. The recurrence of cholera periods is familiarly recognised as a cholera wave. There are also fever years, unhealthy years, during which diseases of whatever nature, external or internal, assume severe or peculiar types. All these phenomena pointing to the operation of a cause above and beyond a specific undiscoverable entity, transcending, but it may be, including the latter.

The theory of pandemic waves merits careful attention, for the reason, on the one hand, that it appears to be but another expression for epidemic influence; on the other, on account of the high position as an investigator, enjoyed by its leading advocate. According to him, its nature and mode of action are difficult to define; it may act by rendering the system more susceptible of the ordinary causes of disease, or it may act upon those causes themselves, giving origin to a more virulent or new form of disease.

The existence of contagious fevers (a) in India is placed beyond doubt. Such a fever has been described in 1815 and 1820 in Kattywar, Kutch, and Guzerat; (b) more recently the occurrence of malarial fevers as epidemics has been recorded as happening at intervals of ten years, (c) the circumstance of the disease on such occasions, being contagious or not, being much debated. Then comes the

(a) With regard to what is called *enteric* or *typhoid* fever, Dr. Murchison says that hospital experience lends little support to the doctrine of contagion. Dr. Wilks had never seen a case where it was contagious among the nurses of Guy's Hospital, nor had Dr. Peacock in those of St. Thomas's Hospital. Messrs. Bristowe and Holmes had seen two cases in which it was contagious in the Royal Free Hospital. Dr. Collie is of opinion that it is contagious. Dr. Sharkey believes contagion to be more frequent as a cause than is supposed.

Dr. Chevers gives "Transactions of Epidemiological Society," vol. iv., part iii., p. 338, particulars of an epidemic of relapsing fever in Zulusfyre in 1852-3, of violent remittent in Upper Provinces in 1816, in other parts of India in 1836-7, 1855, 1860, 1864.

(b) First Special Report, p. 8.

(c) Macnamara, p. 301.

Pali plague, the Maba Maree, the great sickness (a) in 1834-5, 1849, 1851-2, 1860, 1876-7, its contagiousness apparently limited to Race. But with regard to the ordinary fevers of India, such as came under my notice, out of 175 cases investigated, not one was traced to either contagion or infection.

15. *Summary.*—In summarising the remarks now made the following points present themselves when viewed from the aspect from which I consider the data thus examined:—The distribution of the diseases named in different portions of India on the occasions described is to be accounted for neither by the theory of specific poisoning alone, nor by that of contagion alone. There is every reason for believing that, although no actual relationship exists between the diseases cholera and small-pox, the same or a similar law applies to the manner of their prevalence as epidemics. Between cholera and malarial fevers a relationship is indicated as existing alike in respect to causation and phenomena. Both these diseases in India present a general relation to season. Both in India and in England a relation appears to exist between the type of prevailing fever and locality. Bowel affections generally, in India and elsewhere, present a relation to season and locality; this relation as defined as that of vegetation to the same circumstances. In endemic fevers intestinal lesions and those of the abdominal tissues occur as complications in protracted cases. Cholera in India occurs under a variety of circumstances, and in different manners, but neither furnish a specific name applied to particular cases, as indicating one particular manner of causation. Fevers vary in phenomena and intensity according to conditions, geographical, climatic, and individual. Among our soldiers in India fevers in the mass and in individual cases are less sthenic in type than they formerly were. Reasons for this circumstance are assigned. Specific poisons are of two categories as described. Innocuous liquids can, by artificial means, become converted into poisons; hence analogy indicates the likelihood of corresponding changes being effected by means of vital action. But diseased liquids do not necessarily communicate their particular disease, either when inoculated or when swallowed. Certain diseases named, which are propagated by infection or contagion, are induced by particular combinations of conditions. Fever, in some of its types and forms is of this class; so is cholera. Between these diseases themselves, and with regard to several others named as occurring epidemically, an affinity is indicated. The expression malaria is but another term for climatic influences. The existence of organisms peculiar to malaria has yet to be confirmed. No specific poison is necessary to account for the phenomena of Indian fevers. The theory of specific poison does not explain those in "typhoid" or "enteric" fever. It is opposed as insufficient by a number of authorities. General insanitary conditions predispose to disease, but do they to any one specific disease more than another? It is not established that such is the case. Polluted air induces certain diseases, but not necessarily a specific form of fever. In China air intensely polluted is compatible with health and activity. The theory of local pollution, if sufficient to account for the occurrence of some epidemics is altogether insufficient in respect to others. Although contaminated water may induce cholera, the occurrence of that disease is not always thus accounted for. Water induces cholera after it has become epidemic, not before. The relation of water supply to cholera in India is not established by recent observations. Very striking instances are adduced where the use of extremely foul water has not resulted in fever, enteric or other; while instances are recorded particularly in places where cholera is endemic or epidemic, of cases of that disease following the use of contaminated milk, instances are related of infants suckled by women ill of cholera, yet they not becoming affected by it. Cases said to have been of typhoid fever due to the use of diseased meat were subsequently stated to have been cases of trichinosis and sausage poisoning. Although specific ty-

phoid, like several other forms of fever, may be conveyed by means of milk, this circumstance by itself fails to explain the epidemic diffusion of that disease. As a rule, cholera has no relation to age. In India and the tropics generally the young and the lately-arrived suffer more by endemic diseases than the older in age and residence. Race appears to affect liability to certain special diseases in particular countries; not so in others. Infant mortality of Europeans in India is excessive. Individual conditions and habits predispose to particular forms of disease and complications. Climate influences the geographical distribution of disease, and determines its type and incidence. Although cholera has undoubtedly been propagated by means of masses of persons and individuals in numerous instances, there are others equally numerous in which it has not been so. (a) Fevers of particular kinds in India may be propagated by means of infection, but of the cases investigated by me not one was thus accounted for. (b)

Thus, by the light I possess, have I endeavoured to pass in review, some out of many points which, to me, appear most important in reference to the occurrence and prevalence of the diseases named. I am aware that I have the great misfortune to entertain an interpretation of phenomena and evidence before me, different, in several respects, from that of some very eminent authorities. I am also aware that in my manner of interpreting those phenomena, I am in accord with other eminent authorities and most careful observers; the numbers of both decidedly on the increase, not alone in this country, but more especially in India, China, and elsewhere, among our vast foreign possessions and settlements.

I have restricted my remarks to opinions only. I, however, give references in the shape of foot-notes, the better to facilitate access to the sources of those opinions. I trust that in the paper now read I have, to some extent, at least, succeeded in my endeavour to indicate the grounds upon which views expressed by me have been formed, as also the process by which I have myself been led to consider from the data before me, that the theories of specific poison and contagion are, of themselves, insufficient to account for the phenomena of the diseases to which I have had the honour to solicit your attention, and that of the Epidemiological Society.

#### OPHTHALMIA IN WORKHOUSE SCHOOLS. (c)

By THOMAS M. DOLAN, F.R.C.S., Ed.,

Medical Officer of Halifax Union Infirmaries, Yorkshire.

INHERITED diatheses, as scrofula and syphilis, insufficient and unvaried feeding, overcrowding and imperfect ventilation of school-rooms and dormitories, unwholesome clothing, and other insanitary conditions, are recognised as leading elements in the development of follicular granulations and contagious ophthalmia, amongst workhouse children.

The following narrative confirms our existing evidence on the causation of epidemic conjunctivitis, and shows its close dependence upon hygienic defects.

A few extracts from my report book will show you the previous defective conditions which led up to the annoying and troublesome outbreak of ophthalmia which is the subject of this paper.

(a) "Hygiene of Cholera," par. 11, p. 99; also p. 150-159.

(b) As expressed by the older authors, so now--

"Neither infection, nor terrestrial malaria, nor mineral vapours, nor exhalations from dead animal matter, nor intemperance of season or weather, nor famine, scarcity, or unwholesome food, nor crowding of the living—the healthy or sick, nor filth, nor stillness, humidity, warmth, or other conditions of the air, nor depressing emotions and passions, nor any physical, social, or moral vicissitude, will singly account for epidemics; but that the association of several of these causes in various grades of predominance is necessary to their occurrence, diffusion, and continuance."—Copland's "Dictionary of Medicine," 1858, p. 773.

(c) Paper read at Yorkshire Branch of British Medical Association.

Under date of 24th of January, 1876, I reported to the board of guardians that the schools, covered playground, sleeping accommodation, were deficient in ventilation, and again, under date 29th of April, in consequence of the appearance of *impetigo contagiosa* amongst some of the children, I had to make another report, anent some radical defects in the playground. I then said:—

“At present it is almost a reservoir of foul air, from the closets inside it; this air circulates into schools, day rooms, and bed rooms, the children are consequently breathing poisoned air.”

The guardians did everything in their power to remedy these defects, but yet there was a perceptible effluvia vitiating the air; the cause of which remained for some time undiscovered.

In January, 1877, a few mild cases of scarlatina appeared, with another memorandum to the following effect:—

“I beg to draw attention to the children’s bedding. It is in a very bad and unhealthy condition; a number of children wet their beds, saturating the flocks with their urine. This affects the atmosphere of the rooms, especially when heat is produced at night by the warmth of the children themselves.” The guardians at once acceded to my recommendations. With such a history, and knowing as Brudenell Carter says:—“That when granulations are once developed they are like tinder, to which any accidental circumstance may apply a spark,” you will not wonder at the following report, dated August, 1877:

“Owing to a threatened outbreak of ophthalmia amongst the children, it is desirable

1st. That suspected cases should be isolated, those positively affected being sent to the hospital.

2nd. The boys and girls should have separate towels.

3rd. Shades should be supplied to those affected.

4th. Some old linen should be provided, to be destroyed after use.

5th. All children in the schools should be placed on an improved diet.

6th. An extra number of pauper helps should be sent to assist the paid nurse.”

These are the facts leading up to the outbreak which I shall briefly describe, though I need not enter into minute details of the symptoms of this affection, as they are no doubt familiar to you all. For fuller information I may however refer anyone interested in the subject or unacquainted with the disease, to the *Lancet* report on the Epidemic of Ophthalmia, at the North Surrey Schools, Anerley, in August, 1872, or to Brudenell Carter’s work on “Diseases of the Eye.”

In the beginning of August, 1877, there were eighty-five children classified on the books of the Halifax Workhouse. In the first week five children were brought under my notice, suffering from tender eyes, which was attributed to dust, but which I saw was dependent on other causes; they were at once sent into hospital.

On the 11th I had nine children under treatment, and by the 23rd the total number affected reached forty-five, after which we had no more fresh cases, so that the progress of the epidemic was extremely short, severe, and limited.

The cases varied in intensity, some simply complained of tenderness, whilst others suffered from the dangerous discharge, so characteristic of the disease. I may say from my experience of eleven years as workhouse medical officer that nothing has given me so much trouble as the management and treatment of these children. This arose first from the difficulty of classifying them, separating the slightly affected from the badly diseased, the boys from the girls.

1. From the varying ages of the children, which ranged from three to twelve.

2. From difficulties arising about the application of lotions, towels, bathing, &c.

3. From the bad constitutions, and inherited diatheses of the children themselves.

Nothing is easier than to give orders and to issue directions; nothing is more difficult than the carrying of them out, especially when you have to depend upon such help as is ordinarily placed at your disposal in a workhouse, and have to deal with a number of children.

Cleanliness and bathing are most important, but difficult of attainment. I secured the separate washing of the children by a very simple contrivance, which I adapted on a former occasion when the children had skin disease.

In the ordinary bathing arrangements for children, I should not like to say how many are washed in the same water, as this depends upon the nurse in charge. To obviate this, I constructed a kind of flexible hose and jet, somewhat similar to that used in shampooing, by means of which hot and cold water could be turned on, so that as each child stood in the bath, a fresh supply of hot or cold water was administered to him or her. Then came the difficulty about towels.

At general bathings each child had a towel, which was not used again, until it had passed through the disinfecting laboratory.

As regards ordinary ablutions there was less difficulty, as the lavatory arrangements were good, and it was possible to keep the towels of the children separate.

This is most important, for much mischief may be caused by the indiscriminate use of towels, as for instance, when some are mildly affected, and others severely so.

The application of lotions is a matter of great difficulty, for as the disease was not equally severe in all of them, the applications varied in strength and character; for some, an alum lotion of four grains to the ounce was sufficient, whilst for others I employed a solution of nitrate of silver, two grains to the ounce.

Then came the application of some emollient, to prevent sticking of the lids, for which I had to depend upon the nurses; in the severe cases I, of course, had to apply the lotions myself, in some cases to touch the lids with sulphate of copper.

The constitutional diatheses of the children complicated affairs, but this I simplified by placing all upon improved diets, with cod-liver oil as a luxury, whilst for some I ordered Parrish’s chemical food.

As a recompense for all the annoyance and trouble I had, there was this satisfaction: the children all recovered without any permanent injury to their eyes, and there were no ill-effects afterwards. The process of recovery was slow, as I kept the children under treatment and observation a very long time, knowing the danger of discharging children, before the cure was complete, and I dreaded the repetition of the epidemic, for one was enough for a life. It was three months before I was free.

I may add that the schools had been thoroughly cleansed and fumigated, and the guardians tried to carry out my recommendations, though the results for a short time were not satisfactory.

The sequel is instructive and will be particularly interesting to the author of “Dangers to Health,” Mr. Teale.

The last case went back about the middle of November. There was no recurrence of the disease, but yet the children’s health did not improve. I had to make another report, and the children were removed from the buildings.

We had put down a new and expensive system of drainage, and one large 18-inch pipe ran close to the children’s covered play ground, into which some smaller pipes converged. We thought it well to open up this drain at various points, and we found, just at the back of the play-ground and running along the back of the school, a most disgraceful piece of scamped work.

The 18-inch large drain was full from end to end, the connecting pipes were not jointed, but rough holes had been bored, into which the smaller pipes were inserted; the level or fall was in the wrong direction to avoid cutting through the rock. In many places the pipes were

broken, and the ground saturated with filth. Here was the secret, buried beneath the soil, hence sprung the foul air which had been poisoning the children and which had caused so much suffering and annoyance.

The guardians were put to considerable expense about this drain. Since that time the schools have been in fairly good condition and I have had no outbreak amongst the children.

I may add that the guardians have adopted one very wise provision, though, at the same time, attended by certain risk, viz. :—

They now send their children to the Board Schools. Up to the present, with the most satisfactory results, not only as regards their physique but their morale.

One word as to the immediate cause of the outbreak. Our workhouse children belong to the floating population. Children are coming in and going out almost daily; so that it is quite possible some child may have been admitted with the disease in its latent stage.

With this hypothesis, and under the conditions I have described, we need not wonder at the result.

### NOTES ON PNEUMONIA.

By THOMAS MOORE SUNTER, M.D., T.C.D.,  
M.D. Oxon.;

Formerly of the 7th Fusiliers.

"UNTYPIC" pneumonia having been under discussion at a recent meeting of the Clinical Society (a), eminent members of the medical profession taking part, it has occurred to me that the present occasion might not be inopportune to introduce notes of two cases that occurred in my practice, now close upon thirty-three years ago.

No. 1.—J. M., 7th Fusiliers, æt. 21, English, sanguine temperament, robust constitution (labourer before enlistment), admitted to hospital at Waterford, May 5th, 1848, with headache, hot skin, frontal pains, and white, trembling tongue. Ordered an emetic immediately; diaphoretic mixture with antimony afterwards.

6th.—Six leeches to forehead. Spoon diet.

7th.—Complains of pain in left side of chest, but breathing is healthy.

8th.—Cough and diarrhoea. Breathing 48, abdominal; pulse 120, compressible; short, gasping, dry cough; decubitus on left side, and on face; dull percussion and fine crepitation over right lung anteriorly. V. S. ad thirty-two ounces *pestea*, *cucurbitulæ cruenta thoraci dextro*; six glasses put on at once, and about twelve ounces of blood got. Calomel and James's powder every four hours, and a drachm of mercurial ointment rubbed into right side.

9th.—Pergat; blood buffed and cupped; very firm coagulatum.

10th.—Mouth unaffected; respiration 24, diaphragmatic; pulse 96, fuller, soft. Bronchial breathing and reverberation of voice under right clavicle; dull percussion and rough respiration same side posteriorly. Heart beats very audible under right clavicle. Omit pills of calomel and James's powder; to have instead pills of calomel, opium and tartar emetic every second hour, and to rub a drachm of mercurial ointment into right side every four hours.

11th.—Slight mercurial fœtor; gums swollen. Pulse 86; respiration 24, less diaphragmatic—intercostals take more part in it. Conjunctivæ and skin have slight yellow tinge. No expectoration; retention of urine. Symptoms rapidly improved after this, and he was discharged quite well, June 2, and has continued well.

I considered and treated this case as one of "fever with cerebral lesion" till third day after admission, on which cough and hurried breathing caused me to examine chest,

when real nature of attack was disclosed. The physical signs *immediately under right clavicle* made me somewhat apprehensive of a cavity in apex of right lung, and we know how difficult it often is to distinguish between acute phthisis and acute pneumonia. Slight jaundice was present in this case—an occasional symptom of pneumonia—attributable, according to Dr. Walshe, to pressure on minute bile ducts, from obstructed right heart and vena cava.

No. 2.—E. H., 7th Fusiliers, æt. 24, Irishman (labourer before enlistment), robust, previously very healthy, admitted to hospital at Waterford, May 18th, 1848, for a *boil on forearm*.

24th.—Seized with nausea, rigors, headache, hurried pulse and breathing. Six leeches to forehead and diaphoretic mixture; spoon diet, *potus tartari*.

27th.—Pulse 126, soft. Slept some time last night, and raved some; quite rational to-day. Tongue moist, white fur in centre. Often at stool during night; watery discharges. No pain in head. No other symptoms remarkable.

28th.—Did not sleep last night. Continue mixture. 9 p.m.—*Abradentur capilli capitis*.

29th.—Called to him at six this morning. Rattles in throat; did not sleep last night; raved and tore his sheets. Pulse 156, very weak; eyes dull, conjunctivæ pale, contracted pupils; tongue moist, almost clean; livid lips; perspiration on forehead, which is livid also; soft, moist skin; tympanic abdomen. Omit diaphoretic mixture. Port wine, camphor and ammonia; blister to epigastrium; chicken broth. 5 p.m.—Sank gradually and died at 3.30. Sensible to the last.

Post-mortem; right lung adhered to right pleura by a layer of light yellow lymph, easily peeling off; upper and middle lobes closely adherent, sections of a mottled colour, like black points in grey marble; lower lobe congested; two-thirds of anterior edge of middle lobe healthy. Left lung adhering to left pleura costalis by tendinous bands about an inch and a-half long, exactly like chordæ tendinæ of heart; upper and middle lobes healthy (a large quantity of reddish frothy fluid issued from section of upper lobe), lower intensely congested, sections presenting black spots, apparently coagulated blood. Heart large; walls of left ventricle remarkably thick and muscular; consequent, probably, on abnormal action, caused by obstructed pulmonary circulation (?). Other organs not remarkable with exception of stomach, mucous membrane of which, at larger curvature had an arborescent appearance, of a deep-red colour, mixed with dark mahogany-looking spots. I never suspected a pulmonary complication in Case No. 2, looking on it throughout as one of fever, in which cerebral lesion was chiefly to be apprehended. The man had no cough, pain in side, or expectoration—though I am aware that these signs may be absent, and yet pleuritis or pneumonia be present—in fact it was only of his head he complained.

A Waterford physician of experience happened to come round the ward with me the day before death, and he agreed with me as to the nature of the case. No. 1 was in hospital same time as, and next bed to, No. 2.

Observations (January, 1881).—A change has taken place in the treatment of pneumonia since the above cases were under observation. The masterly inactivity, so to speak, which at present obtains (speaking comparatively), recalls a reply of Trousseau to the writer, when, in 1857, at the Hôtel Dieu, he asked how he would treat a case of arachnitis in a very young subject, who occupied one of the beds: "Le moins je fais, Monsieur," he said; "le mieux je fais!" Whether this change has arisen as a consequence of the improved state of medical knowledge, or that the human constitution is less tolerant of depletion, might not be so easy to say. The germ of it is, I think, contained in a remark of Graves during the period I acted as his clinical clerk at Sir Patrick Dun's Hospital, more than forty years ago, viz.:—"It is of the last importance to cure disease with the least possible loss of blood," an idea he carried out when he "fed fevers."

(a) Vide *Medical Press*, Dec. 15, 1880.

But, though the supporting system is now in vogue, who shall with certainty say that a sthenic cycle will not again girdle these islands—that the now all but dethroned remedies, venesection, antimony, and mercury, may not recover their “pride of place,” and physicians of the future be found treating pneumonia like their forefathers. (a)

I regret that force of habit, or force of routine, did not lead me to make a stethoscopic examination of the lungs in Case No. 2. It would, no doubt, have been *indicative*, as it was in No. 1, and the means of my adopting somewhat similar treatment. Whether this would have been followed by a similar result I know not.

No. 2 was a treacherous case—grave symptoms running their course with rapidity. The treatment of No. 1 may appear “heroic” in these days. But there is the authority of Sir Thomas Watson, for the statement in the latest (1871) edition of his lectures, “that though multiplied experience now shows mercury in pneumonia, not to be commendable practice, yet *different cases require different modifications of treatment, for which no particular rules can be laid down*,” and Sir Benjamin Brodie (b) says: “Soldiers are of strong constitution, good health, not much advanced in life, and from the situation in which they are placed, may well be supposed to have a power of throwing off morbid poisons, and of bearing depletion, not enjoyed by the majority.” It crossed my mind that Case No. 2 might, in reality, have been one of blood-poisoning. It was admitted for a boil,—i.e., an unexaggerated “carbuncle,” of which Brodie writes: “It seems to me as if there was something like a poison in the circulation in this disease.” (c) The treatment of No. 2 was the “expectant treatment,” as it is, I believe, called by Continental physicians and others. Though unwittingly adopted by me, the result was not encouraging. Finally, the heart beats being so audible in No. 1, immediately under right clavicle, did not necessarily indicate solidity of subjacent lung. In my experience they are occasionally audible in same situation, when lungs are healthy.

## Clinical Records.

### MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. E. STAMER O'GRADY, M.R.I.A., A.B., M.B., Ch.M., Univ. Dub.,

Fellow (by Exam.) Member Surgical and Dental Courts of Examiners, Royal College of Surgeons.

Of four cases of epithelioma which were operated on during the month of January, (d) the trouble was labial in three. Two of these patients (cases A. and B.) were non-smokers.

#### *Epithelioma of Lower Lip—Three Cases.*

A. A wiry-looking man of small stature, *æt.* 60, had had for fourteen months a warty growth on the right side of the lower lip; for three months the trouble had been increasing rapidly, and had come to involve slightly the angle of the mouth. Removal was readily effected by a somewhat modified V operation, right limb of the cut being lengthened and curved. Though a very considerable sized mass was thus excised, yet thanks to an exceptionally full lower lip the soft parts required but little lateral detachment to form a most respectable mouth. The wound united by the harelip

(a) Although as much a convert as most men to the modern practice of treating disease without directly abstracting blood, I entertain an idea that some change will yet take place, whereby the lancet may again come into use, although to a more limited extent than in former years.—Sir W. Ferguson, “Practical Surgery,” 5th edition, 1870.

(b) “Lectures on Pathology and Surgery.” London, 1846.

(c) *Op. citat.*

(d) These cases were coincident with the period of the occurrence of the severe and long-continued snow. The exceptional rigour of the weather seemed to exercise a more or less decidedly retarding influence on repair in each of them.

needles and one catgut suture on the red border; resulted well; the patient being discharged from hospital 24 days after operation.

B. A healthy-looking man, a herd, *æt.* 55, had suffered for years “off and on” from a “crack” in the centre of the lower lip; this of late had become surrounded by a rapidly extending indurated mass, from which a tail-like process ran along the red border of the lip towards the right angle of the mouth. The central portion having been dealt with by a large V, the caudate prolongation was readily included between two parallel incisions and removed. The edges of this portion of the cut having been whipped together by a continuous suture of carbolised catgut, the central portion of the wound was closed by three harelip pins with a stitch on the red border so arranged as to include both segments of the split right side. A capital result was obtained, the patient leaving hospital in a fortnight.

C. This patient looked considerably older, at least ten years so, than the 63 he returned as his age. He was much in the habit of smoking a short thick-stemmed pipe. The disease was of some two years' standing, having begun originally as a wart near the left angle; this, of late, grew rapidly, till, on admission, the mass was larger than the ungual phalanx of a man's thumb. A similar operative procedure and dressing as in the preceding cases obtained an admirable result. It would have been difficult, when the patient left hospital twelve days afterwards, to detect that he had been operated on at all.

*Epithelioma of Left Temple*, one year growing, and about size of palmar aspect of the thumb, quite free from any deep attachments, and unattended with gland complication. Patient, a man aged over 70 years, and who had been rather a free liver. Removal was readily effected by circumscribing the mass with two elliptical cuts, one above, the other below it, when the finger was easily passed through the areolar tissue from one incision to the other, completely raising the diseased portion. The hemorrhage would have been very profuse were it not for the careful way pressure was maintained by the finger tips of assistants all round the circumference of the wound. Five notably large vessels were tied, but the entire length of the cutaneous cuts, on removal of the digital pressure, continued to bleed uninfluenced by the application of styptics. Uniting the wound by three hare-lip needles, with the further application of compresses soaked in Friar's balsam, and bandaged in position, commanded the flow. The primary progress of the case was very satisfactory, but in 48 hours after the operation the two posterior needles were withdrawn, in consequence of local swelling, and the dressing being moist. Next day, an old chest trouble had become much aggravated by an acute graft into a severe attack of bronchitis, whilst locally there threatened a slight erysipeloid state of the wound. This rapidly subsided, discoloration and swelling being limited to the immediate neighbourhood of the wound, which then cleaned and began to repair. Throughout this period the constitutional phenomena were mild. During the eleventh day after the operation, at a time when the patient seemed to be in every way greatly improved, and to be doing most favourably, in the afternoon, whilst reading the newspaper, he was suddenly seized with a severe rigor, which lasted a considerable time. During it he became markedly delirious and mental cloudiness remained in diminishing degrees for a couple of days. Shortly after the commencement of this attack, as he rallied to stimulants, the pulse was 130, and the temperature 102.2°. Next day there was a rather smart diarrhoeic attack, when both pulse and temperature became reduced considerably. Three days later improvement was very manifest, though a good deal of annoyance was now caused by a small swelling which had long existed at the root of the right side of the neck. This had become inflamed, it suppurated, and subsequently opened. The bronchitic attack, though paroxysmally very troublesome, was relieved, when the severity of the weather mitigated, he rapidly improved in health. The local repair, though steadily progressive, was very slow, a minute streak of the operation wound being still unhealed when he returned home 33 days after the operation, at which time the abscess in the neck had not entirely closed either. Some portion of this long stay in the hospital was, however, consequent on his seeking an apparatus for a large and difficult to be kept up hernia. As dressing to the wound, boracic acid in glycerine and an ointment of iodoform, pitch, and vaseline answered best.

*Anal Fissure with both External and Internal Piles, and Sub-*

*sequent Formation of Fistula.*—A stout, florid, remarkably healthy-looking woman, mother of 12 children, had been suffering for over three months from the symptoms of fistula recti in an aggravated form. Examination, which could only be practised under an anæsthetic (chloroform), showed at the right side of the orifice of the gut an ulcer similar in size and shape to the face of a split almond, its lower end being flanked on each side by an external pile. These were nipped off and the fissure divided with a bistoury. Some days subsequently, and attended with much increase of suffering, internal piles, which also co-existed, became painful and bled freely. Two large bunches were tied 30 days after the division of the ulcer. Acute local suppuration of severe type supervened, resulting in suppurative and formation of a fistula, which communicated with the ulcer. A week after tying the piles the fistula was divided. Improvement was now rapid and complete, the patient being able to leave the hospital 17 days later in perfect health. (a)

*Extensive Sloughing Phagelæna.*—A strong healthy looking young man, a pavier, presented at the dispensary with the prepuce swollen to the size of a large pear, in places mottled, but, for the most part, of a deep black colour; a state of affairs which had come to pass the patient said within 48 hours. Next day the already nearly detached mass was readily wiped off, showing considerable destruction of the glans. The urethral orifice stood out prominently. The whole diseased surface bled profusely, and was dressed by the introduction of a catheter, and application of strips of lint, soaked in muriate tincture of iron, firmly bandaged on. Repair was rapid; the wound being nearly healed, when patient was discharged eight days later. He continued under observation as an extern for some time, during which no secondaries appeared, nor did the orifice of the urethra show tendency to contract.

*Amputation through shoulder* for extensive epithelioma of the hand and forearm; diseased lymphatics distinctly traceable up the limb. A couple of enlarged glands being above the inner condyle, and an indurated mass, as big as a turkey egg, in the axilla. Patient, *æt.* 72, the remains of a fine hearty man, much reduced by the hæmorrhages, pain, and above all, by the perpetual bad smell, pressed earnestly for the operation. A week after admission there was smart arterial bleeding, which was, with difficulty, controlled by local means. Under all the circumstances of the case, it was considered right, at consultation, to respond to the patient's very urgent desire. Removal of the limb was effected by deltoid and internal flaps. As the latter was being cut, the thumb and fingers of the operator's left hand following the knife, kept secure grip of the vessels (the subclavian being also commanded with a padded key), of which eleven were secured by carbolised catgut, the operation having been almost bloodless. From the internal flap, all affected gland masses were removed, and a seemingly healthy wound obtained. This was dabbled well with a 40-grain solution of chloride of zinc. Due provision was made for drainage by a large tube covering the wound, as well as by a pledget of lint prepared with turpentine, which had been applied to an oozing portion of the surface. The wound was brought together by seven points of suture, the scapula and surrounding parts being duly supported. The operation was wonderfully well-borne, followed by but little shock; nourishment was well taken; sleep obtained; bowel secretion continued abundant; pulse and temperature rates but moderately disturbed. On the evening of the third day, however, a change began to manifest itself; henceforward the patient grew feebler, and, without any notable symptom, died rather suddenly on the morning of the fifth day after the operation. Examination of the stump showed much repair had already been effected. A good deal of it was united; the suppurative action where present was of healthy type. (b)

(a) Coincidentally, or nearly, with this patient's presence in the Hospital, it happened that there were three other similar, though less formidable cases, viz.:—*A.* Multiparous female, *æt.* 50, with external piles and fissure on left side. The former snipped off and latter divided. Recovery in 9 days. *B.* Multiparous female, *æt.* 42, the ulcer placed posteriorly; division; followed by recovery in 16 days. *C.* Male labourer, *æt.* 50, much older looking, a hard living man. Fissure running into external pile on left side; divided; snipped off; cure in 12 days.

(b) Scapula humeral disarticulation at Mercer's has been attended with excellent results, this being the only fatal case out of the nine which have occurred in this Hospital since Mr.

*Amputation of Thigh.*—Patient, a man well over three score, 14 years previously he had hurt his left knee, which had since, "off and on," been bad, the trouble eventually degenerating into well-marked suppurative arthritis. The joint being greatly swelled, and the seat of intense suffering; the femur was thickened for some inches. Amputation by the long anterior rectangular flap method was effected at junction of lower and middle third of thigh, a periosteal curtain being preserved. Seven vessels were tied with carbolised catgut, and the wound well dabbled with the chloride of zinc solution. Four hours subsequently the stump was brought together, a large drainage tube being placed across it. Despite the patient's enfeebled condition, the operation was well rallied from, and save for the anxiety more than once caused by chronic chest trouble, progress continued very satisfactory. The drainage tube was removed in a week, and in three weeks from the time of the amputation, the stump was quite healed. The patient being now at least ten years a younger looking man. His subsequent stay in the hospital was merely to get provided with, and accustomed to, an artificial limb.

## Transactions of Societies.

### SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, Feb. 4, 1881, in the Albert Hall, Royal College of Surgeons; Dr. MAPOTHER presided.

Mr. E. WILLS-RICHARDSON, hon. sec., read the minutes of the previous meeting, which were signed.

Adjourned discussion on Mr. Wheeler's communication:—

A RECORD OF CASES TREATED ANTISEPTICALLY, AND OF CASES TREATED ACCORDING TO LISTER'S METHOD, WITH REFERENCE TO CASES TREATED WITHOUT THE USE OF ANTISEPTICS.

Mr. HENRY FITZGIBBON, who had moved the adjournment of the debate on Mr. Wheeler's communication, which was read at the previous meeting, said the question raised in that paper, as it appeared to him, was one between the efficiency of extreme cleanliness and what had been termed Listerism. The medium adopted by Mr. Wheeler, and which he had seen most successful in his hands for procuring cleanliness in the treatment of his cases, was a solution of carbolic acid of some strength or other—he believed of no definite strength, and that he sometimes used it strong and sometimes weak. To that system of cleanliness it was suggested by a speaker who criticised his paper to apply the term "Wheelerism," in contra-distinction to the system adopted by Lister, and termed "Listerism." But cleanliness of treatment was not at all peculiar to Mr. Wheeler. Indeed, he thought the adoption of the precaution of extreme cleanliness in the treatment of surgical cases of late years was very much due to Lister's exertions in the advocacy of his own system. And, again, cleanliness has been adopted with the greatest success many years ago in Philadelphia by the late Surgeon Norris, whose medium of procuring that essential to surgical success was soap and water, not carbolic acid. He believed Norris's successes were perhaps as great as those of any other surgeon before or since. Mr. Wheeler had laid some stress upon facts which he, too, had seen—viz., that in some cases where operations had been performed, such as rectangular flap amputation of the thigh, the flap being insufficiently supplied by vessels, mortification of the flap had taken place. Now, it was unjust to Lister's method to attribute that accident to the use of carbolic acid spray, or of Lister's carbolised gauze, or, in short, to the legitimate and proper use of Listerism. Those operations were generally performed with the assistance of Esmarch's bandage, and he entertained what amounted to more than a suspicion that the contraction of the vessels by that bandage produced total anæmia of large flaps for a considerable period. Consequent on the unnecessary delay

O'Grady's connection with it. In one of these cases the entire scapula was removed, as well as the limb. This, and two other cases, where likewise the entire scapula was taken away in combination with excision of the head of the humerus, all recovering well, and the two latter patients preserving useful limbs.

of surgeons in dressing their stumps because there was no hemorrhage going on, strangulation was kept up for a greater length of time than was good for the flap, causing a great amount of suffering, which could not be in any way attributed to the use of carbolic spray, even at a strength of 1 in 20. Another point had been raised against Listerism, that it could not be good to expose a large wounded surface to the cold spray. In the *British Medical Journal* published since last meeting, Bantock gave a number of cases treated with a solution of 1 in 40, and even weaker, as he took exception to the use of solution of 1 in 20, and he thought that applying it in ovariotomy to the peritoneal cavity and to the peritoneum might be injurious. No doubt injuries arising from the use of the spray in those cases were often attributable to neglect in the preparation of the lotion used. In ovariotomy he had himself remonstrated against the use of cold carbolic lotion, and made probably with cold water of a temperature little above freezing point. The spray ought to be heated to a temperature of 80° before being used, particularly in cases where the peritoneal cavity was open. Another point with respect to the use of the spray was one on which Lister himself laid great stress—that the carbolic acid used in the preparation of the lotion should be pure; for, if not, the operator's hands would suffer seriously from it; whereas, when pure, even at a strength of 1 in 20, irritation of the skin was not produced. The smarting of the hands was so characteristic of impure carbolic acid that, when he felt it, he always rejected the lotion. That was the result of using carbolic acid of inferior quality, or—he was not at all sure—of the lazy habit of some chemists in keeping it in solution with glycerine; so that the spray was not carbolic acid of 1 in 20, but carbolised glycerine, or almost pure carbolic acid, sufficient to produce cauterisation of the skin and irritation about a wound. Mr. Wheeler objected that the carbolised gauze excited eczema on the skin. So it would, if the gauze was badly made; but not, if it was properly made. Gauze should be prepared with resin, oil, and hard paraffine (1 oz. carbolic acid, 2 oz. linseed oil, 4 oz. resin, and ¼ lb. hard paraffine). With that mixture the gauze was saturated, and run perfectly dry. If the gauze had too little oil, it would produce eczema; but if properly prepared, it would not, though remaining for weeks on the surface of the body. With respect to the antiseptic properties of Lister's method, he had seen cases—and some in his own practice—where there was a certain amount of sloughing in the flaps, arising either from tight bandages, or from the pressure of Eschsch's bandage during the operation; but there had been no small injuries to the patients in the immediate neighbourhood, although portion of a flap or the margin of a wound might slough off. That he could not say of some of the cases under the care of his worthy colleague, Mr. Wheeler; for, although they had led ultimately to what might be termed brilliant surgical results, nevertheless, during the process of healing they had been most offensive, so much so that some of his colleagues thought it judicious to remove patients in a critical condition to a more distant bed. Still, by persistent washing and cleanliness, those cases had ultimately resulted in most excellent surgical results. He was, himself, a strong advocate of Lister's system, adopting it invariably in cases which he considered suitable for it. There were cases which he did not consider suitable for Listerism. In cases of chronic abscesses, which were those Lister had most largely cited, he considered that the use of the carbolic acid spray, as Lister adopted it, would actually retard recovery.

Mr. J. K. BARTON, speaking on the general question, which he took to be the merits or demerits of the spray in dressing open wounds, said he had, without premeditation, an experiment lately before him. About two months ago he had excised the knee-joint in a little boy, set. 7 or 8, in many respects an unfavourable case. On the first or second dressing, a day or two after the operation, the child showed an unconquerable aversion to the spray, crying himself almost into fits. On that account he thought it better to omit the use of the spray. He did so for a fortnight or three weeks, and the operation was turning out favourably, but there was a free suppuration from several old sinusses. Under the circumstances he tried the spray to check the suppuration with marked result, and the spray was adopted for the remainder of the dressing. In the same way he had tried Lister's treatment on sinusses that would not heal, but under that treatment almost immediately dried up and healed. With regard to the sloughing of flaps, the cases which he saw were those before using the antiseptic method,

and therefore whatever produced the unfortunate result, it could not be attributed to any change in the manner of dressing.

Mr. Wm. THOMSON thought that anyone who believed in antiseptic surgery could not sit quietly without expressing dissent which he did himself emphatically, from the views put forward by Mr. Wheeler in reference to antiseptics. The cases Mr. Wheeler had brought forward seemed to be tolerably well balanced both as to character and number, and his position was that the first class of cases dressed according to his own method as compared with the cases dressed according to the Listerian method resulted in favour of his plan, and utterly against the Listerian. In the Listerian cases the average temperature was a degree more than in the first class of cases. The cases brought forward might be an excellent testimony to Mr. Wheeler's skill and prowess as a surgeon, but he utterly denied their usefulness as a scientific test applied to a scientific method. The cases alleged to be treated by Listerism were altogether wanting in the exactness of detail necessary to form a judgment upon them as evidence. Why did he say he declined to accept those cases as proof against a scientific method? Simply because the results brought forward as the results of the Listerian method he believed to be impossible if the Listerian method had been properly practised. He had had an opportunity of visiting several hospitals, and of seeing Lister's method practised. On one occasion he remembered seeing a spray at full pressure, but there was no carbolic acid being pumped on the wound at all, nothing but a great volume of steam, which was simply urging into the wound all the germs that came within its scope. Again, he had seen other cases where a squirt of carbolic acid was being put upon the wound, and the surgeon, who happened to be near at hand, was invited to put his finger into the wound. That was surgical filth, the hand not having been purified by any immersion in carbolic lotion. Yet these cases he had heard described as carried out thoroughly according to the Listerian method. He did not impute that Mr. Wheeler had not carried out the cleanly method as he thought properly, but as a series of cases the results he got were impossible, and against the experience of surgeons who had practised Listerism in the proper way. A number of surgeons imitated Listerism with a certain degree of impartiality, but were at heart unconsciously prejudiced against it, disbelieving in the method, and being superior to the small details on which so much depended. Mr. Wheeler had mentioned several cases in which there were sinusses without giving the history as to how they were treated. In the list brought forward by him it was interesting to observe the way in which he described the results. One was described as "purulent," the next "very purulent," the next "suppuration," the next "free suppuration," and the next "profuse suppuration." He should like to ask Mr. Wheeler what was his theory of putrefaction? He had not said so in specific words, but as Mr. Thomson thought, he disbelieved in the germ theory. If he believed in the germ theory his method of treating the cases mentioned was utterly inefficient, and if he did not believe in it it was utterly unnecessary; because his position was this, that cleanliness, physiological rest, and drainage, were all the requirements needed to bring about the desired result. If cleanliness was all that was necessary, what did he use carbolic acid for? Pure distilled water was as clean as anything he could get, and last year he brought forward a case in which pure water applied to a stump had healed, while a case in which he used the Listerian method had taken two months to heal. Mr. Wheeler had made a point of the presence of germs in an abscess. Mr. Cheyne, who was assistant to Lister at King's College, had published a number of experiments with reference to the influence of the spray and the presence of germs in abscesses, and the result of his experience carried over a large number of cases was that, at all events, so far as chronic abscesses were concerned, there was no such thing as any organism existing in them. So far as acute abscesses were concerned, only a small proportion contained any organism, and these of a kind called micrococci, which had been proved by experiment on the lower animals to be innocuous. Injected into rabbits, and even into his own person, the micrococci did not produce inflammatory action, while in the case of true bacteria, the rabbits exhibited symptoms of blood poisoning and died. It was the micrococci that were found in abscesses, and not in open wounds. With regard to the effects of the spray, Mr. Watson, of New York had carried out a number of

experiments on its use and powers in preventing putrefaction, and the result of his experience in a great number of experiments, in which meat was put into a flask and allowed to putrefy, was that the meat which, before being put in, had been subjected to the action of the spray, did not become putrid for 25 or 27 days after that which had not been subjected to the action of the spray. Mr. Wheeler had made a point in reference to the German hospitals, and the filth of them, but he (Mr. Thomson) did not quite see the force of it; because if they were such pest houses as he described, and that now with the Listerian methods results were obtained in which pyæmia and septicæmia were practically excluded, the argument was strongly in favour not of general cleanliness at all, but of the special means taken to get rid of those unfortunate surroundings. It was not contended for a moment that Listerism was essential to the healing of wounds. No surgeon attempted to argue that proposition. But what he did contend for was that Listerism was the best method of antiseptics known, and gave the best results. If Listerism and Wheelerism were both stopped to-morrow wounds would still get well. But what was sought to be achieved by the Listerian method was a reduction of the death-rate from septicæmia and pyæmia, which, without its use, always amounted to a considerable percentage. Prof. Schede had collected statistics from a number of German hospitals in which antiseptics according to Lister were used, and comparing the result of a number of years' operations with the result obtained some years previously, when no Listerism was used, it appeared that out of 321 major operations, chiefly amputations and excisions treated antiseptically, there was but one death from septicæmia, while out of 327 cases in which Listerism was not used, and no form of antiseptic surgery in the common acceptance of the meaning, there were 91 deaths from pyæmia and blood-poisoning. Mr. Wheeler also took occasion to quote Sir J. Paget in reference to a point of statistics rather favourable to him, but he was not quite fair in his quotation. He (Mr. Thomson) would supply the omission. In the discussion that took place in St. Thomas's Hospital on antiseptics, Sir James Paget first spoke of the extraordinary results that followed the use of Listerism in the practice of ovariectomy, and he then went on:—"A few years ago I believed that I had never seen a patient recover after the opening of a lumbar or a psoas abscess with a free incision; I could not remember one who had not died before the opened abscess healed. Of late years, I have known such abscesses opened with complete immunity under antiseptic treatment, and there has seemed nothing but this treatment to account for the difference of the results." He thought it right as one practising antiseptic surgery according to Lister, and believing thoroughly in the principles on which it was based, that the statement in Mr. Wheeler's paper should not be allowed to go forward without some expression of dissent.

Dr. F. B. QUINLAN said everybody would be disposed to agree with Mr. Thomson that if Listerism was practised it should be practised in its entirety, and that a great number of the cases of alleged Listerism were not in reality according to Lister's method. Unless every detail was followed and every precaution used the weakest link in the chain would snap, and failure would result. He was disposed to agree with Mr. Wheeler in a great deal of what he brought forward. One inconvenience in the use of the spray had not been touched on at all, and that was that where patients were dressed in bed with it the steam wet them to such a degree that he had often seen colds and considerable injury supervene from the wet garments, and the steam condensing upon them. Rest, cleanliness, and drainage were known in the profession a long time. The drainage was recommended by Mr. George Calender, and carbolic acid was recommended by a French medical man, M. Lemaire. He had himself seen a case of Mr. Wheeler's, that of a little boy, on whom excision of the elbow had been performed, and treated with cleanliness, drainage, and rest. He never saw a case that went on more satisfactorily or had a better termination, the limb being capable of flexion, extension, and rotation.

Dr. HENRY KENNEDY said he was old enough to recollect long before Listerism or any other ism was in use, and it was then a common thing to see wounds running the same course they did now-a-days; for instance he had seen amputations of the thigh heal up without a particle of suppuration. On the other hand, he had seen erysipelas supervene, the stump slough, and other serious consequences. That was before Listerism or any other system except cleanliness was in use. In considering the question, it should always be recollected what might go on in the absence of the means advocated; for it

seemed to him that those casualties after amputation arose from the state of the patient's constitution. Again, in connection with that subject it should never be forgotten that every hospital surgeon must have seen that at times wounds would not heal at all, and at other times they would heal under disadvantageous circumstances. Therefore, the result might be attributed to causes other than whether the wound was dressed by cleanliness or by Listerism. Speaking as a reader, and more in favour of Listerism than of anything else, a number of cases of fearful compound fractures had been treated, especially in Glasgow, with exceedingly favourable results by modified Listerism. Those were cases in which twenty years ago amputation would have been performed, and yet by the use of carbolic acid they did very well without amputation. In the last volume of the Medico-Chirurgical Transactions was an important paper by Dr. Tait, of Birmingham, and it went a long way to shake one's confidence in Listerism by giving a number of cases of ovariectomy where cleanliness seemed to be exceedingly successful. Those cases were on record, and worth bearing in mind as showing the caution that should be exercised before arriving at any conclusion on this important subject.

Dr. T. STACE thought it was the bounden duty of everyone present to give expression to his feeling, as there was no chance of a division on the debate. He could not but consider that Mr. Wheeler's paper tended in a retrograde direction, and he was sorry there was no chance of comparing the statistics in it with those brought forward by Mr. Thomson, inasmuch as Mr. Wheeler's cases were remarkable in having no mortality whatever among them, whereas Mr. Thomson's showed a fair death-rate both from pyæmia and septicæmia. He denied *in toto* what he might call Mr. Wheeler's major premise—namely, that Listerism was carried out in the cases he had brought forward. Perhaps the limit of time prevented him from giving the proofs, but certainly several cases bore on their face the unmistakable stamp that Listerism was not carried out in them. He jotted down a case where the temperature rose to 105 deg.; and there was free suppuration, and a terrible smell when all the bandages were taken off the stump. It should not be forgotten that if Listerism was not carried out in its entirety a greater amount of damage might be done by bandaging too tightly. Again, as Mr. Thomson had indicated, they had no history of how the sinuses were treated, or whether they were disinfected before the wounds were bandaged up. One case of the lot falling to the ground he would let the rest go with it, so far as relying on the scientific accuracy of the way they were dealt with. Mr. Savory some time ago gave a great tirade against Listerism; but seeing his own cases it was no wonder. On a visit to St. Bartholomew's Hospital the steam spray apparatus was not working, and the hands of the surgeons were never dipped in any solution, yet Mr. Savory had tabulated the results as of cases in which Listerism was carried out. It was rather a mistake to talk so much about Lister in the matter, not that he did not think that to his genius was to be attributed all the attention shown to antiseptic surgery, but if some term, like "antisepticism," was applied, that would not excite jealousy or animosity at the name of a private individual, it would be more fortunate for the system. In his earlier experiments Mr. Lister had to go step by step, and he found out many errors which were still perpetuated by surgeons who ought to know better with his experience to guide them. They had instances of the sealing up of sinuses not purified at the time of the operation. He had listened with pleasure to the speech of Mr. FitzGibbon, who was evidently an antiseptic surgeon, and had taken great pains in working out the system. Besides his mode, he might suggest ordinary sheet gutta percha as an envelope for confining the dressing. Drawing conclusions from the use of carbolic spray Mr. Wheeler said it militated against the idea of Listerism, when the strength of the spray decreased along with it, decreased the suffering from the operation and the ill results. The whole explanation of that was that there was no more irritating thing in the world than strong carbolic acid, or perhaps no more dangerous thing to apply to a large wound. On one occasion he saw a patient poisoned by the application of carbolic acid to a large wound. He did not think Lister would now-a-days advocate carbolic acid in any shape next the wound. Mr. FitzGibbon referring to mortification in the flap carefully drew the distinction between mortification and putrefaction. Though the body was there dead, there was no smell from it or irritation, because there was no putrefaction. Perhaps nowhere in the field of surgery was there a

better opportunity of studying the value of an antiseptic agent than the root of a tooth; because the surgeon there had command over the whole thing—he could seal it and cork it up without the chance of an external agent getting at it. But until antiseptic treatment came to be used it was unknown to be able to seal up altogether a tooth in which the nerve was dead, i.e., a tooth in the root of which was a mortified nerve, or putrefaction would set up and all the serious train of symptoms that followed. By antiseptic agency that baneful influence was now counteracted, the mortified nerve reduced to a state of harmlessness, and the dental surgeon and his patient gave thanks to the genius that brought to the front antiseptic principles.

Dr. PUREFOY said Mr. Keith, who had had such extraordinary success, had further increased it by adding Listerism to his plan of dressing. Hitherto his successes reached 85 per cent. However, a recent number of the *New York Obstetric Journal* states his successes reached 90 per cent. since he adopted Lister's plan of dressing in his operations.

Mr. WHEELER said, in reply to Mr. Stoker, that if every one was to stick to their own opinion, in spite of what any one else said, why did he ever change to what he termed "Listerism?" It was necessary to make a distinction between the term "antiseptic surgery" and "Listerism." By the former, as explained in his paper, he meant adequate drainage, cleanliness, and rest, as brought forward by Callender and Heath. By the latter, as called by Hutchinson and others, he meant the spray and the gauze. Now, Lister had nothing to do with drainage; and it should be borne in mind that Heath and Callender had introduced it, and also that it was Lemaire who had introduced carbolic acid, while physiological rest was due to Hilton. Therefore, it was upon the depriving the air of its impurities by the spray that the theory of Lister was founded. Mr. Stoker had thought it very suspicious that he (Mr. Wheeler) argued that Listerism produced worse results than any other system, and that he had before heard of its producing merely equal results, but never worse. In the *British Medical Journal*, Dr. Bantock announced that he had had better results since he gave up Listerism; and similar testimony was given by Savage, Lawson Tait, Tredeleburg, and others, not to mention the opinions of Hutchinson and Bryant. In fact, Jonathan Hutchinson stated plainly that Listerism was not suited to compound fractures, or to wounds where inflammatory action had already set in. Again, Volkman stated that the spray produced an affection which he termed aseptic fever; and Bantock stated he had lost ovarian cases from the same cause. He had not the slightest objection to Mr. Stoker's denominating the cleanliness he practised and advocated as "Wheelerism;" and he could only say that if Mr. Stoker practised cleanliness, drainage, and physiological rest, he was quite certain he would get equally successful results. Next dealing with the remarks of Mr. Fitzgibbon, it was a mistake to say that he (Mr. Wheeler) used carbolic acid of indefinite strength, as he was particular to use it of strengths 1 in 20 and 1 in 40; and in many instances he had used not carbolic acid at all, but chloride of zinc—sometimes 10 and sometimes 20 grains to the ounce, as specified in the margin of his communication. He never attributed gangrene to the spray or the gauze, and had merely alluded to gangrene because Nussbaum had boasted that since he commenced Listerism he never had an operation followed by gangrene. If that were a matter to boast of, he (Mr. Wheeler) never, in the whole course of his practice, had such a calamity at all. With regard to exposure of the surface to the spray, they had the records of Bantock and Lawson Tait, of Thornton and Savage (the latter being ardent Listerites), as to septicæmia, suppression of urine and aseptic fever supervening. Mr. Fitzgibbon had expressed his opinion that, when carbolised gauze excited eczema, it was badly made, lacking sufficient oil. But that could not be so, as carbolic oil had produced similar irritation in some of his (Mr. Wheeler's) cases. Mr. Fitzgibbon had stated that some of his (Mr. Wheeler's) cases "smelled;" but that even cases of gangrene, when dressed according to Listerism, did not smell at all. That was not in accordance with the fact, as there were members of the Society present who could testify that the case of a rectangular flap operation which he had referred to, although dressed with all the elaboration of Listerism, became gangrenous, and was most offensive to the sense of smell. Perchance, one or two of his cases did smell; but, as he maintained, the same might occur in cases treated by Lister's method. Dr. Kidd and Dr. Barton had seen many of his cases, and were unable to perceive any unpleasantness about them. At present, he had under his

charge in hospital an excision of the knee, a Syme's amputation of the foot, an excision of the breast, a hare-lip, and a case of large epithelioma, removed all in the female ward, and he would be glad, if any gentleman who desired, would see those cases in the early morning, and judge for himself whether or not there was any unpleasantness about them. Dr. Barton coincided with Mr. Thomas Smith, that the spray often did not suit children; the cure of the sinuses, as he stated, was rather *post hoc* than *propter hoc*. Mr. Thomson had stated that the mean temperatures in the Listerian cases were a point higher than in his (Mr. Wheeler's) cases treated antiseptically. There was nothing extraordinary in that, as it would appear from the journals, that according as the strength of the spray was reduced, making it compatible with Listerism, the temperature proportionately reduced, and in ovariectomy after Listerism, the temperature of 107° had been recorded.

Mr. THOMSON said what he meant to convey was that the result, as regarded temperature, was impossible in cases properly Listerised.

Mr. WHEELER continued that he was about to deal with that point where Mr. Thomson had denied the usefulness of the cases as a scientific test. It was begging the question to say he had not carried out Listerism correctly; because if some of the cases quoted produced results such as would satisfy Listerites there was no reason to assume that Lister's method had been departed from in the others. It was also alleged that no history of the treatment of the sinuses had been given, although fully described that they were scraped, washed, and brought together by catgut suture. It was quite possible he had had less suppuration in the nineteen cases than in the thirteen; but the numerical difference would account for that. "Why did he use carbolic acid?" That question was asked in the discussion on the subject last session, and it was asserted that if Mr. Spence used carbolic acid at all he admitted the whole theory of Lister. The reason he used carbolic acid was this, not as a germicide, but that it was easier got than distilled water, which he would just as soon use, and he used chloride of zinc and salicylic acid for the same reason. With regard to germs within the body, he was aware of what Mr. Cheyne had said; but he was the same gentleman who had put forward the statement based upon three cases, that loose cartilages might now be removed by direct incision from the joint without fear of evil results, and he had italicised the word "*now*." Mr. Thomson was wrong in his view as to micrococci, if Nagele and others were to be believed that in these abscesses were found the chain bacteria. Dr. Bantock's results with fluids, mentioned in his communication, refuted those ascribed to Mr. Watson. However, it was sufficient with regard to the germ theory, that germs were found in the secretions which had been treated by Listerism, just the same as in wounds treated simply by cold water. Thomson objected to his saying that Nussbaum's statistics were receivable because he had introduced a system into an hospital which had been a terrible pest-house. However, read Lister's answer to that in M'Cormack's book on the subject, and it comprised nearly all that Mr. Thomson had said?

Mr. THOMSON denied having read Lister's speech, though Mr. Wheeler seemed to imply he had spied his argument.

Mr. WHEELER said Mr. Thomson had adopted from the book containing Mr. Lister's speech; but he could only explain the similarity by supposing it was a kind of animal magnetism that pervaded Mr. Thomson; he was such a thorough believer in Lister. So with regard to the pest-house, introduce Listerism, or the spray and the gauze, and the hospital must be greatly improved, the same as from any other forms of cleanliness. Sir James Paget went further than he did, and stated there were several reasons why they had such good results at present; first, the bad practices of the surgeons had been given up; secondly, there was a great deal due to Sir James Simpson for improved ventilation; thirdly, to improved nursing; fourthly, increased education; and he went further, and said there was now a rivalry among surgeons as to who would produce the best statistics. Again, having a perinæum and a split in it, it healed up, though the mucous channels were said to be filled with bacteria, that would cause suppuration and prevent union. In a speech at Richmond Hospital, Mr. Lister said: "Now, that healing without the formation of pus implied that the lymph did not putrefy, for if it had done so the putrefaction would have involved suppuration. But if the lymph had been put between two bits of glass or gutta-percha paper at the same temperature it would have putrefied. What was the

reason of the difference? Somehow there is a peculiarity in living tissue as distinguished from ordinary matter that acts antiseptically—as we may say, prevents the development of septic organism." And, further on, Lister says:—"that healthy living tissue has the power of counteracting the development of septic organism." These were Lister's words, written by Mr. Thomson, that the living tissue had got the power of acting antiseptically. In addition to this—and they knew it as a fact—that with proper and adequate drainage a fluid resulted of that density in which bacteria could live. But that recalled Dr. Kennedy's argument as to the *vis viva*. Living tissue acted antiseptically. Well's experience was that his mortality had decreased as his experience increased; and since adopting Lister's method his mortality was exactly the same as two years before he took any antiseptic precautions. That was Spencer Well's own statement in the *British Medical Journal*. That journal never went wrong, and so he found in the issue of the 29th ult. what he should designate as a hedging article, viz:—"That the spray is not by any means absolutely essential for antiseptic work, and that a septic result may be obtained without its use is at once evident from the experience of Lister himself." Thus the same results could be got without the spray as with it. Trendelenburg had given up the spray and adopted the practice of irrigating the wounds. There was the *British Medical Journal*! Mr. Stack said he had not had mortality in his cases, forgetting at the onset he had so stated. Of course he had, like every other surgeon, cases of mortality. The last case he had of ovariectomy died, and he had two sprays working. Now that his mind was opened, he believed she died of aseptic fever; that she was killed with the carbolic acid spray. Though he had not brought forward his statistics, he ventured to say without wishing to be egotistical, his cases would bear comparison with those of any other surgeon. With regard to the temperature, Mr. Stack took it down rightly as 105 degrees in the case mentioned, and he said had Listerism been carried out rigidly, that could not happen. The temperature was 105 deg., pulse 140, and he removed the carbolic dressings; she had partial suppression of urine and black urine: and she was at present alive at Ballybay. He never said there was a terrible smell.

Mr. STACK begged to say that what he said was that the case on the face of it could not have been treated by the antiseptic method, and the explanation showed it more emphatically still.

Mr. WHEELER said if using spray of 1 in 20, and lotion of 1 in 40, and putting the knives into the carbolic acid and washing his hands in it comprised Lister's method, he had adopted Listerism. But it was not clearly understood what Listerism really was. He remembered Dr. Lawson Tait pulling up Mr. Thornton on that point; and he would take leave to take issue with Mr. Stack for stating that Lister would not advocate carbolic acid in any shape next a wound. For himself he had not the slightest animosity to Lister. On the contrary, he had a high respect for him. He had met him once, and Lister had been exceedingly courteous. As to the tooth, he might observe that there were no antiseptics used in stuffing one of his, and for the last eight years he had no pain from it whatever. With regard to Mr. Purefoy's remarks, there was no doubt Keith had wonderful success. But was it the fact that in his early ovarian cases there was not any preparation of the patient beyond a purgative? Did not that prove that his more recent successes were due to his skill derived from experience. In conclusion, he would allude to Galezowski, who has justly been described as raising a laugh at the entire system for his remarkable successes with the use of a solution of carbolic acid of 1 in 1,000.

Mr. THOMSON said he would like to read the balance of one of Mr. Wheeler's quotations from Spencer Wells, viz:—"Since adopting the antiseptic method in 1878 he had 131 cases, with 13 deaths, or 10 per cent., the death-rate being exactly the same as in the last two years of hospital practice without special antiseptic measures. Before he used antiseptics the results of the intra-peritoneal method had been less favourable than those of the extra-peritoneal. The reverse was now the case. He had never seen a remarkable rise of temperature after antiseptic ovariectomy—it rarely rose above 100 deg."

Mr. WHEELER said he had read that quotation.

Mr. THOMSON said he had not read it.

Mr. WHEELER thought he had; but, at all events he had

nothing to do with Mr. Spencer Wells' temperatures, and had not alluded to them in his paper.

The Society then adjourned.

## Special.

### THE "SYSTEM" OF UNIFICATION AND THE ARMY MEDICAL DEPARTMENT.

AMONG the many changes of late years introduced in the several branches of the Army, none has been more generally opposed and condemned by officers practically acquainted with the subject than that by which, under the name of "Unification" the medical department has been thrown back to a condition out of which, early in the present century, it had been emancipated.

The circumstances from which this retrogressive movement appears to have sprung, date from 1854-6; that is, from the Crimean War. In the long interval of exemption from war against an European enemy, which had preceded that period, false economy on one hand and partisanship on the other, had so successfully combined to reduce the working power of the medical department, alike in *personnel* and *matériel*, that on war suddenly taking place, such hospital establishments as could be hastily thrown together were, very naturally, found to be unworkable, such as belonged to regiments absolutely insufficient for purposes of field service. Unfortunate as these circumstances were in themselves, they were not of necessity beyond remedy, had the directing head of the department the particular kind of knowledge that would have been useful in the emergency—that is, actual experience of war. But this was precisely that in which he was deficient. Had reference at the time been made to the autobiography of his predecessor in office, the steps might have been traced by which some forty years before, the department, by means of the "double" system, staff and regimental, had been rescued and brought into working order out of chaos such as then characterised it. Unfortunately no such reference to the history of the past appears to have taken place, at any rate to have been profited by, and so those who from whatever cause sought for an indictment against any medical administration found one, ready made as it were to hand. Destruction, not renovation and improvement, was thereupon determined, and how persistently and well the process has continued to be conducted ever since can be attested by the great majority of classes who have been affected thereby.

The general idea in accordance with which the scheme of unification now in force appears to have been set on foot, has its pattern partly in the establishment of a civil hospital such as any of those to be found in our large cities, for the general population, partly upon the model of the ambulance system of the French army, forgetful that the former in their nature "sedentary" are thereby unsuited to the purposes of our army in motion, and that the latter have for years been condemned by the *service de santé* almost without exception, that in them, to use the very words applied, "the requirements of the sick are sacrificed to administration." No doubt in the service of this country all the medical officers concerned in conducting the details of what, properly speaking, can hardly be designated a *system*, do their best to reduce to a minimum the disadvantages and evils to the service generally that it involves. But there are some inherent in itself which no exertion, no sacrifice on their part can do away with. Among these are the frequent changes that occur in the medical officers who have to treat individual sick, whether soldiers, officers, or members of their respective families; the want of acquaintance with

their several conditions and requirements such as can only be obtained by continuous acquaintance and association with these classes; and that relatively imperfect hygienic superintendence which is inseparable from existing conditions. Fortunately the system of regimental hospitals and of regimental medical establishments has not yet been wholly abolished in India.

#### ARMY, NAVY, AND INDIAN MEDICAL ITEMS.

We regret to learn that Surgeon-General Sir A. D. Home, V.C., K.C.B., at Madras is indisposed. He received a chill when visiting Ootacamund, and an attack of bronchitis has been the result.

The new Royal Warrant for the Indian Medical Service sanctions twenty-one brigade surgeons for Bengal, fourteen for Madras, and nine for Bombay. These promotions are to be made by selection from amongst the list of surgeons-major, with effect from November 27, 1880. Under the operation of this Warrant it is said that the appointment of brigade surgeon of the Hyderabad contingent is about to be created.

We understand that the abolition in India of regimental hospitals is steadily, if not very rapidly, progressing. In that country practical working of these establishments to the great benefit and advantage of sick soldiers has, more than in the United Kingdom, stood in the way of theoretical schemes. The history of previous attempts in the same direction, and of their failures admits of ready reference in the pages of official records. Hence, no doubt, much of the opposition shown against the contemplated innovation—an innovation, the object of which, if attained, will restore a state of things which had to be done away with even before this century began.

ACCORDING to the daily papers there exists a need for additional medical *matériel* to meet the requirements of the sick and wounded of the British troops operating against the Transvaal. If, as stated at the time, a chief object in reverting to a system of base and field hospitals in place of regimental and general, as heretofore, was thereby to avert all such shortcomings, the endeavour has yet to prove its success in this as in every other respect.

THE Secretary of State for War has issued very liberal orders with regard to the wives and children of the soldiers who have proceeded from India to South Africa. If they desire to be sent to their homes they are to be so; those who have no homes to return to, or do not wish to return, are to be accommodated in barracks; special allowances are, moreover, to be granted to them, at the rate of ninepence per day to the wife of a non-commissioned officer, sevenpence to the wife of a private soldier, and fourpence to each child.

AMONG the officers upon whom honorary distinctions have been conferred, the following of the Army and Indian Medical Services have been gazetted companions of the Bath in recognition of their services in Afghanistan, namely, Deputy Surgeons-General De Renzy, Townshend, and Hasard, and Brigade-Surgeon Hanbury. But in the list of honours no mention appears of the medical officer with whom rested the general organisation of the entire department on the same occasion.

We regret to observe that among the officers dead by wounds received in the late fight with the Boers are Surgeon-Major Cornish and Surgeon Landon.

THE Duke of Connaught has consented to preside at the anniversary festival of the Hospital for Sick Children, Great Ormond Street, London, to be held at Willis's Room on Wednesday, March 16th.

DR. A. WHYTE BARCLAY, Physician to St. George's Hospital, is the newly-elected President of the Royal Medico-Chirurgical Society.

DR. J. MATHEWS DUNCAN, the new President of the Obstetrical Society of London, delivered a very able inaugural address on Wednesday last.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, MARCH 9, 1881.

#### POLITICAL MIDWIFERY.

DR. MATHEWS DUNCAN'S presidential address to the members of the Obstetrical Society of London is, in many ways, an important contribution to the history of midwifery. In some respects it is less characteristic of the distinguished physician than are the lectures and essays by which he is so familiarly known; it is deficient in the peculiarities of expression that we have come to associate with Dr. Matthews Duncan's work; but it is, notwithstanding a most emphatic and forcible call to obstetricians to hold to, and urge yet further ahead, the advance that has been witnessed in their field of labour within the time the Obstetrical Society has prosecuted its good work. The address is, perhaps, the best incentive to progress that could have been offered; it is better than a simple review of the improvement a year has seen; the latter would have been useful as affording information and recalling triumphs, but the actual address itself is infinitely more serviceable; it clearly exposes what is wanting to be done, and at the same time gives due credit for what has been accomplished, in the direction of much needed political reforms. A great society, strictly medical though it be, has great duties to discharge. The recognition of these is a first necessity of its being, as the vigorous effort to accomplish them is a primary essential to its continued existence. It is good to know, therefore, that the Obstetrical Society is alive to its own importance; that it respects the demands rightfully made upon it; and that it is eager to fulfil its legitimate functions as may most advantageously serve the cause of progress. That this happy condition of affairs will continue so long as men of Dr. Duncan's

calibre and practicability occupy the chief post on its Councils, we can rest contentedly assured. The example of their own achievements, and the infection of their own earnestness, will alike tend to gather round them the best spirits of the age in which they live.

The instruction of women in the art of midwifery is a subject to which the Obstetrical Society has devoted considerable attention. The necessity for an improvement in the condition of those who, merely as a means of living, undertake the duties of an accoucheur, apparent, as it is, to every trained physician, could not fail to influence a special association of obstetricians; and in 1872 the Society proposed a scheme of examination, and offered certificates of proficiency for such candidates as underwent the test with credit. In eight years seventy-one candidates have received diplomas of proficiency, a number that is but a fraction of those who make up the class of midwives. It is reasonable to insist that the responsibilities attaching to the delivery of a parturient woman, are of a nature to require that the attendant shall at least be acquainted with the accidents and complications that may accompany labour; that the dangers and difficulties to be apprehended shall be plainly understood; and that assurance may be felt of the fitness of the midwife for the duties she is essaying to perform. It no doubt is a fact, that midwives are, as a rule, competent to discharge the task of delivery under normal circumstances; but that the majority of them are able to appreciate, and to interpret, the signs of imminent disaster, we do not for a moment imagine. In a matter of so much importance, therefore, a matter in which the safety of innumerable mothers and children is concerned, it is imperatively necessary to secure absolute legislative control over the preparation and practice of those who seek to enter the ranks of midwives. In the absence of a state department of medicine in this country, there is no body so fit to undertake this supervision as the Obstetrical Society. It should be the natural guardians of all pertaining to midwifery; and in the matter of instructing and licensing midwives, there can be no question raised as to its especial qualifications. It is to its honour that the voluntary effort in this direction has been already made; and it is to the general welfare of the country that it should receive complete authorisation to conduct the examination of midwives, with power to punish such as practised midwifery without the protection conferred by its diploma. It would be interesting to know the average success accompanying the practice of unqualified accoucheurs. The information ought not to be difficult to obtain; it would involve a considerable amount of inquiry, and some little ingenuity, on the part of those making it; it would, however, well repay the trouble of acquiring it, by the instructiveness of its details. We might anticipate that little difficulty is encountered usually in cases of normal labour; but in those instances where the regular course of Nature is not observed, and where the resources of the midwife are alone relied on to overcome the obstacles presented, there is no doubt that frequent and often preventible fatality ensues, either to mother or child, or to both. The reports of coroners' inquests, the accounts given by pregnant women of their former confinements under the care of midwives, are all of them aids in determining the extent to which unskilled

assistance is blameable with labour accidents. The magnitude of the mischief done is not appreciated, because it is not perceived at a single glance. The instances of mishap are never at any one time so numerous as to command universal attention; but were they once collected together—were, for instance, every death due to incompetency of midwives which has taken place within the past twelve months, fairly brought before the notice of the world, there would be an immediate and irresistible demand for Government interference to prevent the recurrence of such slaughter in the future. The aim of those who seek to bring about this desirable consummation should be directed to making the public acquainted with the extent of the evil being wrought in its midst; and the Council of the Obstetrical Society would be wise if it initiated an inquiry to this end. That there is unanimity of opinion among the members constituting it, on the point, there seems no reasonable doubt; there is wanting only some sufficiently determined effort to commence the inquiry, and towards this Dr. Matthews Duncan has contributed at least one man's share. So long as qualification is optional for midwives, only a very few of them will undergo the instruction necessary to give them an intelligent grasp of the elements of obstetrical knowledge. Their ranks are recruited at present from the decidedly inferior classes; most of those with whom we have been brought into contact, are but little removed from the glib, illiterate type, exemplified by the Mrs. Gamp of Dickens' experiences. These women are at the best but indifferent assistants; they never rise to the level of responsible principals; and it cannot but be a matter for serious concern that no inconsiderable number of the births that annually take place in Great Britain, are mainly superintended by them. As a question of national importance, the matter is one calling for prompt and definite settlement; a discussion of the means by which the end sought may be attained must, by right, be conducted on the bases suggested by the President of the Obstetrical Society; and to that body may safely be relegated the task of suggesting a scheme for the adequate fulfilment of the conditions to be demanded. It has already shown that the question is one of deep interest to it; it has even gone further, and volunteered such amendment of the existing evil as could be possible by its unaided powers. The attempt has been in a measure successful; it now remains for it to be encouraged in its endeavours, and to be fortified further by the Government, and in such wise that none without the stamp of approval conferred by its license, or, at any rate, an equivalent mark of competency, shall in the future be permitted to practice what is, when all is said, in its essence a branch of medicine.

There is undoubtedly in England a comparatively less frequent resort to the services of non-medical accoucheurs than is the case abroad; but even with this reservation, the number of persons who, either from prejudice or sentiment, refuse all but female assistance during labour, is, in the aggregate, a large one. Indeed, we incline to think that it is a very appreciable proportion of the whole, and that in towns as commonly as in country districts the midwife is called to render aid. This consideration, however, can only modify the terms of an arrangement, it cannot affect the prime question, which

is, that so long as midwives pursue their calling it is attended with vast risks while measures are wanting to ensure that they are not ignorant of the outlines of their duties. In outlying thinly-inhabited regions the midwife has a proper *locus standi*; far removed it may be from the situation in which the regular practitioner can make a fair living, she is valuable when at hand to respond to the call made on her services. Her occupation will admit of her depending on her special vocation only in part, and hence her time has not the value apportioned to that of a hard-worked country doctor. A trained midwife, under these circumstances, can see a normal case successfully through; and her education, moreover, will enable her to judge whether sequelæ to delivery present any feature that would make it necessary to invoke full medical assistance. When, on the other hand, unusual or dangerous symptoms presented, either during or successive to, actual labour, the midwife, being taught to perceive them and to recognise their importance, would immediately send for the nearest resident physician; and pending his arrival her efforts would be intelligently directed to supporting the patient under the adverse circumstances. Thus taught to co operate with and depend on medical men, qualified midwives would be an invaluable addition to the extra-professional resources of medicine; and they, on their part, feeling that they hold a well and universally recognised position, would be anxious at all times to deserve the confidence reposed in them. When this condition of affairs has been brought about, that body, be it the Obstetrical or any other society, to whose energies it is due, will deserve and receive the united thanks of the professional and lay public alike.

There are several points raised in Dr. Matthews Duncan's address on which profitable comment might be expended, we have, however, dwelt somewhat lengthily on what is perhaps the most important of all, and of its importance, there will be but one opinion.

#### THE TRICHINOSIS CRAZE.

We learn from *L'Union Médicale* that within the space of eight days, there has been a complete change of opinion within the Academy of Medicine, Paris, as to trichinosis and trichinæ. The panic into which the learned society was thrown by M. Laboulbène's announcement is, by this time, known to all. All the speakers joined the league against the invading plague. Some spoke of nothing less than that an army of veterinary inspectors, armed with microscopes, should be sent to the frontiers, both seaward and landward, to spy out the invisible enemy, and on discovery, to drive him far from our soil. Others proposed to employ fire or water, roasting or boiling, as a means of destroying such trichinæ as might perchance elude the official microscope. Others, more radical, considering these measures inefficacious as a means of combatting the evil and guaranteeing the public health, demanded loudly that the importation of American pork should be strictly prohibited. The Academy dissolved without coming to a decision, referring further consideration to the next meeting, but leaving the minds of all present seriously occupied with the important question which the Academy had been called upon to solve.

The eight days which elapsed bore fruit. At the next meeting the minds of all were calmer, and the subject in question was approached with greater coolness. The Academy heard, with much interest, three communications on this subject; two drawn up by members of the Academy, who are well qualified to give an authoritative opinion, M. Colin, of Alfort, and M. Davaine: a third by a savant who is not, however, a member of the Academy, Dr. Vallin, of Val-de-Grace, secretary "du Comité consultatif d'hygiène," who has made a special study of trichinosis and trichinæ. These three communications, drawn up in the leisure and quiet of the study, must have, and have had the happy effect of calming the fears that had been entertained by the members of the Academy during the oral discussion which succeeded M. Laboulbène's communication. In his paper on this subject, a paper based on numerous experiments, conceived and executed with that scientific precision and practical good sense which distinguish most of the researches conducted by the learned professor of physiology at the Medical School of Alfort, M. Colin has demonstrated that, contrary to the opinion maintained by many, if the pickle be well made, and the cooking properly conducted, nothing further is requisite for the destruction of the trichinæ, and consequently, for rendering harmless meat infected by the presence of this helminth.

All that is requisite is, that the salt and the fire should be allowed sufficient time to effect their task of distribution; two or three months for salting, and from an hour and half to three hours for cooking, according to the size of the piece of infected pork.

M. Davaine, whose competence to pronounce with authority on this question is known to all, is even more explicit and reassuring than M. Colin. He asserted that he had not participated, at the previous meeting of the Academy, in the panic which seized so many members as to trichinosis; and declared that the process of cooking pork still employed, in France is in itself sufficient to destroy the trichinæ and to preserve the consumers of pork from trichinosis. Lastly, he demanded, not without a trace of sarcasm, how many cases of trichinosis had been observed in France since the disease had been first spoken of, exclusive of the famous Crespy-en-Valois epidemic, to which one person fell a victim.

M. Davaine might have added, that the young girl of Crespy-en-Valois, who, according to M. Laboulbène, fell a victim to trichinosis, died of typhoid fever; such at least is the opinion of M. Bouillaud, whose authority is unquestionable.

As M. Davaine proceeded with the reading of his paper, the brows of the members seemed to clear, their faces to become more serene. In language, in which humour was combined with scientific rigour, the honourable academician declared that there was more danger while walking through the streets of Paris, of a chimney falling on one's head, than of contracting trichinosis by eating pork of French origin. As to American-cured hams, cooking them in the French manner, destroys the trichinæ, if present, and thus renders harmless infected hams. It is quite unnecessary, therefore, to form a corps of inspectors, and send them, armed with microscopes, to

repel the invasion of so benign and so little to be dreaded a foe.

It is to be regretted, however, that there has been so serious a disturbance of the custom of eating pork among the poorer classes in France, and of the pork trade.

The question of trichinæ and trichinosis appears then to have been solved, and a decision given, contrary to that expressed by the pessimists in the previous meeting of the Academy. The absurd part of the affair is, that this favourable, if not optimist opinion, is pronounced immediately after a ministerial decree, which adopts the opinions of the pessimists, has been promulgated, absolutely prohibiting the importation of American pork. Almost at the moment when a member of the Academy, one of those whose opinion carries most weight, declares the American-cured pork to be innocuous, a decree is promulgated interdicting it.

### THE RESIDENCY OF THE CARLOW DISTRICT ASYLUM.

In our issue of November 10, 1880, we drew attention, as our readers may recollect, to the appointment that had recently been made of Resident Medical Superintendent at Carlow Asylum. We had no intention of entering again upon this question, but we feel bound to notice the very contradictory and unfortunate statement made by the Chief Secretary a few nights ago in reply to a question from Colonel Tottenham on the subject of the Carlow appointment.

Colonel Tottenham asked under what circumstances the claims of the assistant resident medical superintendents of the Irish lunatic asylums were overlooked in the recent appointment of resident medical superintendent of the Carlow Asylum, and whether the gentleman who received the appointment had any special qualifications justifying this supersession, or had ever served as an assistant in any lunatic asylum?

To this Mr. Forster said it was not the case that the claims of any of the applicants for the appointment of resident medical superintendents to Carlow Lunatic Asylum had been overlooked. They all received careful consideration. The gentleman selected was already intimately acquainted with the asylum from the fact of his having attended there during the official visits of his father, the late visiting physician to the asylum, and having on several occasions discharged the duties of the late resident medical superintendent while he was absent on leave. The question seemed to imply that some gentlemen had been superseded by the appointment, but that was not a fact. The assistant resident medical superintendents have no claims to the appointment. They are made by the board of governors, and their claims are considered with those of other candidates.

Colonel Tottenham said the right hon. gentleman had not answered that portion of his question, whether the gentleman appointed had ever served as an assistant.

The Chief Secretary said he thought he stated that he had been there during the official visits of his father.

The Chief Secretary here plainly stated that the assistant resident medical superintendents in the Irish asylums have no claim upon the Government for promotion because they have been appointed by the Boards of Governors. Now, supposing it to be admitted that work done in the service gives no claim for preferment, and that the Government are perfectly free to treat the un-

covenanted assistants as they please, yet the very terms of the advertisement in which the vacancy was notified, pledged the Government to take into consideration "peculiar qualifications for the appointment," and this gave the assistants a strong claim, since no one will deny that they possess such "peculiar qualifications" in an eminent degree. Mr. Forster was clearly troubled by a feeling that to overlook the assistants was a step requiring defence, and he therefore explained that the gentleman appointed to Carlow Asylum was the son of the late visiting physician, and, further, that he had on several occasions discharged the duties of the late resident medical superintendent while the latter officer was absent on leave. We agree with Mr. Forster in thinking that these facts count in favour of the Government choice, but it occurs to us that Mr. Forster is not aware that the visiting physicians (a deserving body of men for whom this journal has always stood up) are appointed by the Boards of Governors, as the assistants are; and we think Mr. Forster must have forgotten that the routine duty of the assistants is to act for the superintendents in their absence. Thus, the whole answer is perfectly contradictory. If the assistants had no special claim, neither had this gentleman, who was only a perfunctory assistant, while, if he had a special claim, then by Mr. Forster's own reasoning the assistants' right to promotion on the ground of fitness stands acknowledged *a fortiori*.

But we suppose it is unnecessary for us to tell Mr. Forster that the candidate who ought to be selected is he who has had most experience of the duties and who has shown himself most fitted to discharge them. This, therefore, is a sufficient answer to "a Poor-law Physician," who writes to the *Freeman's Journal* that, in his opinion, the assistant residents "can advance no professional claim, or point to any work done, which could in any wise distinguish them from the most obscure dispensary officer from one end of the island to the other—a pronouncement which relieves us from the necessity of discussing the writer's argument, raised upon so nonsensical a premise, for it might as well be said that every general practitioner is as fit to be an army surgeon as he who has served his time in a regimental hospital or at Netley.

The real truth of the Carlow appointment is that it was a political job, perpetrated to please an influential representative and, as the Chief Secretary should say something in defence, he made the best of it.

It would, we suppose, be chimerical to hope that ministers will offend political supporters by preferring special merit to hustings services; but, at least, we may expect that—if jobs must be done—the government will not raise false hopes by advertising for "peculiar qualifications," and that, when the job is done, an attempt will not be made to cover the ministerial retreat by repudiating the principle of promotion within the department, and disclaiming any obligation to appoint the man who knows his business best.

We altogether repudiate any intention to say a word against the character or attainments of the successful candidate. We simply observe that his knowledge of lunacy administration appears to have been much less than that of the candidates who had served as assistants in asylums, and, *pro tanto*, he was not the best man who might have been selected.

## ABSENTIA FELLOWSHIPS.

THE disreputable traffic in purchaseable degrees carried on for so many years by the Edinburgh Colleges of Physicians and Surgeons has received its first *coup* in the House of Commons last week, where

Sir Trevor Lawrence asked Mr. Mundella if he was aware that the highest qualification of the Royal College of Surgeons, Edinburgh—viz., the Fellowship—is to be had without examination, and even *in absentia*, by persons holding lower qualifications, on payment and by a process of vote by ballot; if he was aware that the highest qualification of the other two Scottish medical corporations—viz., the Royal College of Physicians, Edinburgh, and the Faculty of Physicians and Surgeons, Glasgow—is given on similar terms; and if he could inform the House whether such a system has ever been the subject of representation or remonstrance by the General Medical Council.

To this the Vice-President of the Privy Council replied—I have reason to believe that with regard to the Royal College of Surgeons of Edinburgh, a Fellowship can be obtained by persons who are already members of the Colleges of Surgeons in England, Scotland, or Ireland, upon the terms stated; but I understand that Fellowship is not a licence or qualification for practice, but is a distinction conferred by the College by a three-fourths vote. With regard to the Faculty of Physicians and Surgeons of Glasgow and the Royal College of Physicians, Edinburgh, I have not yet been able to obtain certain information. With respect to the question of so-called higher titles, I understand it was discussed by the Medical Council in 1859, and it was then decided that in the opinion of the Council, in future no licence or degree should be given by any of these bodies without examination; and in the year 1870 the subject was again brought forward in reference to Clause 16 of the Medical Act Amendment Bill, but in consequence of the withdrawal of the Bill, and pending further legislation, the subject has not been at present renewed. The question of these higher titles will form part of the inquiry into the working of the Medical Acts which the Government propose to shortly institute.

As to the fact of the F.R.C.S. Edin. being a registrable qualification and a complete legal title to practise, it is difficult to understand how the Vice-President of the Council could have been led to make to the House of Commons a statement which was totally incorrect, and capable of immediate disproof. This Fellowship is readily buyable by anyone who holds a diploma from any College of Surgeons, or even from the Glasgow Faculty of Physicians. It costs £25, involves no examination, nor any evidence of special study, and can be procured by a practitioner in any part of the world (even though he never heard of Edinburgh) if he can get a couple of Fellows (who have themselves bought the privilege) to say he is respectable. A vote by ballot *pro forma* of three-fourths of the assembled Fellows is necessary, and, we are told, is almost never refused.

In witness whereof, it is only necessary for us to state that a well-known colonial practitioner, who was tried some years ago for having caused the death of a patient in an attempt to procure abortion, and who has recently been obliged to confess in the witness-box that all his published works were written by other people, and that his credentials were obtained by bribery, purchased the F.R.C.S. Edin., and his respectability being duly vouched by two Fellows, and was co-opted by the ballot vote, now holds the distinction (?)

Mr. Mundella's excuse for the sale and barter of this

Fellowship—viz., that it is not a legal licence to practise—is altogether devoid of foundation. The F.R.C.S. Edin. is one of the qualifications contained in Schedule A of the Medical Act, and it confers upon the holder every privilege as regards practice which can be possessed. In this respect it is exactly on a par with a University M.D., or the Fellowship of any college, granted after examination, and it is totally untrue that it is a mere honorary distinction devoid of legal validity.

The last lesson which may be learned from Mr. Mundella's reply is the lesson which every aspect of medico-educational affairs teaches us, *i.e.*, the utter incapacity and deliberate carelessness of the General Medical Council as to its duties. Twenty-two years ago that conclave voted its disapproval of the sale of Fellowships *in absentia*, and twenty-two years it has slept upon the question, placidly permitting the perpetration of the abuse which it had condemned. We trust Mr. Mundella will appreciate this fact, and will draw from it its legitimate deduction, when we give him the assurance that in almost every item of its functions the General Medical Council has been as culpably lethargic as in this. With such a specimen of miserable incompetency before him, the Vice-President of the Privy Council cannot wonder that the profession is weary of the incubus of the General Medical Council, and wholly contemptuous in its opinion of that body.

## Notes on Current Topics.

### Young Soldiers.

WHETHER or not the system of short service in the ranks has proved a success or signal failure as applied in the United Kingdom is a question for which one reply has been given by officers of great practical experience, another by those most facile in the adaptation of theoretical knowledge; but as applied to India there are no two opinions. The system stands condemned alike in its military as in its medical aspects. With the latter only we are immediately concerned. If, as expressed by the *Homeward Mail* in a recent issue, it is admitted that a bad article is never cheap—that a machine which will not work is dear, though bought at a low price—so, if soldiers, from their youth and physical incapacity, are unequal to the work required of them, it were far better to have none at all; to trust to other means of settling national quarrels; to save the imposts on the taxpayer, and to avoid the drain upon the male adolescents of the country necessitated by foreign service and campaigns. We quote from our contemporary on this subject of young soldiers:—

Even in peace, and under the most favourable conditions, their numbers are thinned to a lamentable extent by disease and death. In the hardships of campaigning they are simply out of the reckoning. They must be left behind, or advance with the certainty of encumbering the force with a daily increasing list of 'sick and unfit for duty.'

But it is not alone in power of resisting fatigue incidental to actual war, and the various influences which produce sickness and death among them in tropical countries that they are wanting; there is every reason to believe that the "staying power" of many men now in

the ranks of our army is less by far than that of men under the system of long service, who, in bye-gone times, fought England's battles. That there is room for such an impression will appear from a comparison such as may readily be made between the proportion of casualties to strength in battle in former times in which our troops stood their ground, and in those of more modern date in which that result was unattained.

#### Legislation for Dentists.

THE Association of Surgeons practising Dental Surgery has creditably performed the duties that attach to it as the rightful guardian of the interests of qualified specialists in dentistry. It is a misfortune, but in no sense a fault, that the efforts made to emancipate the practice of dental surgery from the surroundings amid which it is at present cast, have resulted in miserable failure; and it would be eminently unfair to saddle any other body with the blame which is wholly deserved by the General Medical Council. In his address to the Association of Surgeons practising Dental Surgery, Mr. W. A. N. Cattlin very temperately, but clearly pointed out the present position of the qualified dentist in respect to his professional status, and the injustice done to him by a continuance of the regulations which compel him to be in passive association with persons entirely without legitimate claims to rank as skilled members of the dental profession. Mr. Cattlin's scheme for the future control of medical education and examination is naturally tinged with the special views held by him; but in its general outline it should commend itself to the minds of reformers. There can be no question that a man is not entitled to specialise, is not, indeed, fit to specialise in any subject until he has first grounded himself in the general outlines of his profession. For a medical student to commence his career as one intending to be a dental surgeon, and to prosecute his studies in the sole direction of dental mechanics and pathology, would be an self-evident absurdity. He cannot hope to be in any reputable sense a surgeon-dentist, until he is first a surgeon; and yet the world, and apparently the General Medical Council, entertain an opposite opinion. The whole force of Mr. Cattlin's argument is directed against so false an assumption. He rightly demands that those who elect to specialise in dentistry shall first prove themselves competent to do so by justifying in medicine and surgery, and thus would he, and would we, seek to raise the dental practitioner beyond reproach of being only a tooth-drawer, or a mouth-filler. But this cannot be until there is a legal requirement of *qualification*. To obtain this, legitimate dental practitioners are qualified in employing every means at hand; and that they will yet obtain by right, a full and complete vindication and protection of their position, few will doubt. Mr. Cattlin's address will help this end, and we trust it may fulfil the aim with which it has been written.

#### The Treatment of Phimosis.

AN improved method of operating in cases of phimosis is proposed in the *New York Medical Record*, Feb. 19, by Dr. R. T. Levis, of Pennsylvania. He replaces the ordinary method of cutting away the preputial tissue entire, by a plan whereby only the inner mucous fold of the prepuce is removed. It is often found that this is really the part in-

involved in the morbid process, this latter not extending to the outer part of the substance. When complete circumcision is necessary, as it must be in some cases, then the customary operation holds good; in other cases, however, the proceeding Dr. Levis advises seems preferable; it produces little or no disfigurement, and is both effectual and simple. In the operation he uses an instrument which "somewhat resembles the ordinary mathematical compasses or dividers. The limbs or blades terminate in blunt points, and are deeply serrated on their outer surfaces, with points or teeth set backwards like fine saw teeth, for the purpose of holding the mucous membrane, without the risk of slipping when traction is made. The blades are forced apart by a thumb-screw. In operating, the blades closed to a point, are introduced within the prepuce up beyond the corona of the glans. They are then, by turning the thumb-screw, strongly separated, so as to render the mucous membrane tense. Traction is then made, and the outer elastic skin is drawn back fully, so as to be away from the portion to be excised, and excision is effected by transfixing the prepuce through the middle with a bistoury and cutting externally in both directions toward the blades of the instrument. Any remaining portions of inelastic tissue may be removed with the scissors, and the operation is completed by attaching the cut edge of the skin to the edge of mucous membrane remaining around the cervix by a few stitches. In this manner the inner inelastic mucous membrane may be removed while all the normal outer integument remains."

#### The Health of Bournemouth.

THE annual report of the Medical Officer of Health for Bournemouth shows a very satisfactory condition of sanitary affairs in that town. The registered births number 447; deaths, 264, 148 of whom were residents. This is less by 15 than the number for 1879. Two deaths were from enteric fever, "undoubtedly due to the entrance of noxious sewer gases into the interior of the houses." Thirteen deaths were recorded, all being under twelve months old. The medical officer concludes that this is due to the milk supply, and points to the mismanagement of farmers as a cause of it. The water supply of the town has caused some uneasiness to be felt, and at the time the report was issued an improved service had yet to be made trial of. The question of hotel sanitation is especially important in a place like Bournemouth, and it is therefore satisfactory that these houses of entertainment are subjected to a set of admirable bye-laws for regulating their arrangements. The hotel-keepers, too, exhibit an intelligent interest on the subject of rendering their houses as perfectly healthy as possible, a fact to which the well-being of Bournemouth is, in a considerable measure, due. The report, which is briefly but clearly drawn up, is generally a very satisfactory one, and will encourage many visitors in the coming season to resort to this pleasant seaside town.

#### St. Thomas's Home Hospital.

THE wards set apart at St. Thomas's Hospital, in accordance with the arrangements previously detailed in these columns, were formally opened for occupation yesterday week. The experiment will be watched with considerable interest, not alone by the but also by the governing public.

bodies of other similar institutions, who, if the success at St. Thomas's is sufficiently marked, will be encouraged to augment their receipts by following the same course of action. Whether the plan will prove remunerative remains, of course, to be seen. It could have been wished, however, that greater privacy had been secured to patients than is afforded by a mere curtain partition round the beds. We believe this mode of separation has not been found to answer in other home hospitals. One feature deserves commendation at St. Thomas's—*viz.*, that although a general resident medical officer is always at hand, patients are at liberty to be attended by any practitioner they may choose, paying him, of course, separate fees.

#### Traps for Irish Prison Doctors.

We learn that the General Prisons Board for Ireland, whose attempt to trick the medical officers out of the pensions and emoluments secured to them by the Act of Parliament will be remembered by our readers, have devised a new trap for their surgeons, respecting which it is our duty to warn the profession lest they may give to the department a chance of "serving them out." The Dublin Prisons Board have been sending telegrams to the governors of prisons requiring them to forward, by return, post a report of the dates, hours, and duration of the visits of the surgeons. These telegrams are so timed as to reach the governor about four o'clock in the afternoon when there is a probability that the surgeon is out of the way, and when there is barely sufficient time to write out the report and despatch it by post. Whether or not the governor is explicitly instructed to conceal this transaction from the medical officer we cannot say, but we know that, in the cases of which we have heard, the telegram and consequent report have been carefully kept secret.

We don't suppose that it will matter to the Irish prison surgeons what spy system the Dublin Prisons Board may be mean enough to adopt, but it is as well that prison surgeons should be fully aware that their lords and masters are not at all above employing any system of pimping espionage which suits their purpose. We sympathise with the prison governors who are thus used as *area-men*, and we suggest that if prison officers in Ireland are to be supposed to work together on friendly terms it will be better for the Castle authorities to employ a local process-server for their dirty work than to humiliate the prison governor to such a level.

#### Tenemental Dwelling in Dublin.

The latest report of the Superintendent Medical Officer of health for Dublin states that during the month of January thirty-seven houses and four cellars, unfit for human habitation, were detenanted and closed; and orders for the closing of thirty-four other houses of a similar kind procured from the magistrates.

The denizens of this kind of tenements are of the poorest classes of society. The great majority are labourers and their families; fruit, fish, and vegetable dealers; hawkers, vendors of small wares, and not a few street beggars. Such people unfortunately, too often reduce to a filthy and dilapidated state houses at first tolerably clean and in good repair. When they are turned out of one house

they go into another, and soon render it also "unfit for habitation." For the use of the great majority of these people, cottages ought to be constructed by the municipality, under the provisions of the Labouring Classes' Dwellings Act.

#### The Cork Fever Hospital Libel Case.

THE preliminary skirmishes in the action of *Crawford v. the Cork Constitution and the British Medical Journal*, came off last week in the Dublin Law Courts. Doubtless with the view of opening up the whole question which was disposed of in the fever hospital inquiry, and gibbeting Dr. Jones in the witness box, Mr. Crawford's lawyers had put the whole of the leading articles of which he complains into the legal "statement of claim." On the application, however, of the defending counsel, this ruse has been defeated, and nearly 1,200 words have been erased as being "irrelevant, unmeaning, and embarrassing."

The case will probably be tried at the approaching assizes.

#### Hospital Sectarianism.

A VALUED servant of the Charing Cross Hospital (the Secretary), has just resigned his post. The zeal with which he has for many years fulfilled the duties of his office, will render it a somewhat difficult task to replace him. The governing body of the hospital, however, bent upon increasing this difficulty, has, in its wisdom, thought fit to impose a religious test upon whomsoever may wish to become his successor. The sectarian spirit manifest in the management of the affairs of the Charing Cross Hospital since they have been handed over to the Sisterhood of St. John's House, seems to be on the increase; and this has very probably had something to do with the resignation of the Secretary. Be that as it may, from an advertisement, which has called forth much outside criticism, we learn that the Council now requires that its resident secretary "shall be a member of the Church of England." We may next hear that a similar resolution is about to be imposed upon the medical staff. At all events, the Treasurer and Council have, by their action, quite ignored the fact that the hospital derives support from all sects alike; that it was founded for the cure of the bodily ailments of the sick and needy of all denominations, and is not intended to administer to their spiritual wants. Religious tests are, for the most part, conceived in bad taste, and in a purely sectarian spirit, and when brought into hospital management are literally opposed to the broad principle of Christian charity. Religious restrictions such as we allude to are, therefore, offensive to common sense, and likely to give a dangerous innovation, and very damaging to a voluntary supported institution.

#### The Metropolitan Water Supply.

DR. FRANKLAND, in his report on the Metropolitan Water Supply of last month, says, "the Thames water sent out by the Lambeth, Grand Junction, and West Middlesex Companies was considerably better in quality than that of the previous month, whilst that distributed by the Southwark Company showed a slight deterioration, and the Chelsea Company's water was less pure than in

any month during the whole of last year. With the exception of the Chelsea Company's supply, which was slightly turbid, the water drawn from the Thames was efficiently filtered before delivery. The water derived from the Lea, and delivered by the New River Company, was of inferior quality, and that of the East London better than the supply of the previous month, whilst both waters were slightly turbid, owing to inadequate filtration. and the New River Company's supply contained moving organisms.

The water from deep wells in the chalk sent out by the Kent and Colne Valley Companies and by the Tottenham Local Board of Health was as usual of excellent quality for drinking, and that distributed by the Colne Valley Company, being also soft, was well suited for all domestic purposes.

#### Small-Pox in the Metropolis.

A SOMEWHAT noisy meeting of the managers of the Metropolitan Asylums Board took place on Saturday last under the presidency of Dr. Brewer. There were three resignations of members of the Board, and the recent agitation against the Fulham Hospital by the residents of that district, failed to alter the decision arrived at with respect to small-pox patients. From the reports presented there appears to be a considerable extension of the disease in many parishes. During the past month no fewer than 833 new cases were admitted. During this period 134 have died, 498 have been discharged, and the remainder are under treatment.

Whilst admitting the apparent injustice to the inhabitants of setting up these temporary hospitals for infectious diseases, we can only deplore the necessity which has arisen for them. They must be put somewhere, and if the Asylums Board choose the most eligible and open site for the purpose, we do not see that they can be blamed for carrying out the views of the legislature.

#### Nitrite of Amyl as a Disinfectant of Urine.

M. WEISER claims for nitrite of amyl remarkable disinfecting powers, and employs it as a disinfectant in chronic catarrh of the bladder. Using it as an injection in the proportion of 8 drops to 300 grammes of water. For the disinfection and conservation of urine to be submitted for examination, he prefers nitrite of amyl to phenic acid.

#### Salicylate of Eslerine.

THE salts of eserine are usually unstable; Merck has therefore proposed the salicylate which seems to keep better than its congeners now used in our formulae. (*La France Medicale*). The salicylate of eserine occurs in the shape of needle-shaped crystals, bright and colourless, soluble in 24 parts of alcohol and 130 of water at 16° C. Solutions to one-fiftieth are preserved limpid for a week. They redden slightly in diffused light, but without browning, like solutions of the sulphate. It is not generally necessary in ophthalmic work to use the salt so highly concentrated. The salicylate of eserine contains 66.6 per cent. of eserine and 33.4 per cent. of salicylic acid.

#### Board of Superintendence of the Dublin Hospitals.

HIS Excellency, the Lord Lieutenant of Ireland, has appointed George H. Porter, Esq., Surgeon to Her Majesty, a member of the Board of Superintendence of the Dublin Hospitals, in the room of the late Christopher Fleming, M.D.

WE hear that his Grace the Duke of Newcastle has contributed the handsome sum of 500 guineas towards a new hospital for Newark.

THE foundation stone of a new infirmary building, estimated to cost £32,000 and to accommodate 400 patients of Mile End, was laid last week.

THE Gulstonian Lectures will be delivered at the Royal College of Physicians of London on March 11, 16, and 18, at 5 p.m., by Dr. Coupland. The subject will be "Anæmia."

ST. PETERSBURGH still occupies the unenviable position of having the highest death-rate in the world, viz., 55 per 1,000 of its population. Typhus, according to the last weekly return, caused no less than 78 deaths in that city. The mortality from this disease is also very high in Paris, Madras, Bombay and Calcutta; scarlet fever in New York, and diphtheria in Paris, Berlin and Brooklyn, and small-pox in Philadelphia.

THE rates of mortality last week in the twenty-three large towns of the United Kingdom were:—Sheffield 16, Bristol 18, Portsmouth 18, Leicester 19, Birmingham 19, Hull 19, Salford 20, Bradford 20, Nottingham 21, Edinburgh 21, Plymouth 21, London 21, Wolverhampton 21, Norwich 22, Sunderland 22, Brighton 23, Glasgow 23, Leeds 23, Newcastle-on-Tyne 24, Manchester 25, Oldham 26, Liverpool 28, Dublin 38 per 1,000 of the population.

OF the diseases of the zymotic class in the large towns, last week, scarlet fever showed the largest proportional fatality in Oldham, Portsmouth and Leicester. Of the 24 deaths referred to diphtheria, 8 occurred in London, 6 in Glasgow, 4 in Edinburgh, and 2 in Birmingham. The death-rate from fever, was unusually low throughout the United Kingdom. Small-pox caused 49 more deaths in London and its suburban districts, one in Dublin, and one in Brighton, but none in any of the other large towns.

IN the principal foreign cities, the rates of mortality, according to the latest weekly official return, were:—Calcutta 33, Bombay 31, Madras 48; Paris 30; Geneva 31; Brussels 26; Amsterdam 25, Rotterdam 30, The Hague 21; Copenhagen 21; Stockholm 34, Christiania 21; St. Petersburg 55; Berlin 23, Hamburg 27, Dresden 30, Breslau 27, Munich 37; Vienna 33; Budapesth 37; Rome 29; Naples 32, Turin 35, Venice 23; New York 33, Brooklyn 20, Philadelphia 23, Baltimore 22, per 1,000 of the various populations.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

**THE CHAIR OF PATHOLOGY IN THE UNIVERSITY.**—The report which was current that Professor Gairdner was a candidate for the chair vacant by the death of Professor Sanders is without foundation. We are authorised to contradict the rumour on the authority of the gentleman referred to.

**DEATH OF DR. MACKECHNIE, RUTHERGLEN.**—We very much regret to have to record the death of this young member of the medical profession. Death took place somewhat suddenly on the 28th ult., from a sharp attack of inflammation of the lungs. Dr. MacKechnie graduated M.B., and C.M., at the University of Glasgow only in 1873. He was medical officer for the burgh of Rutherglen, and held several other local appointments. He was much esteemed by the community, and his premature death is sincerely deplored.

**SINGULAR DEATH OF A CHILD FROM SWALLOWING A NEEDLE.**—The strangely erratic course of needles when introduced into the human stomach is well known to medical men. An illustrative case has just occurred in Alexandria, Dumbartonshire. About two weeks ago a little boy, seven months old, was seized with very peculiar and inexplicable symptoms of illness, the only outward indication being irritation and hardness on the left side of the chest. These symptoms increased, and the death of the child ensued. Dr. Alexander McLelland, who had been in attendance, and who had watched the case, was under the impression that a needle had been swallowed. Acting upon his impression a post-mortem examination was made, and in the lower region of the heart there was found, piercing the pericardium, a common sewing needle. It was entire, but perfectly black, indicating that it had been swallowed, found a lodgment in the stomach, and was working its way out. The agony of the child was very great.

**MEDICAL ASSISTANCE FOR THE BOERS.**—We understand that two young gentlemen from the Transvaal, who have been studying medicine at the University of Edinburgh, have been recalled for surgical service in the unfortunate contest now going on between their brave countrymen and this Country. That any such struggle should interfere with the peaceful acquisition of a knowledge essentially human, is a blot on the boasted civilisation of these latter times. Both young gentlemen had arrived at the latter part of their curriculum, and were looking forward to an early attainment of their degree. It is said that a considerable sum of money has been forwarded to them for the purchase of surgical instruments and appliances for use in the field.

**EDINBURGH INSTITUTION FOR INCURABLES.**—The annual meeting of the subscribers to the Institution for Incurables was held on the 2nd inst. at 5 St. Andrews' Square. Lord Provost Boyd in the chair, there was but a small attendance. The report was adopted on the motion of the Chairman, who said there was reason to regret there had been a falling off in the ordinary income. It would, he thought, be very unfortunate if the directors felt themselves compelled to reduce the number of pensioners; but if the public did not come forward in a liberal spirit, such result would be inevitable.

**THE VACANT CHAIR OF MIDWIFERY AT ANDERSON'S COLLEGE, GLASGOW.**—As is too frequently the custom in the medical profession, candidates are already spoken of for this chair, vacant by the death of Dr. J. G. Wilson. It is understood that Dr. Abraham Wallace aspires to the position. Dr. Wallace by education and training is eminently fitted for the position, and he will doubtless be appointed by the trustees.

**NOTES ON TRACHEOTOMY—ON THE MODE OF HEALING IN WOUNDS UNDER ANTISEPTIC DRESSING.**—Dr. David Foulis has reprinted these two papers of his, the former from the *Archives of Laryngology*, and the latter from the *Journal of Anatomy and Physiology*. Dr. Foulis's articles are well worthy of perusal, and are written in pleasing and refreshing contrast to the hyperbolic manifestoes of some of our Glasgow specialists. We do not agree with him as to "the mode of healing in wounds under antiseptic dressings," and cannot coincide with his belief that a blood-clot ever can become organised any more than a dead cat-gut ligature. The condition most favourable to the healing of all wounds is the *simple approximation* of the raw surfaces without the interposition of any chemical or other compound. The effect of carbolic acid upon a recent wound is an immediate chemical one; it coagulates the fibrine and albumen which subserve the purpose of repair, and thus converts them into foreign bodies, and consequently retards the healing process.

**MEDICAL VACANCIES IN EDINBURGH.**—The recent and much regretted blanks, caused in Edinburgh medical circles by death, have already caused a commotion, similar to that which occurs in a disturbed ant-hill. However much religious people may be agreed on a community of interest and habitation hereafter, it is noticeable enough that in sublunary spheres self-interest and partisanship cause them to deploy in an interesting and instructive manner. In Glasgow it is the U. P. body whose coherency and influence can be relied upon by aspiring young medical men; and strange to say, in the metropolis of Scotland—a fact in harmony with its peculiar radicalism—it is the Free Church that is in the ascendant, and in connection with which the chances of medical preferment are greatest. The most coveted prize which Edinburgh offers at present, is the chair vacant by the lamented death of Professor Sanders. For this, Dr. Hamilton, who has undoubted claims to this important chair, is the popular candidate. He is a distinguished pathologist, an excellent lecturer and teacher, is most popular with the students, and has devoted a lifetime to the subject he is so justly solicitous of teaching. We have no hesitation in saying that, all cliques and religious persuasions apart, Dr. Hamilton ought to be elected. Dr. Bryan Waller, and Dr. Dyce Duckworth, are also reported as candidates. We may add, *apropos* of the foregoing, that the politics are complicated. For the late Dr. Handyside's office, we learn that Drs. J. Hunter, Somerville and Cunningham, are candidates.

**HEALTH OF EDINBURGH.**—For the week ending with Saturday, the 26th ult., there were 89 deaths in Edinburgh, and the rate of mortality was 21 per 1,000. One death from fever was reported, and scarlatina proved fatal only in three cases in the old town.

**EDINBURGH UNIVERSITY COURT.**—At a meeting of the University Court of the University of Edinburgh, held on the 28th ult., Charles R. C. Tichborne, Ph.D., Teacher of Practical Chemistry; Hugh A. Auchinleck, L.R.C.P. & S. Edin., Lecturer on Medical Jurisprudence; and W. R. MacNab, M.D., Lecturer on Botany—all of Carmichael College, Dublin—were recognised as teachers of medicine in Dublin whose lectures should qualify for graduation in medicine in the University in terms of Sec. vi. (4), Ordinance No. 8, Edin.

A MEETING of the Victoria (Philosophical) Institute was held on Monday evening, when Mr. R. Brown, F.S.A., reviewed the various theories as to the origin of language, indicating that which rested on the most complete evidence, and was in accordance with the general purpose of creation.

Correspondence.

THE CONVEYANCE OF SEA WATER TO LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been drawn to a letter on the above subject in your issue for February 16th, in which Dr. Drysdale makes favourable comment on the plan worked out by me for the sea water supply of London and other large towns.

Knowing this matter to be of considerable interest to the medical profession generally, many members of which having already spoken highly favourable of a scheme which promises a cheap and constant supply of sea water for the metropolis, the prices now charged by the railway companies being far too high if the article is ever to become of general use, I venture to further trespass on your valuable space with an illustration of the sea water vessel mentioned.

This vessel, designed by me, and patented some months since, is by preference circular in section and sixty feet long, being gradually tapered off at each end. The water is admitted through suitable openings on the bottom of the vessel, which are opened and closed at will by means of the small hand-wheels, A A, shown on the top of the cylinder. Along the inside of the vessel at the top and for nearly the entire length of same an air chamber, M M, is constructed, quite separate from the water-carrying portion of the vessel, and into which water would never be permitted to enter. To this

chamber the buoyancy and perfect safety of the vessel is due, when fully loaded with water, no matter how rough a sea may have to be encountered. It is practically unsinkable.

This form of vessel also is designed with a view to economy of working, as well as to its safety; as in it I claim to be able to convey a maximum quantity of water with a minimum of power—that is, as compared with any other kind of vessel of same dimensions. Another valuable feature is also that the system easily admits of gradual extension, as the demand for the sea water increases.

Figs. 2 and 3 represent a cross section and end elevation of the sea water vessel already described; whilst Fig. 4 shows the mode of handling the sea water on arrival at the depot in London, where it would be pumped up into tanks, and from which it would afterwards gravitate into the water-carts as required for distribution, or the carts themselves could, if desirable, be filled direct from the vessel by means of the pumps on the steam-tug and india-rubber hose pipes.

I hope soon to see this system put in operation, the success of which must be largely dependent on the amount of sympathy and interest shown by the medical profession, and its continued advocacy of the use of sea water; hence I have been induced thus to lay the matter before your readers.

I am, Sir,

Yours obediently,

JOHN BAYES, Assoc. Membr.  
Inst. C. E.

27 Leadenhall St., E.C.,  
Feb., 1881.

THE BURNING OF THE BODY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Of late the question of cremation has been revived, and not only in England, but on the Continent, and in America. A few well-meaning scientists, aware that epidemics and sporadic diseases are traceable to the malaria from cemeteries, especially such as are over-crowded, have evinced a desire to return to the Heathen mode of disposing of the dead. The subject, no doubt, is one that deserves attention, and one, moreover, that would probably be justifiable were there no alternative by which the dead might readily be resolved. That the common system of burial in strong coffins is a horrible device, sustained by crass ignorance and prejudice, is sufficiently manifest. It tends to protract for an indefinite period, the destruction of the body. No one can tell how long *materies morbi* may exist under ground. "If," observes a Transatlantic medical authority, "organic matter can be boiled and frozen without losing vitality, and seeds 3,000 years old will sprout when planted, it would be hardihood to assert that the poison of cholera or small-pox, whatever it is, may not lie for many years

dormant, but not dead, in the moisture and equable temperature of the grave."

Again, a good many, possibly the greater number, of public burial-grounds in the neighbourhoods of cities, are utterly unfitted by reason of the character of their soil, for interment. Soils differ much in the manner whereby they effect destructive changes. Some grounds there are (of which that of Woking Cemetery may be taken as an example), in which a corpse may be completely resolved in three or four years. To effect the like result, other soils (such as those of Brompton and Kensal-Green Cemeteries, twenty-five years, if not a longer period, would be required for the effectual decomposition of the body. It is owing to the latter fact, and that our present cemeterial system is so objectionable and menacing that cremation has been recommended as the quickest way of curing the evil.

There is, sir, a mode of remedy at hand, without going back to the old Roman mode of consuming our dead upon funeral pyres. Dr. Roger S. Tracy, the Sanitary Inspector to the Board of Health, although a pronounced cremationist, is forced to admit that cremation will make its way into general favour very slowly, because inhumation "has the

sanction of ancient usage, and is so intimately connected with the sentimental and religious feelings of the public." Nay, he goes farther, and even points out what he considers "the real advantages of burial as compared with cremation."

The system of earth-to-earth burial, long since advocated by Mr. Seymour Haden, and for over a quarter of a century practised daily in Woking Cemetery, while it answers all the purposes of cremation, is not open to the objections which would beset a departure from time-honoured usage. Dr. Tracy makes favourable reference to Mr. Haden's suggestion of "perishable coffins," the object being to let the earth come in contact with the body as speedily as possible, so as to hasten the putrefactive changes, which under the "earth-to-earth" process of disintegration, are, in nowise, noxious or offensive. Mr. Haden's theory is one to which Aristotle alludes while treating of the "drying and congealing power of the earth." Bodies buried in coffins that will not resist the action of a dry soil, are said to undergo a natural process of cremation, owing to the charcoal which they contain, and by which they become slowly consumed. I shall now conclude this letter, by observing, in the language of Mr. Haden, that the remedy for the evils consequent upon the ordinary mode of sepulture "is not in cremation, but in a sensible recognition of, and a timely submission to, a well-defined law of Nature, and in legislative action to enforce the provisions of that law."

I am, yours &c.,  
MEDICUS.

#### ON THE ADVANTAGE OF FURNISHING CATHETERS AND HOLLOW SOUNDS WITH CLOSELY-FITTING BOUGIES INSTEAD OF WIRE STYLETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—The object I had in view in the above communication was to advocate the extension of a practice which hitherto had only been very partially applied, for up to the present time prostatic and evacuating catheters only have been furnished with bougie stylets. So far as I know Cornay, of Rochefort, was the first to employ a bougie stylet about half a century ago. A little later Civiale used a prostatic catheter fitted with a "gros mandarin," made of whalebone or lead which completely filled the tube. About the same period Mercier invented the "invaginated catheter," and Sir Philip Crampton employed evacuating catheters with bougie stylets.

I was not aware that Dr. Bernard had advocated "armed catheters" for elastic prostatic catheters or I would have referred to his suggestion. His practice, however, would be very objectionable if applied to sounds, for the vibrations of the wire stylet might easily mislead a surgeon; whilst, on the other hand, it is incapable of application to catheters of a smaller calibre than No. 6 English gauge, as a No. 1 English elastic catheter cannot be introduced into a smaller instrument than No. 6. As, however, the smallest bougie is much thinner than the finest catheter, it follows that small catheters can be armed with bougies but not with catheters.

I remain, Sir,  
Your obedient servant,  
W. F. TREEVAN.

10 Portman Square,  
March 5.

#### TRICHINOSIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—In the School of Medicine, Cecilia Street, Dublin, two subjects were dissected during the last month, the muscles of which appeared to the naked eye thickly speckled with sand-like particles of a greyish white colour. The first was a male aged about fifty years, the second a female somewhat older.

I made a careful microscopical examination of the muscles of both, and found the abnormal appearance to be due to the presence of the parasite *Trichina Spiralis*. In the first the trichinae were encysted, being visible in great numbers in the muscles of the extremities, in addition to those usually

affected. In the second case they were both encysted and calcified, being well marked in the muscles of the shoulder. I have to thank our distinguished prosecutor, Mr. John J. O'Hagan (exhibitioner), &c., who furnished me with the various muscles for microscopical examination. It may not be unnecessary to add that as both were dissecting-room subjects, the history of the cases has not been obtained.

Yours, &c.,  
JOSEPH M. REDMOND, L.K.Q.C.P., &c.,  
Senior Demonstrator of Anatomy.

March 1st, 1881.

[The occurrence of these two cases in Dublin just at the moment when the public is engaged upon the subject, is interesting and appropriate, especially as no previous instance of the disease has been recorded in Dublin for some years.—ED. M. P. & C.]

### Obituary.

#### DR. J. G. WILSON, OF GLASGOW.

WE regret to record the very sudden death of Dr. James G. Wilson, of Glasgow, an event which occurred at his residence, Woodside Crescent, on the 4th inst. Dr. Wilson seemed quite well when he rose for the day, and dressed and partook of breakfast. His carriage waited for him at the door, and he was about to set out on his ordinary professional rounds. Before doing so, however, he had occasion to go up to his bedroom, and shortly afterwards a noise, as of some one falling, was heard, and one of the servants hurrying into the room found Dr. Wilson lying on the floor bleeding at the nostrils. Professor Leishman and Dr. Wallace were shortly afterwards in attendance only to find, however, that death had already taken place. Dr. Wilson graduated at the University of Glasgow in 1853, was thus in the prime of life, and evidently robust health, and seemed to have many years of usefulness before him. About a year ago, being somewhat unwell, he requested Dr. Wallace to examine him, the result being the disclosure of what was deemed to be a slight affection of the heart, the development of which probably occasioned his death. Dr. Wilson was the son of Dr. James Wilson, a well-known Glasgow physician, to whose large practice, chiefly in Obstetrics, he succeeded. Dr. Wilson is survived by his widow, a daughter of the late Rev. Dr. Robert Buchanan, of the Free Church College. Of an extremely amiable and active disposition Dr. Wilson enjoyed a large share of public and professional esteem, and his loss is regretted by a large circle of friends. Some years ago he did much of his large practice by deputy, a custom by which, it is well known, he did *not* benefit.

#### DR. WILLIAM M'KINLAY, R.N.

ON Monday, the 21st ult., Dr. M'Kinlay, R.N., died at Fanduit, Strathbraan, in the 64th year of his age. He was a native of that place, and after studying medicine at Edinburgh University he entered the navy in 1838. While staff-surgeon in this service he was also medical storekeeper in the Government Hospital, at Port Royal, Jamaica. He had the honour of being presented with a gold medal for successful treatment of tropical disease, and he wrote a treatise on yellow fever. Nineteen years' service, much of it on a West Indian station, undermined his health, and, to the great regret of those with whom he had been associated, he resigned his commission and returned to his Highland home, where he has spent many years in literary and musical study. His medical skill was always gratuitously rendered to the poor of the district, and he was much esteemed by all who knew him.

Royal College of Physicians of London.—The following candidates having passed the required examinations, were admitted Licentiates of the College on March the 1st:—

Griffiths, Herbert Tyrrell, 38 Devonshire Place, W.  
Holberton, Henry Nelson, Hampton, Middlesex.  
James, Herbert Ellison Rhodes, Bury St. Edmunds.  
James, James Thomas, Ilwajack, Llandoverly.  
Jay, Melville Richard Hindmarsh, Fentiman Rd., S. W.  
Mathews, Sidney Robert Harvey, Buckley.  
Milne, James Kershaw, Royal Infirmary, Manchester.  
Mouritz, Arthur Albert, 23 Richmond Street, S. E.  
Nance, Henry Chester, St. Bartholomew's Hospital.

Shelswell, Oscar Berridge, 28 Trinity Square, S.E.  
Sutton, Samuel Walter, 18 Richmond Terrace, S.W.  
Thistle, Frederick Thomas, 19 Vincent Terrace, N.  
Thomas John, Ystalyfera, Swansea.

**Army Medical Service.**—The following is a list of successful candidates for appointments as Surgeons in Her Majesty's British Medical Service, at the Competitive Examination in London on the 14th February, 1881, in the following order of merit:—

Names.	Marks.	Names	Marks.
Davies, A. M.	2,320	Younge, G. H.	1,675
Hubbard, H. W.	2,290	Clements, W. G.	1,670
Fitzsimon, G. C. C.	2,090	Pattie, W.	1,625
Noding, T. E.	2,065	O'Brien, E. F.	1,620
Yourdl, J. R.	1,992	Thiele, C. W.	1,610
Culling, J. C.	1,910	Nichols, F. G.	1,580
Hackett, R. J. D.	1,955	Cox, T.	1,570
McGeagh, R. T.	1,950	McLaughlin, J.	1,570
Trewhman, G. T.	1,910	Fowler, R.	1,560
Johnston, H. H.	1,900	Craigh, S. H.	1,510
Wilson, E. M.	1,900	Lambkin, F. J.	1,500
Risk, E. J. E.	1,895	Reade, W. L.	1,490
Davies, J. D.	1,880	Peard, H. J.	1,475
Birrell, W. G.	1,850	O'Grady, G. S.	1,455
Dundon, M.	1,840	Rennie, S. J.	1,425
Lingard, T. R.	1,830	Carmichael, J.	1,405
Magrath, C. W. S.	1,810	Farmer, E. D.	1,390
Lane, A. V.	1,780	Craigh, G. W. B.	1,370
Beatty, J. W.	1,740	Wilkison, F. T.	1,370
Weston, G. E.	1,695	Semple, J.	1,345

## NOTICES TO CORRESPONDENTS.

**✉ CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**DR. BUZZARD'S LECTURES.**—We hope to commence Dr. Buzzard's Clinical Lectures "On the Differential Diagnosis between certain Hysterical Conditions and Myelitis" in the course of the present month.

**MR. BERRY WIGAN.**—Your paper "On Surgical Dressings in Private Practice" is marked for early insertion.

**MR. HINDLE** is thanked for his kindly offers.

**A LISTERITE.**—Lawson's absorbent cotton is imported by Burroughs, Wellcome, & Co.; Dr. De Brun's (Swiss) is supplied in this country by Krohne & Seemann. One article is probably as good as the other, both are valuable for surgical dressings.

**BOLDO.**—The leaves of this plant (*Plumum Boldo*), which is a South American drug, have been successfully employed on the Continent as a cholagogue in "hepatic torpor," in atonic dyspepsia, chronic cystitis, and urethritis. The drug is balsamic and carminative.

### A SEQUEL TO DR. TANNER'S FAST.

The following story from an American contemporary is too good to be allowed to pass without further record:—

"From Carson City, Nevada, it is reported that, some short time ago, a lady resident there undertook to preserve absolute silence for forty consecutive days and nights. In vain her family and friends besought her to forego so desperate a resolve. She was not to be moved by their entreaties. At 9 o'clock, on Jan. 20th, being then in robust health, she began to hold her tongue. By half-past ten her pulse had become so weak that the family doctor, upon diagnosing her condition, expressed grave fears for her life. At eleven the action of her heart had slackened to twenty-six beats in the minute, and her breathing was scarcely perceptible; in fact, she was rapidly sinking. As, however, she still persisted in a taciturnity that imminently threatened to prove fatal to her existence, the doctor had recourse to an extreme measure. He instructed one of her near relatives to whisper in her ear a thrilling scandal, by which the reputations of several of her most intimate female friends were irremediably compromised. The effect of this nostrum was miraculous. She sprang from the couch upon which she had hitherto been reclining all but lifeless, hurried out of the house without waiting to put on her bonnet, and ran across the street to the dwelling of a neighbour, to whom she imparted the story in question, with a gush of eloquence that could not be stanchied until half-past six p.m. She has been perfectly well ever since, and is, we are told, deeply thankful for her timely rescue from a situation of mortal danger."

**THE IRISH GRADUATES' ASSOCIATION.**—We are asked to announce that the annual dinner of this Association will be held in London on St. Patrick's Day, March 17, at the Holborn Restaurant, at 7 p.m. Dr. George Paget, F.R.S., of Cambridge, will occupy the chair. Those intending to dine must give previous notice to the Hon. Sec. (See advertisement in another column.)

**DR. ROBERT BAYLON.**—We have no special knowledge of the kind you seek. Probably if you write to her Majesty's Secretary for the Colonies you might obtain a printed schedule which would afford you some, if not all, the required information.

**MONT DORE.**—The Secretary informs us that the first issue of shares in the Mont Dore of Bournemouth (residence for invalids) has been allotted, and that the Institution will shortly be open to the profession and to patients.

**J. O. F.**—Smart, but hardly suitable for our columns.

**AN OUTRAGE.**—We sincerely hope the report is untrue which reaches us by telegram as we are going to press, to the effect that Dr. Barbour and his assistant, Mr. Dyas, whilst attending to the

wounded in the Transvaal, by invitation of the Boers, were arrested, charged with being spies, tied to a wagon for three days, and then shot. The Boers having hitherto shown evidences of their respect for the usages of civilised warfare, we cannot as yet believe this report, although coming from trustworthy authority.

**MR. ALLENSON.**—Competing Essays for the Government prize of £100 must reach the Secretary of the Military Department at Calcutta by the 31st March. If you have not already posted your essay, it can hardly reach there in time.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—This (Wednesday) afternoon, and on Friday, at 4 p.m., Prof. W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."

**HUNTERIAN SOCIETY.**—This evening, at 8, Mr. Clement Lucas, "On cases of Trephining."—Dr. Herman, "On Prolapse of the Ovaries."

**ROYAL MICROSCOPICAL SOCIETY.**—This evening, at 8, Mr. A. D. Michael, "On a Species of *Acarus* believed to be unrecorded."

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.**—Thursday, March 10, at 8 p.m., Microscopical Specimens.—8.30. Discussion on "The Relation between Optic Neuritis and Intracranial Disease," to be opened by Dr. Hughlings Jackson.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—Friday, March 11, at 5 p.m., Gulstonian Lectures: Dr. Coupland, "On Anemia."

**CLINICAL SOCIETY OF LONDON.**—Friday, March 11, at 8.30 p.m., Mr. Berkeley Hill, "On a Case of Fracture of the Spine treated with Sayre's Jacket."—Mr. Barwell, "On a Case of Excision of the whole Tongue by means of a small Supra-hyoid Wound, with remarks on the best material for the Loop of *Ecraseurs*."—Mr. Berkeley Hill, "On a Case of Round-celled Sarcoma, in which no repetition of the Disease took place during the remainder of the Patient's Life—namely, six years after the Operation."—Dr. Radcliffe Crocker, "On a Case of General Bronzing of the Skin without Constitutional Symptoms."—Mr. R. W. Parker will show (1) a Child with Pulsating Tumour on the Forehead, and (2) Three Brothers with Undescended Testicle.

### VACANCIES.

Ardee Union, Collin Dispensary.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, March 10.

Charing Cross Hospital.—Assistant Surgeon on the Staff. Candidates must possess the F.R.C.S. Eng. Applications to the Secretary before April 2.

City of London Lunatic Asylum, Stone.—Assistant Medical Officer. Salary, £120, with board. Applications to Mr. Youte, Guildhall, E.C., before March 16.

Dulverton Union.—District and Workhouse Medical Officer. Salary, £20 for the District, and £30 for the Workhouse. Applications to the Clerk, endorsed "Medical Officer," by March 11.

Durham Union.—Medical Officer for the Eastern District. Salary, £45, with the usual extra fees. Applications to the Clerk before March 18.

Halifax Infirmary.—Assistant House Surgeon. Salary, £50, with board, &c. Applications to the Senior Physician before March 15.

Hull General Infirmary.—House Surgeon. Salary, 100 guineas, with board, &c. Applications to the Chairman of the House Committee before March 21.

Kent and Canterbury Hospital.—House Surgeon. Salary commencing at £80, with board. Applications to the Secretary at Canterbury before March 25.

Oxford, Radcliffe Infirmary.—Resident Medical Officer. Salary, £100, with board. Applications to the Secretary by March 18.

Stockport Infirmary.—Medical Officer to visit Out-patients. Salary commencing at £70, with board. Applications to the Hon. Sec. before March 21.

### APPOINTMENTS.

ANDERSON, H., M.B. C.M., Medical Officer to the Bellinge District of the Wigan Infirmary.

BEEB, W. C., M.B., M.R.C.S.E., House Surgeon to Newark-on-Trent Hospital.

ELLIS, J. L., L.K.Q.C.P.I., Medical Officer for the Maltwyd District of the Dolgelly Union.

EXHAM, A. E. F., M.B., B.Ch., L.M.K.Q.C.P.I., Medical Officer to the Fifth District of the Drayton Union.

FIRMAN, C. G., L.F.P.S.G., M.R.C.S.E., Medical Officer for the Hatfield District of the Dunmow Union.

GARMAN, J. C., L.B.C.P.Ed., L.R.C.S.Ed., Assistant Medical Officer to the Highgate Infirmary.

HOVELL, T. M., F.R.C.S.Ed., Surgeon to the Throat and Chest Hospital, Golden Square, London.

JEFFREYS, R., M.R.C.S.E., Medical Officer to the Districts of Brampton and Walton, Chesterfield Union.

PHILLIPS, L. W. K., M.R.C.S.E., Resident House Surgeon to the Western Branch of the Brighton and Hove Dispensary.

POTTER, H. P., F.R.C.S., Medical Officer for the Workhouse and Infirmary of St. Mary Abbots', Kensington.

WHITE, F., M.B., C.M., M.R.C.S.E., Senior House Surgeon to the Halifax Infirmary.

WINTERBOTTOM, A. T., M.R.C.S.E., L.R.C.P.Ed., Resident Obstetric and House Surgeon to St. Mary's Hospital, Manchester.

### Births.

RENSHAW.—Feb. 27, at Dovercourt, the wife of Bernard Renshaw, Staff Surgeon R.N., of a son.

### Deaths.

CORNISH.—March 1, at Mount Prospect, Transvaal, from wounds received at the battle of Majuba, Surgeon-Major H. Cornish, late of the 10th Royal Hussars, son of C. H. Cornish, F.R.C.S., Taunton, aged 37.

THOROLD.—Feb. 24, at Windsor Villas, Plymouth, Ellis Frederick Thorold, M.A., M.D., eldest son of the Rev. Henry Baugh Thorold, of Hougham-cum-Marston, Lincolnshire.

## The Gulstonian Lectures

ON

### ANÆMIA,

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS,

By SIDNEY COUPLAND, M.D., F.R.C.P.,  
Physician to the Middlesex Hospital.

#### LECTURE I.—ABSTRACT.

THIS lecture dealt with alterations in the composition of the blood and a summary of the known causes of anæmia, which was held to consist in a lowering of the standard composition of the blood in those elements which are destined to promote oxidation, accelerate tissue-change and repair tissue waste. It was pointed out from analyses that hæmoglobin formed by far the most abundant of the constituents of the blood, and the essential fact in anæmia was held to be an impoverishment—either quantitative or qualitative—of hæmoglobin. There is but little known concerning its qualitative changes, although there is no doubt that they play an important part, rendering the hæmoglobin less capable of absorbing oxygen. There are many observations upon the alterations in the quantitative hæmoglobin in disease. Analysis of the blood in chlorosis proved that in that form of anæmia the reduction is mainly in the direction of hæmoglobin, the serum-albumen being of normal, or even excessive amount. The various methods adopted for the estimation of hæmoglobin were referred to, the simplest and readiest being that in which the colour of the blood was taken for comparative tests. The method devised by Quinquad, which is based upon the determination of the amount of oxygen capable of being absorbed by a given quantity of blood, was shown to yield results according with those obtained by other methods, although it does not take into account changes in the quality of the hæmoglobin. No method, however, was capable of dealing with diminution in the total quantity of blood, so that the results can only be used for com-

parison, and are liable to a certain amount of error. Passing to the consideration of the red corpuscles, it was pointed out that mere variations in their number were not always an indication of the blood value, for in chlorosis their number is often large contrasting with the amount of hæmoglobin; and Malassez has estimated the amount of hæmoglobin contained in each corpuscle—an amount not proportionate to the size of the corpuscles. Moreover, of two examples of blood containing an equal amount of hæmoglobin, but differing as to number and size of the corpuscles, the functional value of that containing the larger number is probably greater than the other. Variations in size of the corpuscles were shown to be frequent in anæmic blood, and the remarkable form changes in severe idiopathic anæmia were held to be suggestive of a profound blood-change, although, perhaps, undue stress had been laid upon such alterations, which had been regarded almost as pathognomonic. The development of the corpuscles and their formation in the adult were next briefly described, the organs specially devoted to this function comprising the lymphatic glands, spleen, bone, marrow, and perhaps the liver. The minute and fragile bodies termed "hæmatoblasts" by M. Hayem, were described and the important part assigned to them in corpuscular development by that observer, was mentioned. He had found that they are much in excess of the leucocytes, being in a constant proportion to the coloured corpuscles (viz., 1—20). The manner in which the blood corpuscles are destroyed, and the rapidity with which they are renewed, was next discussed, the chief place of their destruction being probably the liver. A brief reference was also made to variation in the other constituents of the blood.

ANÆMIA, so far, as its ascertained causes are considered, was shown to depend upon a loss of balance between the processes of blood formation and blood destruction, a deficiency in income or excess in expenditure of the blood, or both combined, and its etiology was dealt with under each of these heads. In the first place, deficiencies in quantity and quality of food, especially of the nitrogenous ingesta, were spoken of, and it was pointed out that oxygen was essential in the nutritive processes. The profound anæmia accompanying organic disease of the stomach

illustrated the effects of interference with normal digestion upon the blood, and it was important to eliminate latent disease of this organ before regarding any anæmia as idiopathic. Derangements in digestion are maintained by anæmic state they induce, and hence the liability to mistake effects for causes in regard to this matter. Of other digestive glands the liver and pancreas may, when diseased, cause anæmia, the former, however, in a more complex way than the latter, owing to the part it plays in blood destruction, whereas the pancreas is solely concerned with digestion. Passing to derangements in assimilation and absorption, the marked anæmia of mesenteric disease was held to indicate that the lacteals served for the absorption of proteids as well as of fats, to a greater extent than is generally admitted. Diseases of the blood-forming organs were next considered, and it was pointed out that these might result either in an abundant formation of leucocytes or diminished production of red corpuscles, so that a link was formed between the conditions of leukaemia and anæmia, which are but effects of a perverted action of these organs, the precise nature of which is unknown.

The causes of anæmia, due to excessive blood destruction, were then discussed. Prolonged muscular and nervous activity were shown to be efficient causes, the latter probably from direct interference with blood formation, as well as from consumption of the material of the blood. Excessive secretions, especially in the case of glands yielding highly complex and stable products, e.g., the mammary, were obvious causes of drain on the blood, and from these examples to abnormal fluxes the transition is easy. Actual loss of blood needed no exposition, and Quinquad's observation of the reduction in hæmoglobin following large serous effusions was mentioned. Copious inflammatory exudations, suppuration, and albuminuria are further instances of direct blood impoverishment. The effects of malignant growths in producing anæmia is partly due to the new cell formation, to the involvement of the organs of nutrition, and to direct loss from ulceration and hæmorrhage, but whether there is a cancerous cachexia apart from these effects was held to be doubtful. With tubercle the question is different, and Trousseau's declaration of the existence of anæmia in subjects of tubercular tendency was held to be substantiated. The effects of fever—the essential feature of which is increased disintegration of the tissues and the blood were next pointed out. Reference was then made to the special action of certain diseases on the blood and blood forming organs, viz., scurvy, rheumatism, syphilis, and malarious fever; also to the anæmiating action of such poisons as lead, mercury, and probably phosphorus, the effects of acute poisoning by the last named being those likely to follow impairment of the oxidising power of the blood. Lastly, allusion was made to the discovery of the blood sucking nematoid *Anchylostomum Duodenale*, as explaining cases of tropical anæmia, Egyptian chlorosis, and the fatal disease which attacked the workers in the St. Gothard's Tunnel.

The lecture concluded with remarks upon the influence of age, sex, heredity, occupation, light, air, and temperature, as predisposing to the development of anæmia.

## STIMULANTS IN WORKHOUSES—ALCOHOLIC LIQUORS AS MEDICINES FOR THE SICK.

By NORMAN KERR, M.D., F.L.S., London.

THE supply of intoxicating drinks to the healthy pauper is a separate and independent question, and has nothing whatever to do with the employment of these liquors in the infirmary as therapeutic remedies for the unhealthy. The beer allowance to inmates not sick is one thing, the prescription of alcohol as a medicinal agent in the treatment of the sick is another and a totally different thing. The former is a question of dietetics; the latter, of therapeutics. For the former the guardians are responsible; for the latter, the responsibility justly rests with the medical officer, and with him alone.

The fact of any article of food or drink being useless in good health is no proof that it is valueless in bad health. Some of the simplest and most deadly poisons to the healthy are most potent and effectual remedies when judiciously administered to the sick. No more poisonous agent can be found than prussic acid, yet there are few more useful medicines in the whole range of the British Pharmacopœia. We can, therefore, discuss the medical administration of alcohol to the sick-poor without prejudice, and with no regard to any opinion we may have formed as to the action of intoxicating drinks on the healthy human frame.

From a return relating to the consumption of liquors in workhouses, ordered to be printed by the House of Commons on the motion of Lord Harkness, I find that the total cost for alcoholic stimulants in the year ending Michaelmas, 1871, was, in England and Wales, £115,424. Of this sum, £82,554 was for in-door, and £32,870 for out-door paupers.

The first thing that strikes one is the extraordinary difference in the amount expended by different unions. In Cornwall the amount was £404 for 1,096 paupers, while in Sussex it was £5,071 for 3,246. In Cumberland the cost was over £327 for 632 paupers; in Berks it was more than ten times as much, or nearly £3,490 for 1,738. In the same proportion as Cornwall, Sussex would have expended about £1,200 in stimulants, whereas it really expended considerably in excess of four times that amount. Had Berks paid at the same rate as Cumberland, Berks would have paid £900, whereas it actually disbursed for stimulating drinks nearly £4,000.

In Wales, £46 was expended for 54 persons in Radnor, or at the rate of 17s. per head; there was £66 for 161 in Brecknock, or at the rate of 8s. 2d. per head; and only £56 for 550 in Carnarvon, or at the rate of 2s. per head.

If we analyse these returns for England and Wales, we find no rule for the consumption of strong drinks by either in-door or out-door paupers.

In Berks, the cost for in-door paupers for the twelve months was £1,510, and the number of inmates during the last week of the twelve months was 558, or £2 14s. per head. In Durham the cost was £811, and the inmates 785, or £1 0s. 8d. per head. In Devon the cost was £838, and the number 1,151, or 14s. 6d. per head. In Cornwall the cost was £258, and the numbers 401, or 12s. 10d. per head.

In Wales the Carnarvon guardians disbursed £18 17s. 6d. for 82 in-door paupers, or at the rate of 4s. 7d. each; the Anglesey guardians, £2 19s. 10d. for 12, or 5s. each; the Denbigh guardians, £106 17s. for 54, or nearly £2 each; and the Radnor guardians, £25 18s. 4d. for 6, or £4 6s. 5d. each.

Among out-door paupers the discrepancy is as marked. In England, the return of Lord Harkness informs us that in Berks there was spent for liquor for paupers under the medical care of the district surgeons, £1,978 for 1,180 persons, or at the rate of £1 13s. each; in Leicester, £1,065 for 751, or £1 8s. each; in Cornwall, £145 for 695, or 4s. 2d. each; in Chester, £89 for 1,080 persons, or 1s. 10d. each; in Dorset, £511 for 1,016, or 10½d. each.

In Wales the stimulant expenditure for the out-door poor is considerably varied. In Carmarthen it is £62 6s. for 134 paupers, or 9s. 8d. per head; in Radnor, £20 10s. 6d. for 49, or 8s. 4d. per head; in Brecknock, £26 2s. for 89, or 5s. 10½d. per head; and in Anglesey, £30 3s. for 140, or 4s. 3½d. per head; while in Cardigan it is £2 2s. for 131, or only 4d. per head.

Take an individual union. Rarely do we find the cost for stimulants in any district bearing any fixed proportion to the expenditure in the adjoining districts. I am acquainted with the facts of many unions where this chaotic state of matters exists. Let one example suffice. There are five district medical officers in the parish. In the same period of time, one officer ordered 2 gallons of wine, ½ a gallon brandy, and 1½ pints gin for 488 cases; a second, ½ gallon wine, and 2½ gallons brandy for 505; a

third, 3 pints wine, and 4 gallons brandy for 580; and a fourth,  $3\frac{1}{2}$  gallons wine for 1,010. The fifth ordered neither wine, brandy, nor gin, for 1,086 cases.

I am indebted to the *Leinster Express* of 3rd February, 1872, for a return presented to the Board of the Mountmellick Union, showing the daily average number of persons relieved in 91 workhouses in Ireland during the year ending 30th September, 1871, the cost of wine, ale, and spirits in each union, with the average cost per head on the number relieved, and the number of deaths during the same period in 84 workhouses, with the proportion of deaths to the number relieved.

There was no expenditure at all for alcoholic stimulants in Glenties with a daily average of 120 inmates; in Longford, with 179 inmates; in Armagh, with 344; and in Newry, with 465.

At Lurgan the expenditure was £1 11s. 11d. for an average of 385 inmates, or *three farthings each*. At Mullingar, £1 16s. 3d. was expended on an average of 327 persons, or  $1\frac{1}{2}$ d. each. At Carrickmacross there was £1 2s. for 99 individuals, and at Newtonlimavady, £1 9s. 9d. for 150, being at the rate of  $2\frac{1}{2}$ d. per head at each place. At Clogher there was £1 8s. for 125 paupers, and at Manorhamilton, £1 6s. 6d. for 120, or  $2\frac{1}{2}$ d. at each place. At Bawnboy there was laid out £1 11s. 5d. for 97, and at Gortin, 16s. for 61, or  $3\frac{1}{2}$ d. per head. At Milford, £1 16s. for 95, or  $4\frac{1}{2}$ d. each. At Dungannon there was £4 2s. 5d. for 202, or 5d. each; and at Clonee, £2 11s. for 112, or  $5\frac{1}{2}$ d. At Innishowen (celebrated for its potato) there was £4 7s. 6d. for 136, and at Omagh, £6 15s. for 199, or 8d. each. At Trales there was £15 1s. 2d. for 430, or  $8\frac{1}{2}$ d. each. At Ballyshannon there was £7 19s. 3d. for 179, and at Banbridge, £9 4s. 10d. for 201, or 11d. each.

Ballymasco, with 270 paupers, and Listowel, with 150, expended at the rate of 1s. for each pauper; Dundalk, with 260, at the rate of 1s.  $\frac{1}{2}$ d.; Bailborough, with 132, and Sligo, with 330, at 1s. 1d. each; Stranorlar, with 72, at 1s. 3d.; Mobile, with 175, at 1s. 7d.; Enniskillen, with 240, at 1s. 8d.; Balrothery, with 214, at 1s. 9d.; Belfast, with 2,243, at 2s. 3d.; Newcastle, with 239, and Larne, with 243, at 2s. 6d.; Castleblaney, with 171, and Kilkee, with 98, at 2s. 7d.; Thurles, with 235, and Lisnaskea, with 89, at 12s. 8d.; Castlederg, with 75, at 2s. 9d.; Ballyvaughan, with 150, at 2s. 10d.; Strabane, with 235, at 2s. 11d.; Boyle, with 273, at 3s.; Cashel, with 512, at 3s. 2d.; Parsonstown, with 275, at 3s. 3d.; Lismore, with 195, and Roscrea, with 167, at 3s. 5d.; Donegal, with 78, at 3s. 6d.; Ennis, with 290, at 3s. 7d.; Trina, with 249, and Yougal, with 293, at 3s. 8d.; Limerick, with 1,461, at 3s. 11d.; Clogheen, with 250, at 4s. 3d.; Lisburn, with 247, at 4s. 7d.; Irvineston, with 90, at 4s. 9d.; Letterkenny, with 104, at 4s. 10d.; Borrisokane, with 123, at 4s. 11d.; Athlone, with 305, and Tuam, with 279, at 5s.

At Tobercurry, with an average of 90 inmates, the rate was 5s.  $\frac{1}{2}$ d. per head; at Cavan, with 269, at Clonmel, with 471, and at Waterford, with 840, it was 5s. 31.; at Rathdrum, with 293, it was 5s. 5d.; at Enniscorthy, with 298, and at Granard, with 217, it was 5s. 7d.; at Tullamore, with 353, it was 5s. 7d.; Nenagh, with 394, cost 5s. 9d. per head; Clifden, with 135, cost 5s. 10d. With 187, Edenderry cost 5s. 10d.; and with 82, Killala, 6s. 2d. At Drogheda, with 390, and at Scariff, with 172, the rate was 6s. 4d.; at Ardee, with 265, and at Mountmellick, with 371, the rate was 7s. 1d.; at Croom, with 220, and at Nasa, with 279, and at Carrick-on-Suir, with 351, the rate was 7s. 3d.

Castlecomer, with 146, cost 7s. 6d. per head; Navan, with 200, cost 7s. 10d.; Ballymena, with 123, cost 8s. 4d.; Tulla, with 242, cost 8s.  $\frac{1}{2}$ d. With 169, Cellbridge spent at the rate of 8s. 6d.; with 369, Mallow, 8s. 10d.; with 210, Clonakilty, 8s. 11d.; with 1,933, North Dublin, 9s. 1d.; with 132, Castlebar, 10s. 1d. Kells, with 206, spent 12s. 6d. per head; with 153, Kilmacthomas, 13s.; with 948, Cork, 15s. 2d.; and with 144, Kanturk, 15s. 7d.; At Rathkeale, with 220, and at Urlingford, with 169, the

rate was 17s. 6d. per head; at Donoughmore, with 82, it was £1 5s. 10d.

The expenditure for stimulants in Scotland does not, in any particular workhouse, reach so high a rate as England or Ireland; but, on the other hand, neither does it go so low, there being no Scottish poorhouse where there is an utter absence of drink as in several in Ireland, and so very limited a consumption as is met with in some English parishes. In Scotland the cost ranges from 5d. per head of the total number relieved at Dumbar-ton, to 17s. per head at Thurso. There is before me a return relating to 28 poor-houses in Scotland, of the amount spent on alcoholic liquors for medicines to the sick-poor inmates therein, for the year ending 30th June, 1876. The return gives the expenditure on alcoholic drink per case, not of the total number relieved, but of the number of inmates on the sick-list only.

In Dumbar-ton, with 68 sick cases, the cost was 1s.  $2\frac{1}{2}$ d. per case; with 609 in Edinburgh, it was 1s.  $3\frac{1}{2}$ d.; with 2,449 in Glasgow, it was 1s. 9d.; with 355 in Dundee, 3s.; with 62 in Dumfermline, 3s. 4d.; with 139 in South Leith, 3s. 10d.; with 155 in Aberdeen, 4s.; with 144 in Liff and Benvie, 4s.  $1\frac{1}{2}$ d.; with 146 in Cunningham, 4s. 11d.; with 15 in Upper Strathern, 4s. 11d.; with 144 in Greenock, 5s.; with 129 in Paisley, 5s. 11d.; with 4 in Kirkcudbright, 6s.; with 662 in Govan, 6s. 5d.; with 450 in St. Cuthbert's, Edinburgh, 6s. 11d.; with 857 in the Barony, Glasgow, 8s. 5d.; with 90 in Old Machar, Aberdeen, 14s. 5d.; with 20 in Kincardineshire, 20s. 5d., with 103 in the Abbey, Paisley, 20s. 91.; with 7 in Nairn, 25s.  $1\frac{1}{2}$ d.; with 27 in Athole and Breadalbane, 25s. 9d.; and with 5 in Thurso, 48s. 7d.

A return made to the House of Lords on 11th June, 1877 (referred to in the Report of the Select Committee of the Lords on Intemperance, ordered to be printed 17th March, 1879), shows the quantity and cost of ale, wine, and spirits consumed by in-door and out-door paupers in each union in England and Wales during the year ending Michaelmas, 1876. A comparison between this and the return to the House of Commons in 1871, gives the following results, according to the *British Medical Journal*. In the year ending Michaelmas, 1871, some 10,125,050 pints of ale, wine, and spirits, were consumed by both in-door and out-door paupers, nine-tenths of this being for the former. In the year ending Michaelmas, 1876, the corresponding quantity was 6,964,005 pints, showing an absolute decrease of 3,161,045. As the mean of the number of paupers in 1871 was 1,629,628, and in 1876 730,131, the quantity per head in 1871 was 9 eight-tenth pints, and in 1876 was 9 five-tenth pints. In other words, a decrease of three-tenths of a pint per pauper. In 1871 the cost per head was 2s. 3d., and in 1876 it was 2s.  $1\frac{1}{2}$ d., or a saving equal to  $1\frac{1}{2}$ d. per pauper.

The expenditure on alcoholic stimulants in the metropolis in 1876 was 9s. 10d. for in-door, and 5d. per head for out-door paupers, whereas in the northern division it did not exceed 2s. 11d. for the in-door, and 3d. for the out-door. In Newcastle the cost was 1s. 4d. for the in-door, and 5d. for the out-door; and in Sunderland, 7d. and 2d. respectively. The medical journals pertinently ask, in the language of the *Lancet*, if the paupers in our northern towns do not suffer from the small amount of alcoholic stimulants they receive, and if not, do the London paupers get an excessive allowance?

An interesting return, ordered to be printed by the House of Commons, on the motion of Mr. W. M. Torrens, shows the average weekly cost per head of the inmates of each metropolitan workhouse for the year ending Lady-day, 1869; the average daily number of inmates, distinguishing males from females and boys and girls under sixteen; the number of deaths for the year ending Lady-day, 1869; and the amount expended in beer, wine, and spirits for each workhouse. In these 37 workhouses the total expenditure was £28,250, of which £18,651 was paid for beer, £3,415 for wine, £21 for whisky, £2,664 for gin, and £3,466 for brandy. There were 21,761 inmates, so that the cost per head was £1 15s. 11d. In Bethnal

Green 1,121 inmates cost £1,081, while in Camberwell 518 cost £909, or only £172 less. Bermondsey spent £199 for 479 inmates, while Rotherhithe spent £385 for 219, or almost double the expense for less than one-half the number. If the former had been as extravagant as the latter the liquor bill for Bermondsey would have been £837 instead of £199. Strange to say, while whisky was consumed in but one workhouse, there was only one in which gin was not prescribed.

From a report presented by a special committee to the West Derby (Liverpool) guardians in 1871, we learn that, on an average of two years ending 31st March, 1871, in Liverpool workhouse proper 19,592 cases were annually relieved at a charge for stimulants of £1,590, while in St. Marylebone it cost £2,050 for 3,437 admissions, or £460 more for 16,155 cases less. The value of this remarkable report was enhanced by a synopsis of the returns from 21 unions, showing the yearly cost of stimulants, and the rate of indoor mortality. These returns showed that nothing was expended on intoxicating drinks at Armagh, Lurgan, and Newry. The cost 5d. per head at Edinburgh, 8d. at Preston, 10d. at Birmingham, 11d. at Crumpsall (Manchester), at Liverpool 1s. 5d., at Cork 1s. 6d., at Chorlton 1s. 8d., at Aston 1s. 9d., at Dublin 2s. 4d., at Sheffield 3s., at Islington 5s. 6d., at Lambeth 5s. 9d., at St. Pancras 6s. 5d., at West Derby 7s. 3d., and at Marylebone 7s. 9d.

A second return from another special committee to the same board of Guardians, ordered to be printed Sept., 1880, comprising a statement of the cost of stimulants and rate of mortality in 36 unions during the year ending March, 1880, reveals also startling discrepancies. Liverpool, with an average of 2,797 cases, expended £757 in stimulants; West Derby, on the other hand, with an average of 1,890 cases, expended £2,043. In other words, the latter, with 907 cases less, spent £1,286 more. Greenwich, with 4,821 cases, expended £227, while Brentford, with 357 cases, spent £315. That is to say, Brentford, with 4,464 cases less, spent £38 more. Can anything be more contradictory, confused, and bewildering?

There has been a considerable reduction in several unions in the amount of alcoholic drink prescribed for the sick poor during the last few years. This has probably arisen from the great interest that has been aroused throughout the country in the temperance movement generally, and specially from the prominent manner in which the question of stimulants in workhouses has been discussed by guardians, by medical officers, and by the public over the length and breadth of the United Kingdom. To this unmistakable and very general awakening to the great importance of this deeply interesting subject I am informed, on all hands, that my paper, read to the Annual Metropolitan Conference of Poor-law Guardians, in 1876, under the presidency of the present Secretary for Ireland, Mr. Forster, has largely contributed.

That in many places there has been a decided reduction cannot be disputed. With reference to South Dublin, for example, the *British Medical Journal* in December, 1877, recorded that during the preceding year the consumption of liquor in the workhouse had been much restricted, the restriction being brought about by attention being called to the very large annual expenditure in intoxicating stimulants, and that it had been announced at a recent meeting of the guardians that the expense incurred under this head for the above period had been reduced by over £1,000. Only a few weeks ago the newspapers stated that while the expense in South Dublin for strong drink to paupers that week was 11s. 6d., in the corresponding week of 1879 it was as high as £8 7s. 3d. In a number of workhouses in England and Scotland there has also been a considerable decrease in the quantity of intoxicating drink ordered for the sick.

What results have followed from this reduction? At Wrexham, Dr. Davies reported, on 2nd March, 1876, that

he had ceased prescribing alcoholic drinks for three years, and that during the non-alcoholic period he had been enabled to treat disease with equal success with medicinal stimulants and nutritious diet. There was an increase in the cost of milk, beef-tea, and eggs, but after deducting this, there still remained an annual saving to the ratepayers of £108. Both the doctor and the master reported that the discipline of the house had been greatly improved by the absence of stimulating drinks. The Local Government Board expressed themselves well pleased with what had been done at Wrexham, and thought the system well worth a trial elsewhere. My authority is a copy of the correspondence between the guardians of St. George's Union, Middlesex, and the Wrexham guardians, ordered to be printed by the House of Commons, on the motion of Mr. John Talbot, on 1st May, 1880.

Dr. Webster, Medical Officer to St. George's, Hanover Square, London, in a report presented to the guardians, dated 28th May, 1879, states that on the opening of a new infirmary building he had reduced the consumption of intoxicating drinks very extensively. With an average of 559 inmates, the entire expense for such drinks throughout the twelve months was only £8 3s. 6d. Dr. Webster expresses his great satisfaction with the results, and records a marked improvement in the appetite of aged paupers following the withdrawal of the alcoholic liquor. Some thirty old bedridden women had been stimulated to activity by the discontinuance of their alcoholic "stimulant."

In July, 1880, Mr. Fletcher Horne reported to the guardians of the Barnsley Union that he had decreased the expenditure on intoxicants from £29 to £9 per annum for spirits, from £24 to £4 for wine, and from £18 to £12 for beer, making a total annual decrease of £48 19s. He had proceeded tentatively, withdrawing alcohol from no patient receiving it, but withholding it from new admissions. His year's trial showed him that the patients liked it, and there was no deterioration of health.

At Helston the consumption of alcoholic liquor in the workhouse has been steadily lessened till now it is almost at zero. For a whole year the drink bill, says the *British Medical Journal*, amounted to only 12s.; and for the past six months one pint of brandy, of the value of 4s., was all that was brought into the house. Even this was not used medicinally, but a portion of it was taken by attendants while engaged in nauseating work. The average number of inmates is above 150, and these enjoy good health, making due allowance for such aged and infirm people as are usually found in workhouses. Dr. Wearne, the medical officer, is congratulated by the editor on the success which has attended his management of this department.

(To be continued.)

#### A CLINICAL LECTURE ON HERPES.

By J. MAGEE FINNY, M.D. Dub., F.K.Q.C.P.I.,  
Visiting Physician and Dermatologist to the City of Dublin Hospital.

GENTLEMEN,—A considerable number of cases of herpes having come under your observation during the present and former sessions, and as, in addition to seeing those treated at our special dispensary for diseases of the skin, held each Saturday, you have had daily opportunities of studying this affection in the medical wards, I feel sure a short *resumé* of them, with some practical observations, will prove at once interesting and useful.

There are two very distinct varieties of herpetic eruptions met with, differing in their nature, site, course, and importance. These are *Herpes Catarrhalis* and *Herpes Zoster*.

A few words will suffice to describe the former, and, at the same time, to point out the diagnosis between it and

the other variety, with which, indeed, I may say, it has little beyond its name in common.

*Catarrhal Herpes*—which is also called Febrile or Symptomatic Herpes—is a very common complaint, and one you have seen frequently on the face, and occasionally on the genitals. It is conveniently divided, for the sake of description, according to these regions, into *H. facialis* and *H. progenerialis*, the symptoms of each being very much alike. It is immediately preceded by slight sensations of burning and tingling, and as if the part were swollen and stretched; there is very slight redness, and soon a number of vesicles in clusters appear. These vesicles, usually small in size, though larger than those of eczema, may dry up quickly, or, becoming confluent, form bullæ, filled with opaque or yellowish fluid, and, if scratched or broken, may have an excoriated raw surface.

*H. facialis*—a better name than *H. labialis*—is met with most usually on the lips, at the muco-cutaneous juncture; but it occurs also on cheeks, ears, and nose. Though an accompaniment of an ordinary cold or dyspeptic attack, *H. facialis* is present in pneumonia, cerebro-spinal, intermittent, and scarlet fevers. During the present session you have seen it in both scarlet fever and pneumonia, and you will recollect the different significance which may be attributed to it in these two diseases. In the latter, so usually do the patients who present it recover, that some authorities consider it a most favourable prognostic; while in scarlet fever it is an omen of a severe type, in which nasal discharges, arthritic complications, and a prolonged fever may be expected. The late Dr. Stokes used to lay down, as a maxim worthy of note, that a vesicular complication of fever was ever one of serious import.

The most extensive case of facial herpes I ever met with occurred in a patient, aged 66, who was admitted to this hospital in 1879 for pneumonia, as the whole of his right cheek, extending from the zygomatic arch to the nose was one mass of herpetic clusters, which became confluent. He made a rapid and good recovery. Notwithstanding the frequency of the favourable issue of pneumonia attended by herpes, I would not have you lay too much stress upon the value attaching to this symptomatic rash, inasmuch as most cases of sthenic pneumonia have a tendency to recovery, and many cases in which herpetic rashes are absent do equally well.

The ordinary cases of facial herpes present no difficulties of diagnosis, but you should remember it may attack the mucous membrane of the mouth and palate. Should it be confined to these places, you may find some difficulty in recognising the disease.

Within the last couple of months I came across a rather puzzling case of herpes, in consultation with Dr. William Lane, in the person of a well-known clergyman of this city. The whole soft palate, uvula, and arches of the palate were studded with vesicles standing on a reddened base. At first sight, scarlatina or diphtheritic inflammation passed through my mind; but the absence of the characteristics of those diseases, and the presence of a most copious vesicular eruption on the alæ and dorsum nasi, the upper lip, and the adjoining surfaces of the cheeks and chin made the diagnosis easy.

*Herpes progenerialis*—a better name than *H. preputialis*—usually attacks the sulcus of the glans penis or the reflected portion of the prepuce, though it may also attack the glans, or the outer skin, of the organ. It is a complaint of adult and middle life.

As I have already stated, this affection is, by most authorities, looked upon as a sub-division of *Herpes febrilis*, or, as I prefer to term it (after Liveing), *H. catarrhalis*, differing only in situation from *H. facialis*. It should, however, be noted that some writers deny it has a constitutional origin of a febrile or dyspeptic nature, and they refer it altogether to a local cause, such as coitus, or to the pre-existence of some venereal disease—gonorrhœa, chancroid, and syphilis. Should you desire to extend your inquiries in this direction, I can commend to your notice an article, by Dr. Greenough, in the

"Archives of Dermatology" for January, 1881 (Vol. VII. No. 1).

The symptoms of *H. progenerialis* will usually be slight itching and burning, and on looking at the part, a little patch of redness and swelling will be observed, and standing on the patches may be seen a little group or groups of vesicles, clear at first, but rapidly changing colour to pus.

Should the patient come under medical treatment at this early stage, there will be no difficulty in making a diagnosis; but when the vesicles are broken, and little excoriations and superficial ulcers are formed, it will need much circumspection not to fall into grievous error as to its nature; and should the individual have had impure connection, or should he give a history of venereal disease, the difficulties become proportionately augmented.

The diagnosis between herpes and a specific hard sore is readily made, but not so with respect to a soft ulcer, especially if the prepuce, owing to œdematous distension, be contracted. Under such circumstances a positive diagnosis can only be made after a few days' observation of the progress of the case, and how far it is affected by simple treatment.

Before mentioning the treatment for herpes catarrhalis, I would again remind you of its predilection for the regions of the body where the cutaneous and mucous membranes join. Nevertheless, in some individuals, you will find herpes making its appearance in a patch the size of a five-shilling piece on some part other than at the muco-cutaneous regions, mostly on the trunk, where it follows a similar course to that in the face. I would also impress upon you its great tendency to relapses, as this knowledge will often aid you in making up your mind as to its nature.

The treatment for catarrhal herpes should be of the simplest nature, and, in short, should consist of soothing applications and means to prevent the vesicles being converted into nasty sores by ill-judged irritation and stimulation.

When seen at its very commencement, before the vesicles are at all prominent or turbid, the frequent application of the liniment of belladonna will cause it to abort. It is usually further advanced when first seen, and then such treatment does no good. At this stage I advise that it should be painted with a good coating of flexible collodion, or, if much tingling and itching be present, Ferris' amyloid colloid may be substituted, provided your patient do not object to the pervading peculiar smell of that preparation.

In *H. progenerialis* the collodion is not so applicable, both on account of the numerous wrinkles of the prepuce, and because it will not prevent the inflammatory œdema (and occasionally the balanitis) which may attend it. In these cases, and in the more advanced stages of herpes, wherever it may be, a weak lead lotion, or the lin. calcis applied on a piece of cotton or soft linen, will be most suitable. Should the herpetic abrasions be slow to heal, sprinkling them with calomel twice a day, or painting them with balsam of Peru, will hasten the process.

Whatever you do, you must be prepared for the ailment running its course of seven, ten, or even fourteen days' duration; and in this, as in most other affections of the skin, it is better to do what may seem to be too little rather than err by doing too much.

(To be continued.)

TYPHOID is still very prevalent in Paris and St. Petersburg; small-pox in Vienna, Philadelphia, and Paris. Diphtheria in New York, Brooklyn, and Berlin, and scarlet fever in New York; in the latter city the mortality was greater from diphtheria and scarlet fever last week than in the whole of the United Kingdom.

## Clinical Records.

### CITY OF LONDON CHEST HOSPITAL.

#### Case of Pneumothorax—Autopsy.

#### Under the care of Dr. THOROWGOOD.

JAMES P. B., *æt.* 24, stationery packer, was admitted into the City of London Chest Hospital on June 1st, 1880. He was a fair man of light complexion and medium height, weighing 8st. 3lbs. The family history was that his mother had died of morbus cordis, his father of pleuro-pneumonia (apparently), and one sister of phthisis. His own history is one of good health up till fifteen months ago, when he caught cold, had a cough, with occasional hæmoptysis—described as dark clotty blood—and had gradually got worse.

On admission, the patient was found to be a slightly built man, thinly covered with flesh. The tongue was clean, bowels regular, appetite variable. He complained of dyspnoea on exertion, and a night cough with muco-purulent sputa, often stained of a brick colour. He formerly suffered from night sweats, but they had ceased. The pulse was 126, regular. Temperature, 101·4. Urine alkaline, specific gravity, 1010, containing no albumen.

Dr. Thorowgood made a physical examination of the chest shortly after admission, with the following result:—There was decided flattening of both sides of the chest, and deficient expansion on the left. The breathing on the left was rather harsh, and the voice resonance increased. In the left axilla there was very distinct superficial rubbing, which could be heard as far forwards as the nipple, and below this on the left axillary line a few crepitant sounds. At the left bases the rubbing sound was heard mixed with some crepitation. No tactile vibration was detected. At the left supra-scapular fossa there was decided creaking. Under the right clavicle the resonance was fairly good, but inspiration was accompanied by crepitation.

The patient went on without any marked change in his condition for two weeks. His temperature varied from 101 to 102 degs. in the evening, and underwent morning remission, to normal or 99 degs. On the 14th, however, he was seized with pain in the left side, and a physical examination being made, the breathing on the left was found to be very weak, accompanied by crepitation and creaking; percussion note good. The cardiac sounds were heard loudly over the sternum, but not at all to the left of it. The evening temperature rose to 103·2. On the 16th the left side was hyper-resonant, the breathing weak, and the vocal resonance and vibrations diminished. On the right side small crepitation was heard throughout. The heart was found to be displaced to the right. Paracentesis thoracis was performed on the left side, and about five quarts of air drawn off by the aspirator, the amount being measured by the number of times it was seeming to exhaust the aspirator.

17th.—Paracentesis performed again at midnight, and about 10 quarts of air drawn off, and two ounces of serum. At no time were the signs other than those of absence of breathing, hyperæmia, and displacement of the heart. After each paracentesis the breathing was heard at the left side, accompanied by pleuritic croaking, the heart returning almost to the normal position. At 11 a.m. a valved canula was introduced. The pulse was too fast to count, and there was great dyspnoea and profuse sweating. The finger was applied to the aperture, and the air allowed to escape slowly; occasionally some serum flowed out. Breathing was heard all over the left front; vocal resonance and vibration were perceptible.

18th.—At six a.m. the frothy serum ceased to flow from the canula, though the patient coughed. Vesicular breathing was heard, accompanied by rhonchi and pleuritic crepitation. On the right side rhonchi and small crepitus were heard. The heart sounds were heard loudly to the left of the sternum.

19th.—Yesterday afternoon, and occasionally throughout the evening, frothy straw-coloured serum passed through the canula. Some air escaped from the tube yesterday evening. On right side crepitation and rhonitis diminished, on the left breathing fairly vesicular, accompanied by rhonchus. Heart situated almost in the normal position. Sputa mucopurulent, and this morning mucoid. Patient slept fairly well last night, though somewhat delirious.

21st.—Some air and fluid emerged from the tube yester-

day, and some air came this morning on coughing, along with some frothy fluid.

22nd.—Some blood-stained serum discharged through the tube yesterday. The position of the tube had been changed previously.

23rd.—Air escaped during cough. Some clots in the discharge.

26th.—Still a good deal of air coming through the tube; the liquid discharge is not so red, and is clearer. Slight streaks of blood in the sputa. Cough more troublesome. Crepitation all over chest; no rhonchi.

28th.—Very little discharge, and not so much air coming through the tube.

29th.—Discharge purulent, but sweet.

July 1st.—Dr. Thorowgood examined the patient; no respiratory murmur over the left side, but sounds apparently transmitted from the right.

7th.—Canula replaced by carbolised india-rubber drainage tube, subaqueous.

10th.—About eight ounces of pus in the bottle each morning. Dr. Thorowgood found the right side fairly resonant, and less crepitation accompanying respiration; the left side resonant from the clavicle to the cuneiform cartilage, a few rubbing sounds audible; weak respiratory murmur; cardiac impulse imperfectly felt below the fourth rib, midway between the sternum and the nipple.

17th.—Pulse 118. Tongue red, dry, and furred on dorsum.

August 11th.—Subaqueous drainage tube removed. Sinus found to be 10 in. long projecting backwards along the base of the chest. Air extends freely into the pleural cavity during inspiration. Sinus plugged with carbolised lint. Temperature 101 degs.

12th.—Subaqueous drainage again adopted with the hope of contracting the sinus.

Sept. 3rd.—Cough troublesome last night. No dyspnoea. Some cutting pains in left side. A good deal of air driven out during the night. The drainage tube contained tenacious muco-pus.

4th.—Since yesterday, air driven through the tube with nearly every expiration. Heart heard loudest to the right of the sternum. Hyper-resonance on the left. Metallic crepitation.

7th.—Discharge from tube more abundant.

11th.—Dr. Thorowgood found that the left side was motionless in respiration. Some retraction below nipple line; whole of left chest hyper-resonant. Respiration mixed with râles. Râles over right chest.

Oct. 8th.—The tube came out while patient was asleep; no harm occurring therefrom, the tube was replaced by a piece of lint soaked in carbolised oil. No air escaped from the aperture in ordinary respiration, but a little escaped when patient coughed.

9th.—Left base, resonance impaired. Breathing enormous. Pectoriloquy slight crepitation. Resonance impaired all over left side.

16th.—A small drainage tube kept in the aperture. Free discharge of pus daily.

23rd.—Iodine lotion, one of Tr. Iodi in 16 of water, injected daily through the aperture, and then coughed out by the patient.

27th.—Still hard cavernous breathing between the angle of the left scapula and spine, with pectoriloquy. Elsewhere behind breathing feeble, and accompanied by small, apparently superficial crepitation.

30th.—Purulent discharge diminished. Lotion increased to 1 in 12. The patient continued in the same condition until the 20th of November, when he began to suffer from cough and severe dyspnoea, which he attributed to the foggy weather then prevailing. The dyspnoea continued with a few days' intermission till December 21st, when it became much worse, and he expired.

Autopsy.—Performed the day following that of death, by Dr. West, pathologist. Heart in its normal position. Left pleural cavity obliterated at the apex, all round the margins, but leaving a flat cavity laterally in which the hand might be placed. In the centre of this cavity was the aperture of the puncture, being in the fifth space, and anterior axillary line. Left lung collapsed, covered with a layer of pleura one-eighth of an inch thick, and fairly healthy except at the apex, and the margin of the base. At the apex was one cavity about the size of a walnut, with deeply pigmented fibrous walls, filled with a substance like Roquefort

cheese. At the base there are cavities with similar fibrous walls, and about the same size, but filled with a purulent secretion. They are three or four in number. The largest cavity was at the apex of the lower lobe on its posterolateral surface; irregular, ramified, trabeculated, and large enough to contain a tangerine orange. This cavity is the nearest to the surface, and probably was the one that was ruptured.

Right lung: Dense, partial adhesions at the apex. Lung puckered on the surface with numerous cavities, with pigmented fibrous walls, filled with purulent secretion; in fact, like small chronic abscesses. At one spot a small cheesy, partly calcified nodule. The middle lobe contains several hard nodules of a yellow colour, pigmented, and probably thickenings of the connective tissue. Most of them probably peri-bronchial.

Heart: Right side dilated, otherwise normal.

Intestines: A few ulcers such as are ordinarily called tubercular, situated in the ileum, with small peritoneal tubercles. About two ounces of fluid in the peritoneal cavity. Kidneys congested; epithelium fatty.

Other organs congested.

## Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 11.

The President, JOSEPH LISTER, F.R.S., in the chair.

Mr. BERKELEY HILL on a

CASE OF FRACTURE OF THE LOWER DORSAL AND UPPER LUMBAR VERTEBRÆ, TREATED WITH SAYRE'S JACKET.—RECOVERY, WITH ONLY SLIGHT DEFORMITY OF THE SPINAL COLUMN.

The patient fell twenty feet, and sustained fracture of the laminae of the tenth and other dorsal vertebrae, as far as the second lumbar. Angular projection of these spines, and mobility of two of them. Severe concussion of the spine; paralysis was limited to loss of control of the left lower extremity for about thirty-six hours. Immediate relief to the patient's suffering was afforded by the case, which was put on twenty-four hours after the accident. Patient exhibited 101 days after the accident, having been able to sit up and walk about seven weeks after the injury.

Dr. BUZZARD demonstrated on the patient that the patellar reflex on the left side was much exaggerated, ankle clonus also being very marked, and described by the patient himself as long existing. Dr. Buzzard likened this condition to that produced by Pott's disease of the spine, in which inflammation under the dura mater induces a slight myelitis, succeeded by secondary changes. The boy exhibited was a proof that interruption of motor impulses follow under these circumstances, the growth of a callus at the point of fracture perhaps explaining the phenomenon. There was no apparent paralysis existing, but there was a history of impairment of motor transmission at a previous time. Dr. Buzzard thought the chief interest of the case was in this connection. It admirably illustrated also the beneficial effects possible when Sayre's treatment was adopted.

The PRESIDENT said it was interesting to note the mobility of the spinous processes and laminae of the neural arch. Traumatic acute curvature was a common sequence to serious falls, but need not necessarily be accompanied by paralysis. There was no absolute proof that the patient had not received a direct injury over the spinous processes. The head had been undoubtedly struck, and probably also the back as well, as this only could produce the curvature presented after the injury. He had never seen a case of this kind in which there had not been direct injury of the part. The case was most satisfactory in regard to treatment.

Mr. HENRY BAKER inquired whether the jacket had been employed only while the patient was recumbent?

Mr. BERKELEY HILL said he had not noticed the particular reflex phenomena until Dr. Buzzard pointed them out. He thought it probable the boy had, in falling, struck his spine against the sides of the flaps, so receiving direct injury. The jacket had been worn seven weeks only

Mr. RICHARD BARWELL, F.R.C.S., on

EXCISION OF THE WHOLE TONGUE BY MEANS OF A SMALL SUPRA-HYOID WOUND, WITH REMARKS ON THE BEST MATERIAL FOR THE LOOP OF ÉCRASEURS.

James A., æt. 60, without parental history of cancer, had enjoyed good health till a year ago, when a small lump appeared at the side of his tongue, this was twice removed by ligature, probably inadequately, since on each occasion it recurred quickly.

Feb. 11th.—When admitted into Charing Cross Hospital, the whole tongue, almost to the foramen cæcum, was covered by an ulcerated very dendritic growth interspersed with deep ulceration. Saliva was constantly flowing from his mouth and wetting his clothes. He was feeble from difficulty in eating, and has lost flesh, pulse 108, small and weak, no enlarged glands. The growth is the result of less than seven months.

13th.—The tongue was thus excised. An incision about one-third of an inch long, just in front of the hyoid-bone, exposed the raphé of the mylo-hyoid which being divided bared the edge of the genio-hyo-glossus, these muscles separated with the handle of the scalpel, enabled the operator to feel the base of the tongue and the deep surface of the buccal mucous membrane. A Liston's needle passed into the wound entered the mouth just behind the left last molar tooth, the thread being left. The same was done on the right side, the loop of the cord being in the mouth. To the first cord the end of an écraseur wire (to be described immediately) was tied and so drawn into the mouth, its end being freed from the first thread, was hooked into the loop of the second and drawn round the back of the tongue, out of the wound, and fastened to the écraseur. A Liston's needle was then passed into the wound through the middle of the tongue, and guided by the operator's finger, was made to emerge well behind the disease. This needle guided the wire as it was tightened along the required line. As soon as the back of the tongue was thus severed another écraseur was placed behind the incisor teeth, and its loop pressed well down in the previous section. Thus the tongue was freed from the floor of the mouth and taken out from between the lips.

Mr. Barwell says of his method that if the écraseur be slowly used it is almost bloodless, leaves no mutilation, and that he can remove the tongue from immediately in front of the epiglottis with as much ease as the tip. Moreover, as the sensory nerves of the organ are divided close to the jaw, the patient suffers hardly any pain afterwards, as exemplified by this patient. The wires supplied by instrument makers are of steel, and are tempered; they are too stiff, and indeed the twisted cords of that material are not reliable. He recommended that soft iron cords be used. From Messrs. Newall Mr. Barwell obtains the wire rope used for path fencing and for cables, and separates the strands; each strand consists of six soft iron wires twisted round a thread; it makes a very strong écraseur loop, and is so flexible as to be very manageable. Mr. Barwell also gave reasons for using an écraseur which tightened the loop, not as is usual from one end only, but from both. The patient was shown, the stump of the tongue in very good condition, cut off clean and abruptly at the back. The man was in far better health than before the operation. He had got up from bed on the seventh day, and would have been discharged two days afterwards had it not been thought that the feebleness resulting from the disease might be reduced by a little longer stay in hospital.

Mr. HEATH observed that the chief objection to Nunneley's operation was the obliquity of the cuts employed. He thought Mr. Barwell's plan possessed but little advantage over it, however, especially in regard to the division of the sub-lingual tissues, which by the latter operator were last severed, instead of first, as by Mr. Nunneley. If the operation was carefully carried out, the tongue could be drawn well forward before the écraseur was applied. Mr. Barwell's case illustrated the remarkable rapidity with which the tongue remaining after the operation grew afresh. He himself had, ten years ago, removed the tongue of a man as completely as possible, and when examining him recently he found the organ again almost its normal size. It would be difficult to imagine from the appearances presented by Mr. Barwell's patient that so great an extent of tongue had been cut away.

Mr. MORRANT BAKER explained that the difficulty of operation would be increased by disease of the organ; degenerated tissue would permit the dropping of the needles through it on traction being made, and in the same way disadvantages would attend the introduction of a wire, as suggested by Mr. Barwell. It would be serviceable when the disease was con-

fined to movable parts; but when extensive cancerous degeneration had advanced, the difficulty would be much increased. Such cases were best operated on by stripping up the parts diseased, beforehand. Mr. Baker could not quite understand how the gustatory nerve could be so divided that the remaining portion should be insensible.

Dr. POORE drew attention to the comparative fluency with which persons on whom excision of the tongue had been performed, were often able to articulate words of speech.

Mr. BARKER inquired why it was claimed that Mr. Barwell's operation possessed improvements on the usual one adopted. How, too, did it differ from Cloquet's supra-hyoid operation. Further, he asked if the form of papilloma described is at all common. He had met with it but once; the patient died, and there the growth was found to be epitheliomatous; it was more pedunculated than in Mr. Barwell's case. He would like to hear the opinion of pathologists on the question of character of the growth.

Dr. STRETCH DOWSE asked if the disease was malignant, or as in Mr. Heath's case, normal?

Dr. GILBERT SMITH described the condition of a patient in the London Hospital, with a papillomatous growth in whom the epiglottis was affected. In another case he had met with, a lady, the epiglottis was curved up and back by a papillomatous growth on the tongue.

The PRESIDENT said Mr. Barwell had rendered good service by introducing an improved *écraseur-wire*. He, himself, had frequently been disappointed with wires used in this way. The large amount of tongue possessed by Mr. Barwell's patient was surprising, on the supposition that the organ had been so extensively removed as described. The operation was a great improvement on Nunneley's. In operating for cancer, he (Mr. Lister) divided the jaw in the middle line, and excised the tongue through the opening. This plan afforded an opportunity of leaving so much of the tongue as was unaffected by disease, and further, permitted the easy control of the lingual artery. With the *écraseur* he always felt uncertain.

Mr. BARWELL, in reply, said he had never performed Syme's operation, but had seen it done several times. Though convenient for the surgeon, it left the patient in a miserable condition, often interfering with deglutition, and so hastening death by exhaustion. Paget's operation involved a large amount of hæmorrhage, sufficient, at any rate, to seriously embarrass the operator. In his own cases, as a rule, only three or four drops of blood were lost. The gustatory nerve was divided as it left the gustatory groove at the back of the hyoid bone. Usually a long slender cord remained in the mouth, but in the case under discussion, the end retracted in the groove. The form of the needles served to prevent their slipping; they were large Liston's needles, which were held firmly in place while the *écraseur* was fixed. In one instance, where slipping seemed probable, he introduced a forcep, with which the tongue was firmly held. The base of the portion of tongue removed was quite flat; not slanting, as it would have been, if it had moved during the operation. The portion left in the mouth had grown very considerably since the patient left the hospital; at that time there could be seen only a square gap, at the hinder border of which the tip of the epiglottis was distinctly visible. Cloquet, Mr. Barwell thought, had tied the tongue through the middle with a thread; he did not recollect that his operation resembled the one described. Such growths as that to, remove which the operation had been performed, were of very rare occurrence.

Mr. BERKELEY HILL on a

CASE OF ROUND-CELLED SARCOMA OF THE THIGH, REMOVED BY AMPUTATION OF THE HIP,

in which no repetition of the disease took place during the remainder of the patient's life, namely, for six years; death being caused by tuberculous pyelitis which, during the last three months of her life, formed an abdominal tumour, which was mistaken for a new formation of the original growth.

The PRESIDENT said the case was very interesting as showing that the remedial measures adopted sufficed for the cure of the most malignant form of disease, and proved that our knowledge of such structures was, at present, by no means adequate to enable a definite prognosis to be made of the course of these tumours.

Dr. RADCLIFFE CROCKER read

A CASE OF GENERAL BRONZING OF THE SKIN WITHOUT CONSTITUTIONAL SYMPTOMS,

which had been shown at a previous meeting. The patient

was a sailor, and a native of North Sweden, set 22, stoutly built, and in good health; and the pigmentation came on after exposure to severe weather eight years ago, attained its full development in a few days, and has not extended or diminished since the first week, though he thinks he is paler at some times than at others. The hands, backs of the fore-arms, legs below the knee, and mucous membrane, are unaffected, but all the rest of the body is darker. The pigmentation had no sharp line of demarcation on the limbs and face, shading off to the normal. The general line was a yellowish brown, but the neck, axillæ, nipples, umbilicus, penis, and scrotum, were black. The abdomen, head of elbow, and interscapular region were somewhat darker than the general line; while the face and limbs generally were paler. On the face the forehead was most affected. On the neck and axillæ were closely aggregated papillary growths about one-eighth of an inch long, and the natural lines of the skin everywhere were deepened. Repeated alkaline baths and friction had no effect upon the discolouration. Microscopical examination of the skin of the abdomen showed the pigment to be deposited in the deepest cells of the rete, though pigment granules were to be seen both in the layers and in and about the papillary vessels of the corium. The corneous layer encroached upon the interpapillary part of the rete mucosum so that that part formed a narrow layer of uniform thickness moulded upon the papillæ; these were elongated apparently by the protrusion downwards of the interpapillary processes. The papillary growths upon the neck consisted of an outgrowth of the papillary layer of the corium, involving several elongated papillæ. The pigment was in the same position as elsewhere, but there was no alteration in the arrangement of the epidermic layers. Dr. Crocker was unable to offer any satisfactory explanation of the pathology of this condition, but negated the idea of its being due to phthiriasis, as was suggested when the case was shown to the Society.

Dr. CARRINGTON read brief notes of a similar case.

#### THE NATIONAL HEALTH SOCIETY.

At the fortnightly meeting of this Society, Mr. ERNEST HART, in the chair,

The Secretary reported that Dr. Siemens had consented to give a lecture for the Society in May on "Stoves and Grates." Also, Mrs. Beckton (late of Leeds), would lecture for the Society in the spring. A sub-committee for the removal of dust was appointed. All information on the subject has to be obtained from Paris, Edinburgh, and Brussels. Mr. Noble Smith was appointed hon. sec. for this branch of the Society's work. Mr. J. Campbell, of the Kensington Vestry, and Mr. Edwin Chadwick were elected members of this committee. The petition on the subject of the railway across Wimbledon Common, which has been presented by Dr. R. Farquharson on behalf of the Society was read and printed copies distributed amongst the members.

A pamphlet on the importance of vaccination was read, ordered to be printed, and sent round with a letter to all the Metropolitan boards of guardians. It is hoped the boards will allow the house-to-house visitors to leave them, while the epidemic of small-pox is raging in London, at the houses they call at.

The great desirability of a constant water supply was discussed and a petition drawn up.

On the application of the London Schools Swimming Club for prizes, the Secretary was directed to make arrangements for a meeting, as the committee expressed their wish to assist the Club as much as possible.

The mortality from diseases of the zymotic class was low in all the large towns last week. Whooping-cough showed excessive fatality in Leeds, Edinburgh, and Glasgow. Of the 27 deaths referred to diphtheria, 9 occurred in London, 7 in Glasgow, 4 in Edinburgh, 3 in Portsmouth, and 2 in Salford. The death-rate from fever was generally low, but was proportionally excessive in Norwich, Dublin, and Portsmouth. Small-pox caused 54 more deaths in London and its suburban districts, and one in Birmingham, but none in any of the other large towns.

## Department of Lunacy.

### "OUR SPECIAL COMMISSIONER'S REPORT ON PRIVATE LUNATIC ASYLUMS."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to express my grateful sense and admiration of the fair common sense views enunciated in the series of articles on "Private Lunatic Asylums," by your "Special Commissioner," untainted, as they are, by the medico-trades' union spirit, the large amount of clap-trap advocacy, and anonymous slander of honourable, conscientious men, adopted by some of your contemporaries, both medical and lay. One can understand the "penny-a-liner" sensational principle adopted by the daily caterer of scandal, at a penny a copy, however low, contemptible, or untruthful it may be, provided it "sells;" but that the "organ"—par excellence, does it say!—of the medical profession should resort to the same low tactics, makes one think and feel, that after all there are some sneaking rogues even in that benevolent, well-intentioned profession, who would, having the grand engine for terrorising, the press at their command, make their profit by traducing and falsely accusing men, probably more honourable than themselves, since their petty spite, or wounded self-conceit, can find no other outlet.

Either Dr. Bucknill, and all who support his views, must know, that in saying what they do, they utter a great deal of what is false, or must be speaking upon a subject of the facts of which they have not taken the trouble to acquaint themselves, and by which good men's names are vilified. While no one expects to find private asylum proprietors, as a class, to be angels in disguise, one still is tempted from intimate personal knowledge of many of them, to think that they may be, are in fact, quite as honourable and as anxious to do their duty to their fellow creatures as, (and perhaps with less incentive,) some public officials, or the money-grubbing, self-elected censors of the press.

And then these, would-be, general benefactors (but from self interest, or for any eclair that may arise from such display of concern, oh no) of the whole lunatic race, put forth as their opinion, and as a fact, the advantages, in all and every case, of public over private asylum treatment—I can only say that I have seen for some 30 years the intense anxiety, and interest taken in and felt for the unfortunate inmates of one of the oldest of the latter, and the success that has attended the always enlightened treatment adopted (even before Mr. Wakley published his views in the *Lancet*, or it had become fashionable to take up universal philanthropy) by its recently deceased proprietors; and I also know kindly disposed, benevolent medical men anxious to do all in their power, placed in public institutions with the cases of from 800 or 400 to 1,000 to 1,200 lunatics, to become familiar with, attend upon and treat, but where anything but the merest routine visits and inspection are simply impossible, in place of the minute, intimate knowledge of the 20 or 40 cases in the hands of the proprietor of the private house.

In the public one there must of necessity be a hard and fast routine, which cannot be otherwise, in it; but can be and is, considerably modified in the private house by the proprietor taking the extra trouble implied thereby, to meet the varied whims and wants of those under his care, but which the public officer is less inclined, certainly not necessitated, to take upon himself, having his "rules" and "routine" to set up to, and, doubtless, saving much personal annoyance and exertion.

Again, as to the alteration of the law in reference to the certifying, admission, and facile discharge or restoration to liberty of patients, and the inspection of private asylums, I cannot do better, I think, than refer you to the view taken of the matter by the late proprietor of this place, as embodied in a letter written some 21 years back upon the subject, and that after 20 years' experience of such work, an experience both as regards the "close study of mental disease, and practical acquaintance with the active treatment and personal management of the insane," quite equal to that of the "We" of your ever somewhat crotchety contemporary the *Lancet*.

I am not so sure of the "ample confidence" of the public in the practitioners of medicine, nor as an admirer of the profession, and neither having many and intimate acquaintances amongst its members, do I feel it likely to be increased by

the somewhat fussy over self-assertion of some of its organs and members.

And, then again, in reference to the base insinuations one sees, from time to time, made against the highly honourable men holding the office of Commissioners in Lunacy, that their visitations and inspections are not so thoroughly and carefully made as systematically to increase the liberty of the subject, or enable the patient to regain liberty so soon as he is in a fit condition to do so; knowing what I do of the action of these gentlemen for some 20 years past, I can only say that none but ignorant or unscrupulously mendacious persons could make such, or advance the puerile remedy of doubling their numbers, &c. How such proceeding could make already highly honourable and efficient men more so, is to me absurd. These gentlemen come when, and at what time they please, inspect, and report on what they please, whether to praise or blame; see every patient, and have private interviews with all who desire such, or whom they wish to speak to in private; the whole being a most onerous duty to perform, and rendered more so, since these gentlemen act in the public interest as official censors of gentlemen, no light duty to sensitive, honourable men. That, however, is a position which it is useless to place before the calumniators before mentioned, as they can hardly be expected to understand it, or such feelings.

Though the subject is one fraught with much to expatiate upon, I fear your valuable space will already be unduly encroached upon, but the great interests involved have tempted me on.

I remain, yours faithfully,

Abingdon Abbey,  
Northampton, Feb. 1881.

## The Mineral Waters of Europe.

### THE "MEDICAL PRESS" ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, &c.

WITH

### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.,  
Lecturer on Materia Medica and Therapeutics at the London  
Hospital, Physician to the Hospital for Diseases of the  
Throat, &c.

(Continued from page 168).

### THE ALKALINE WATERS.

We have now facing us the difficulty presented by the subject of classification. In the waters which we have hitherto considered the purgative characteristics were so decidedly marked that no hesitation could be felt in classing them as a group, such simplicity is however at an end, in the waters we are now about to consider. They consist of those waters where the alkaline condition is so strongly marked that we more or less lose sight of the purgative properties—yet it is rarely that an aperient nature is entirely absent from "alkaline waters" so-called.

### Vichy Waters.

If the German and Austrian empires luxuriate in the strong purgative waters, France seems to affect the alkaline waters. Perhaps the most well known are those of Vichy which have greatly grown in importance during the late emperor's reign. The waters of Vichy are frequently compared and spoken of in connection with Carlsbad, but nothing could better show the want of a

good classification than such a confusion of ideas, for the analogy is not borne out by the analyses.

In the Vichy waters the alkalies are in about the proportion of 17 of alkalies to 1 of purgative, whilst the alkaline earthy carbonates are in about the proportion of 3 to 1 of purgatives. Now in the Carlsbad waters this is all reversed. Thus we find that the purgatives proper (we do not include the chloride of sodium), are in about the proportion of  $2\frac{1}{4}$  to 1 of alkaline carbonates, whilst there are eight times the amount of alkaline earthy carbonates. It is very evident that such waters must be different in their action.

In speaking of the Vichy waters we may dwell a little longer than usual upon their source, as independently of their great celebrity, they are typical waters of the class we are now about to describe.

Vichy is situated at the foot of the Amergne mountains in France, and as these springs and the corresponding establishments are government property, and as the bottling is done under government supervision we may presume that every care is exercised in doing full justice to the waters. There are 8 or 9 springs the waters of which are all bottled, but as the area over which they extend is limited it is probable that they have one common origin.

This assumption is more or less borne out by the analyses which show a considerable similarity. We have re-examined four of the most important—Grande-Grille, Hôpital, Hauterive, Mesdames.

The proportion of saline substances brought from the interior of the earth by the waters of the Vichy basin is astonishing. It has been estimated by M. Bouquet at 1,861 tons per annum. The river Allier receives about three-quarters of the precious waste. The geological formation explains, to a certain extent, the remarkable permanence of their chemical composition. But, says the above quoted authority, in speaking of these springs, the mineralisation of Vichy water must be expected to slowly decrease in future—"but without professing to foresee the period at which they will cease to spring forth or will yield water in its normal state, we may safely affirm that such a change will require a series of ages similar to the geological periods, and thus, consequently, thousands of years will elapse before serious modifications, or even an appreciable change will be manifested in the chemical composition, or temperature of these mineral waters."

We are inclined to think that already a change has taken place in these waters as will be evidenced by the four analyses which we subjoin—in no case do we find the analyses give so heavy a result as regards the total solids—when compared with the published results. The discrepancy is not great, but still sufficient to indicate a tendency to a decrease in strength as regards these waters.

In the Thermal establishments at Vichy the flow of the mineral water is about 5145 litres a day (113 gallons) but during the month of July the daily consumption would exceed this limit. To remedy this periodical extra consumption immense vaulted cisterns have been constructed 12 feet deep, in which the water is stored. This of course, enables the proprietors to keep up a supply commensurate with the demand, and the superfluous

water at the hours when there is no great consumption is not lost as it was during the early days of this Thermal establishment. These cisterns will give a supply more constant in its composition for bottling, but if the water was taken from the original analysis from the Springs it would, no doubt, explain some discrepancies.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, MARCH 16, 1881.

### THE PROSPECTS OF MEDICAL REFORM.

MR. MUNDELLA has announced the intention of Government to submit the Medical Bill to a Royal Commission, and we regret that such a decision has been arrived at. We were aware that influential members of the Medical Council and representatives of the Scotch bodies had urged the Government to adopt the course, and we fully understood their object in doing so. They sought in the first place to defeat reform by delay, and to procure an indefinite adjournment of schemes for improvement. For the same reason the same party promoted the Select Committee, but now, when they saw that a few weeks would bring the work of that Committee to an end, they pooh-poohed its re-appointment, and fell back on the new ruse of a Royal Commission. The Medical Council was especially urgent in favour of this expedient, because it had good reason to believe that the Select Committee, having condemned the Council out of the mouth of its own witnesses, was about to report in favour of direct representation; and, therefore, finding the Government very ready to escape from the question, the Royal Commission was started by the obstructive party, and it has been decreed.

While we regret the unnecessary delay which a superfluous inquiry will cause, we are far from regretting the inquiry

itself. Probably it will go deeper in the probing of the medico-educational slough than the Select Committee would have gone, and the deeper its inquiry reaches the more certain and complete will be the resulting reconstruction. The more the sale and purchase of licenses is exposed—the more openly the insufficiency of medical education is displayed—the more freely the light of inquiry is admitted to the obstructiveness and incapacity of the General Medical Council—the more comprehensive will be the reform and the more surely will it come in the end.

As to the trust to be placed in the Royal Commission and its final verdict, all must depend upon the selection of its constituent members made by Government, and if that selection be one-sided or retrograde, we warn Mr. Mundella that such verdict will not settle the question. We do not ask for the appointment of partisans of reform, or of direct representation; but, on the other hand, we may state at once that the profession will not submit to a decision emanating from arbitrators of the high-respectability type, which absorbs most of the Crown seats in the Medical Council. We appeal to the judgment—not of persons of the old *laudator temporis acti* type—but to large minded and liberal educationalists, who are capable of forming an opinion as to what is practicable and just and for the public benefit, untrammelled by effete prejudices or the axiom that what our grandmothers did must necessarily be right.

We are quite sure that the Medical Reform party have the courage and patience of their convictions, and we know that they will never let the agitation for reconstruction rest until a fair reform is achieved. Time is nothing, ultimate success is everything. Let us be firm and untiring—not desperate because the obstructives score a temporary success, but steadily determined to carry the points which all accept as indispensable. An agitation thus conducted never yet failed, and Medical Reform will not fail.

#### THE SMALL-POX HOSPITAL CASE.

THE difficulty of providing in an adequate manner for the wants of the metropolis, in respect to accommodation of those of its inhabitants afflicted with small-pox, is further increased again by the recent decision of the House of Lords concerning the Hampstead Hospital. In consequence of the ruling arrived at, this institution can no longer be made available for the purpose it was designed to serve; a determination which, while it must seriously embarrass the Asylums Board, and may well lead to a multiplication of danger, is yet no more than might have been justly anticipated as the natural end of the wrangle. In a sense, too, it is right and proper; and, in view of the innumerable available sites to be obtained, there seems no excuse for the policy of compulsion to which the parish authorities are apparently committed. A small-pox hospital, so long as the perversity of humanity encourages the existence of the disease, is admitted to be an urgent necessity wherever the nursing of large numbers of people entails risk of infection from isolated cases. This being so, it remains only to select

an eligible site for the hospital; having due regard to convenience of access, to the prejudices of the people, and to the safety of the surrounding neighbourhood. All these, we venture to affirm, may be secured in any one of a dozen or twenty spots within easy reach of any district it is intended to make provision for, as was the Hampstead building. By erecting a suitable hospital in an open situation, in a locality not yet built over, and securing an area of land around it extensive enough to ensure no risk of infection beyond; and, further, barring the progress of house building inside of this limit, future objection against the hospital will be deprived of force. Land-owners not unnaturally feel aggrieved, at the contiguity of an institution specialised as a centre of small-pox infection, with the consequent depreciation in the value of building sites; but it may reasonably be hoped that the near future will see such an intellectual advance among the people as will enable them to perceive the truth now familiar to the medical man, viz., that infection does not extend beyond a certain and moderate distance, in those cases where scientific knowledge directs measures adopted for its destruction. Once regularly established in a locality, and the only prominent building in the locality, such houses as are built subsequently would be erected in the full knowledge of the dangers, imaginary or real, to be dreaded; but owners have a right to complain if, after the erection of their property, there is brought into its midst that of which the mere name will suffice to clear the houses of tenants and leave them empty for years. One point dwelt on in connection with the recent quarrel, viz., the danger of infection from patients during transit, must continue to exist, so long as the official guardians of the people's health are unawakened to the necessity of strict regulations regarding it. The carriages used for the conveyance of small-pox patients to special hospitals should be conspicuously plain, that proximity to them may be avoided; and that, further, the police may be enabled to see that those in charge of them did not, while on this duty, come into relation with the general public, on any pretext whatever. The necessity for special small-pox hospitals, only they will deny, who are blind to every evident need; but the manner of their provision is a legitimate subject of discussion. So long, indeed, as there is any difficulty in the way of rigorously enforcing regulations for immediately isolating cases of small-pox as they occur, under whatever circumstances, so long will there continue to be extreme risk to the unvaccinated, or improperly vaccinated, among the population. Private houses, as hospitals for infectious diseases, are a fatal blunder; but they will continue to exist so long as there is no adequate provision made for the treatment of such cases in institutions specially reserved for them; and notwithstanding the failures attending their efforts up to the present, the Metropolitan Asylums Board must persist in its intention of making ample provision of the kind. Its difficulties, however, will increase instead of diminish with time unless it recognises the essentials to a proper site, viz., open situation, distance from other habitations, and power to forbid future building operations inside of a fixed line round its own property.

## HEALTH OF THE NAVY.

THE Statistical Report on the Health of the Navy in 1879 has been compiled and published with praiseworthy promptitude, considering the amount of labour its preparation necessarily involves. The total force in the service afloat in that year was 44,745, of which number the ratio per 1,000 admitted on the sick-list was 1,116.9; daily sick 44.90, died 8.58, invalided 2.85, equal to a total rate non-effective of 11.43 per 1,000—a most favourable result in any class, but particularly so considering the nature of duties performed by the men of the fleet, and the climates in which they have to serve. Diseases of the febrile class are those by which they most generally suffered; the admissions on this account were 3,292, of which number 67 were fatal, and in 89 cases their subjects had to be invalided. Of enteric fever 73 cases were reported during the year, namely, 6 on the home station, 7 on the Mediterranean, 1 on North American and West Indian, 34 on the West Coast of Africa and Cape of Good Hope, 3 in the Pacific, 6 on the East Indian, 4 on the China, 3 on the Australian station, and 9 in the “Irregular” force—namely, ships proceeding to, or returning to, their several stations, or employed on *special* service. Twelve cases only of yellow fever are recorded, namely, 5 on the North American and West Indian station, 3 on the South-east Coast of America stations, and 4 in the “Irregular” force. Cases of ague were most frequent on the Mediterranean, East India, and China stations. Remittent fever was also very prevalent in the Mediterranean, where it was scarcely to be looked for to so great an extent; also on the West Coast of Africa, its natural home; on the India and China Stations, at the Cape of Good Hope, and in the “Irregular” force. Four cases of cholera occurred, all on the China station; of this number 2 died.

The proportion of cases of rheumatism to strength was 52.78 per 1,000—not by any means a large ratio considering the circumstances of naval life. With regard to venereal diseases the results obtained are certainly remarkable. Compared with the previous year, there was an increase of primary syphilis in the fleet to the extent of 5.75, per 1,000 strength, and of secondary syphilis to the extent of 1.07. Only on two stations was a decrease in this class of diseases observable—namely, Mediterranean to the extent of 1.69, and Australia to no less than 19.59 per 1,000. Elsewhere the increase has been notable, as—On the home station, 6.16; North American and West Indian, 17.73; South-east Coast of America, 29.06; Pacific, 12.82; West Coast of Africa and Cape of Good Hope, 10.78; East Indian, 9.3; China, 5.61; and in the “Irregular” forces 3.6 per 1,000. Throughout the service 12 men were invalided for primary, and 51 for secondary syphilis; there was one death by the latter form. Is it the case, then, that a *pandemic* wave of syphilis has set in? Here is a *bone* to pick, alike by the advocates and opponents of the Contagious Diseases Acts.

#### THE CROWN REPRESENTATIVE FOR IRELAND IN THE GENERAL MEDICAL COUNCIL.

THIS office, vacated by Dr. Hudson as far back as nine months ago, has been filled by the nomination thereto of

Dr. Alfred McClintock, President of the Royal College of Surgeons in Ireland. Shortly after the death of Dr. Hudson, a deputation from the Dublin Obstetrical Society waited on the Lord Lieutenant to represent to him the claims of obstetric science to a special recognition in the General Medical Council. The reply of His Excellency was not favourable. Nevertheless, the views then urged upon Government were warmly seconded by the Obstetrical Society of London, and have had their effect. Many weeks ago it became known that Lord Spencer, in whom—as Lord President of the Council—the nomination lay, had made his choice, but the name of the chosen representative was kept strictly secret for some unexplained reason, and the General Medical Council was allowed to assemble for its dental meeting with two vacant seats. Ten days ago the President of the Dublin Obstetrical Society was officially informed that the name of an obstetrician would be laid before Her Majesty for approval, and this statement was succeeded in a few days by the announcement in the *Gazette* of Dr. McClintock's appointment.

We can with all sincerity congratulate, not only Dr. McClintock, but the profession, on his preferment. As an ex-master of the Rotundo Lying-in Hospital, an author of the highest literary and scientific repute, and a practitioner of long experience, he has long since acquired a claim to consideration, while he possesses qualities specially fitting him for the public position for which he has been chosen. Dr. McClintock has, as Vice-President and President of the Irish College of Surgeons, shown an unusual capacity for administrative work—a clear head, great industry, and conscientiousness in the discharge of duty, and an admirably precise, logical, and eloquent method of speech. On medico-educational questions he has displayed an earnest desire for improvement of the existing condition of affairs, and if he had any individual interest in maintaining the *status quo*, we believe he is not the man to allow personal or pocket considerations to influence him against his honest conviction. We can hardly expect that a representative of Dr. McClintock's seniority will prove to be a very aggressive reformer, or an obtrusive direct representationist, but we cannot doubt that he is well aware of the need of a thorough reconstruction of the Medical Council, and that he will support by voice and speech any reasonable or practical proposal for the resuscitation of that body from the melancholy condition of second childhood into which it has fallen.

If the Crown representative for Ireland speaks at the Council meetings, we shall be disappointed if he does not show that he has something to say, and say it in a comprehensible way—not halt between two opinions—and propose nothing which is impractical, in all of which respects he will be a welcome novelty in the Council Chamber, and his speeches an oasis in the desert of unfruitful talk.

#### INVENTION IN MEDICINE.

MEDICAL science has a peculiar charm for men of luxuriant imagination and feeble judgment. There is nothing easier than to *discover* and to invent, both in medicine and surgery, and this can be done almost not only with entire impunity, but with profit, as the great mass of the

people, and not a few of the profession, too, thirst after the marvellous. A new medicine appears, no matter whence derived, and its wonderful virtues are published with a persistence and a perseverance worthy of a better cause. It is well always to suspect the veracity or the ability of men who discover unlooked-for phenomena from trivial and common-place causes. Hence curers of consumption, cancer, &c., should be scanned with doubtful eye. One man invents a bag for obstetric instruments, another a second bag, a third improves upon the armamentaria possibly by the addition of a toothpick, the bag and contents are faithfully paraded in public advertisements in conjunction with the ingenious inventor's name, and then a newspaper war follows as to the respective claims of the "inventors." In other departments surgical ingenuity is strained in its sublimest heights by the invention of steam engines for the destruction of *hypothetical* entities, and the modern surgeon, like the priest of old, performs his thaumaturgy, amid a cloud of incense, and an abominable smell. A medical contemporary (*The British Medical Journal*) in its last week's impression, says:—"It seems a pity that, by the introduction of two kinds of catgut, additional complications—those recommended by Mr. Lister, and those advocated by Dr. MacEwen, who claims a certain priority in a document with which he has favoured us—should be added to the antiseptic system. As far as we can gather from Mr. Lister's paper, he has already tried combinations of chromic acid with glycerine; but the results have not been the best attainable. Before leaving Edinburgh it was rumoured that Mr. Lister had, by a combination of this kind, obtained a satisfactory article; but he has apparently, since that time, found objections to it. It would be interesting, with a view of deciding as to which is to be the cat-gut of the future, if Mr. Lister would give some details of his experiments, &c." We are very much surprised that it occurred to no ingenious surgeon—Dr. MacEwen, for instance—to suggest that the "cat-gut of the future" might be that of the Kilkenny cat! It ought to hold. So long as we have known anything of Mr. Lister, or his strange theory, it has been characteristic of him to invent to-day, and abandon to-morrow. The result, now is, that everything relating to so-called antiseptic or Listerian surgery is unstable as the wind, and that never was so great a reputation raised on a foundation so chimerical and baseless.

## Notes on Current Topics.

### The Services in Parliament.

In the scheme of army re-organisation recently brought forward by the Secretary of State for War there are several points in reference to the soldier that have an important aspect when considered from a medical point of view. The more important of these are the following:—The term of enlistment is for the future to be twelve years, as at present, but instead of six years, as heretofore, with his regiment, the period will be seven, the remaining five, in place of six, being with the reserve. Instead of enlisting at eighteen, it is proposed that the minimum age of the recruit shall be nineteen, or that he have the "physical equiva-

lent" of that age. No man under twenty years of age or with less than one year's service, is to be sent to India. Recruits to be six months on probation, at the end of which time they are to be medically declared fit for the service before being finally approved. A regiment going out to India will be composed of men of all periods of service from six months to six years; those of the former category, and all who subsequently join a battalion there, will serve their six or seven years in that country until the headquarters return home; this to be after a term of fourteen instead of ten abroad as at present and for some years back.

It is tolerably clear from the nature of these measures that the ground is being cleared for a more easy return to the system of long service, the departure from which during the last few years has proved so great a failure alike in a military and a medical sense, no less than financially, to the country.

### The Wounded in Southern Africa.

"THE wounded at Mount Prospect are not doing so well as could be wished. There are a good many cases of hospital gangrene." Such is the information telegraphed to the *Times*. The occurrence of the disease so called has ever been one of several incidental to the aggregation of large numbers of wounded men. This was the case in the wars that took place in the early part of the present century, and the circumstance was then looked upon as furnishing the strongest possible reason for the modification to a great extent of general hospitals, and their replacement by regimental.

In the occurrence of hospital gangrene at the present time, when hygiene is believed to have attained a state of perfection unknown at a former period, we are inclined to look upon the affection as bidding defiance to all rules of sanitation so long as large accumulations of wounded take place. This is an evil inseparable from the general hospital system, and no doubt the circumstance will once again, as it has already done, force itself upon public attention, and furnish an argument for a return to regimental treatment of wounded soldiers.

### Italian Wines.

SINCE the introduction of the low import duty on foreign wines, Great Britain has come to be regarded as a wine-consuming country worthy the attention of producers in all lands. Wines good and bad, and wines whose connection with the juice of the grape is decidedly remote, find their way here in enormous quantities, until the statistic is fairly puzzled as to their ultimate destination; and the national exchequer is enriched thereby.

The success of the Spanish, Portuguese, French, and Hungarian wines has been so great that reference to them is superfluous; the Greek wines have been favoured by the select few, whilst those coming from the Antipodes and the Cape have failed to meet the popular taste. Italy is now endeavouring to force her way to the front; and profiting by the havoc of the phylloxera during the past few years in the vines of the principal wine-producing countries, she is putting her productions on the English market with every prospect of success. At present Italian wines are but little known in this country, and some years may yet elapse before popular prejudice

is overcome in favour of them; but we say this unhesitatingly that when they are better known the demand will be proportionately great, and "Veltliner," now purchasable for a few shillings per dozen, will rise with the tide to a higher figure. There is also an excellent light fruity Italian champagne in the market at about 30s. a dozen, and a Vermouth in large litre bottles at 36s., which probably will attain the highest popularity of all the Italian wines. The Italian Vermouth has tonic properties of no mean order; it is a totally different article to that nasty French production of the same name, and the pleasant bitter flavour is obtained, we believe, by the presence of certain herbs and grasses peculiar to the locality, before fermentation takes place.

#### Parasitical Pork.

CERTAIN of the daily papers have essayed to calm the troubled minds of lay readers in reference to the disquieting rumours of extensive sales of trichinous pork; and though, from the point of view of the non-understanding paragraphist, it may be a smart thing to ridicule the over-anxious spirit of the medical inquirer, yet, to the reflecting admirer of pork in any form it must be more satisfactory to be told even evil tidings with authority, than the most welcome news authenticated by nothing more than the lively imaginations of journalists. The trichinosis scare is, undoubtedly, well founded; and now that attention is more generally drawn to the danger amidst us, there is not wanting a considerable amount of proof that it is "all too present." There appeared, during the past week, a letter in the *Newcastle Daily Journal* from a correspondent who describes the condition of some American bacon purchased for home consumption, and which was found, when examined microscopically, to be literally crammed with trichina spores. This correspondent aptly remarks: "These parasites are not very desirable food, either cooked or uncooked. The importation or sale of such dangerously diseased meat ought to be rendered impossible. Other countries are prohibiting its introduction from places where the disease is known to exist. We must either do the same or compel all food to be thoroughly examined by competent persons." Another chief reason why imported pork is so commonly infected with parasites is suggested in the same letter—viz., that the meat imported in England is the surplus production of America and Germany; and that since those countries naturally elect to keep for their own use the choicer portions, we get only the inferior qualities, for which, too, dealers exhibit a decided preference. In connection with the same subject, "J. P.," in the *Globe* for March 5, describes the manufacture of sausages from "rotten sheep" as being very largely conducted. He had been assured by a Radnorshire farmer that "there is a greater demand for diseased than for sound sheep; they all go to Birmingham, and we don't quite know what becomes of them." "Sausages," and "food for the poor," are their presumed destination. There is, assuredly, good reason for insisting that governmental supervision over, not only the importation of dead meat, shall be exercised, but also over the condition of all material used at home, for food purposes.

#### "A Terrible Mistake."

THE *Louisville Medical News* records as "a terrible mistake" that two children were recently poisoned at Chicago through muriate of morphia being dispensed by a druggist instead of muriate of quinia. Commenting upon the ease with which, from the similar appearance of the two drugs, the mistake may be made, the paper in question advises the invariable employment of the nitric acid test, before adding the salt to a mixture, and asks, "Would not any druggist do well to exclude morphia by means of a test so easily performed before dispensing any alkaloid of cinchona?" We think he would indeed do well—a good deal better than is to be expected of chemists, at any rate, on this side of the Atlantic. Dispensing assistants may be constituted of material to justify this aspiration in America; they would grievously disappoint the unwary enthusiast who depended on their energy to take any avoidable trouble in this country.

#### The Inhibitory Thermic Centre.

THE question whether there is an inhibitory thermic centre has been the subject of investigation by Dr. H. C. Wood, and the conclusions arrived at have been published under the direction of the Smithsonian Institution. Commenting on them, the *New York Medical Record* says, "The results of Dr. Wood's studies taken in connection with previous experiments by Jürgensen, Traube, Leibermeister, Senator, Sanderson, and others, make our knowledge of the essential character of fever a tolerably complete one." Dr. Wood finds that section of the nervous tract at the junction of pons and medulla, by which of course the vaso-motor centre is unaffected, leads to a large increase of heat production, which latter, moreover, is often independent of any change in either the blood pressure or heart beats—an important consideration. Further experiments at locating this inhibitory centre, led to the belief that it is situated in the pons, and the bearing of this in the production and on the course of fevers is clearly an intimate and noteworthy one, since on it must depend the regulation of the heat in this condition.

#### Fatal Accident to Mr. Spedding.

MR. SPEDDING, the well-known Baconian scholar, has succumbed, in St. George's Hospital, to injuries received by him while walking in the street—a hansom-cab having knocked him down, and run over him. The left ear had been almost entirely torn away; and Mr. Holmes is of opinion that fracture of the base of the skull had also occurred.

#### Hot Water Compresses in Tetanus.

WARM or hot baths in tetanus have frequently been found to give great relief; but in many circumstances it is practically impossible to give them. In view of this, in the treatment of tetanus and trismus, Dr. Sporer has successfully employed hot-water compresses. He dips a large enough piece of coarse flannel in water of a temperature which can just be borne by the hand (50 dg. to 55 dg. C.), and applies the compress to the occiput and along the spine.

### The International Medical Congress.

THE Museum Committee announces that, in connection with the Congress, a temporary museum will be opened in the rooms of the Geological Society. All objects of novelty or rarity having reference to the processes of disease or the results of injury, will be acceptable for exhibition. The committee in charge of it will be especially obliged by the loan of drawings, photographs, and models, for the efficient display of which careful arrangements will be made. The following are some subjects to which it is intended to devote special attention :—

1. *Injuries to Bone*.—Fractures of carpal end of radius, recent and old—specimens proving bony union after transverse fracture of patella—rare forms of fracture, dislocation, and separation of the epiphyses; repair of skull bones after injury, especially of basis cranii.

2. *Bone Disease*.—Osteitis deformans; collections of scoliotic and other pelvic deformities; specimens of necrosis without suppuration; mollities ossium; specimens of rickets in the lower animals.

3. *Results of Operations*.—Arteries after catgut or other ligatures; osteotomy for genu valgum; specimens showing repair after excision of joints.

4. *Joint Disease*.—Charcot's joint disease; rare forms of rheumatic arthritis and gout.

5. *Skin Disease*.—Rodent ulcer and allied forms of cancer of skin; molluscum contagiosum.

6. Parasitic and other diseases which occur solely or especially in particular countries; madura foot; ainhum, &c.

7. Lymphadenoma.

8. External hydrocephalus.

9. Rare and important specimens of comparative pathology from the lower animals, or from vegetables.

Specimens, drawings, &c., of any other disease of special and peculiar importance, will also receive the careful consideration of the committee.

The Museum Committee will also be glad to receive and exhibit all preparations and drawings used for the illustration of papers in the various sections, or having reference to the subjects discussed.

Arrangements will be made for the exhibition in groups, on special days, of which due notice will be given, of *living examples of certain rare diseases, &c.* The committee will be much indebted to all who can afford help in this department. Should any member of the Congress desire to exhibit a living example of any very rare malady not here mentioned, it is probable that by early application facilities may be afforded. In all cases in which a series of living specimens is collected, there will also be a special group of drawings and preparations to illustrate it.

The following are the subjects selected by the committee for illustration, in this manner :—

1. Addison's disease (bronzed skin and disease of suprarenals).

2. The coincidence of true gout and rheumatic arthritis.

3. Charcot's joint disease.

4. Myxœdema.

5. Syphilitic bone disease in children, simulating scrofula and rickets.

6. Mollities ossium.

7. Primary muscular atrophy.

8. Rupture of brachial plexus or other large nerve trunks.

9. Scleroderma or morphea.

10. Keloid of Alibert, especially with reference to its spontaneous disappearance.

11. True leprosy.

12. Lupus erythematosus.

13. Xanthelasma.

All communications regarding this section should be addressed to H. Clutton, Esq., 16 Palace Road, St. Thomas's Hospital, London, S.E.

### The French Army Medical Service.

AN important step has been taken by decision of the *Senat* to emancipate the *Service de Santé* of the French army from the control of the Intendance. For many years back the efficiency of the power was paralysed by the state of subordination to *commisariat* in which it was so long held. Now, at long last, brighter days are before it; and we can congratulate our *confrères* on the prospect.

### Election of Physician to St. Vincent's Hospital, Dublin.

DR. M. F. COX, of Sligo, has been appointed to the Physicianship of this Hospital, rendered vacant by the death of the late lamented Professor Cryan, F.C.P. Dr. Cox was a very distinguished student of the Catholic University, where he gained scholarships and numerous prizes, and was also auditor to their Historical Society. In their Medical School he was equally successful, and in St. Vincent's Hospital he gained, by competitive examination, the Resident Pupilships and the Senior Prize in Clinical Medicine and Surgery. He is connected with the Irish Colleges of Physicians and Surgeons, and is a Member of the Royal Irish Academy. He has been for several years practising in Sligo. While doing justice to Dr. Cox's well earned claim to consideration in his student career, we cannot hesitate to repeat our deprecation of the system pursued at St. Vincent's and occasionally in other Dublin hospitals of lifting gentlemen of very limited experience into the responsible charge of wards full of sick and dying patients. We do not hold wholly responsible for this the Medical Board of St. Vincent's, who have the prerogative for appointment, nor the Sisters who choose one from the names so elected, because we do not see that, generally speaking, any course is open to them, if they desire to choose a young man, but to choose an untried and inexperienced one. There does not exist in Dublin—and more's the pity—the reasonable and salutary system which obtains in London of appointing one or more assistant physicians and assistant surgeons to each hospital. The function of such officers is generally fulfilled, often very unsatisfactorily, always with risk to the patient, by resident pupils whose education is usually incomplete, and whose responsibility is undefined, and these resident pupils are rotated out of office each year and other beginners got in. This plan is objectionable in every sense, and it affords no probation stage in which the fitness of an hospital surgeon or physician may be tested, and it is upon the managers of hos-

pitals who permit such a system to continue that the blame rests of the appointment of immature medical officers. At all events, it is clearly wrong that young gentlemen who are not familiar with the responsibilities of medical practice should be placed in charge of the lives of the sick poor in hospital, and a system which makes this an everyday abuse in Dublin cannot be defended.

### The Spoon-Feeding of Coroners' Juries.

WHATEVER may be the practice elsewhere, undoubtedly Dublin is the *locus* of a system of substituting coroners' notions for the opinions of juries. We have noted more than once the disposition of the coroner for this city to make himself judge, jury, and law-giver in the cases which it is his duty to investigate, and our attention is called to the comprehensiveness of this functionary by an unusually flagrant exercise of his authority last week. A man fell into a dock, and on being taken out was found to be dying. Messengers were dispatched for various doctors, and it was reported that one medical practitioner refused to come unless promised his fee; but another did attend, and it does not appear that any delay resulted from the refusal. Thereupon the coroner is reported to have delivered himself of a speech to the jury as follows:—

"A coroner's court was a social court that derived much of its influence from its power of bringing public opinion to bear on matters not strictly within the power of the law, and therefore the jury had a right to express their opinion on the conduct of the doctor if they thought fit. In the course of many years' experience he was happy to say he had never known an instance of a medical man refusing to attend promptly to an accident until this case."

But the coroner was not satisfied with thus thrusting his own ideas upon the jury. He considered that any expression of censure on the medical man who did not come should be coupled with a commendation of the doctor who, in the cause of humanity, so promptly attended.

Thus instructed, the jury—probably constituted of dock labourers, corner boys, and other equally discriminating personages—were induced to pass a public censure upon the medical practitioner who was denounced. A more unjustifiable abuse of judicial position we have never known—stepping outside the very limited duty which the law entrusted to him, the Dublin coroner elects himself the arbiter of the elegancies of professional practice, and through the mouths of a dozen poor ignorant creatures, dictates a vote of condemnation, for which there was no sufficient ground in the testimony before him.

We take the liberty to inform this functionary that he totally misconceives both his authority and his position when he elects himself the dictator of a "social court," or presumes to supervise the conduct of professional men. On the part of the profession we repudiate his opinions, and decline his patronage, and we recommend him to confine himself to his legitimate business of finding out the causes of death, for the better performance of which duty there is much room in the city of Dublin.

### The History of Dental Registration.

IN a handy volume just issued by Mr. Miller on behalf of the General Medical Council, the minutes of the whole of its dental proceedings, from January, 1879, to the present time, are detailed, and he has placed at the disposal of the public the records which would otherwise have been difficult of access amongst the other proceedings of the Council.

We cannot recommend the volume as a pleasing retrospect of progress achieved, or as an encouragement to those who aspire to raise the status of the dental profession. It is useful, however, not only as a book of reference, but as a history of mistaken legislation and muddled administration. As such the book has no equal.

### The Trichinosis Craze.

THE whole of Europe seems suddenly awaking to a scare about the trichinæ in American pork, one government after another becoming affected to such an extent as to threaten the total importation of hog's flesh from the United States. In France, as we stated last week, it has been absolutely prohibited; several smaller States have followed the example, and there seems every likelihood that Spain, which consumes a very large supply annually, will do likewise. Last week the discovery of trichinæ spiralis was made in six bodies of persons of the lower classes who died in the Madrid hospitals. Upon the President of the College of Surgeons informing the authorities of the fact, Count Xiquena and the Alcalde immediately gave stringent instructions to the municipal officials to examine the pork which enters largely into the consumption of the lower classes in Spain. It seems that besides the pigs killed in the municipal slaughter-house under supervision, more than twelve thousand are annually consumed, without proper examination, in suburbs and villages around Madrid, and smuggled in for the lower classes. There are also large deposits of salt pork and preserved meat from the United States largely used for provincial consumption; and the Madrid press believe that the greater part of these imports come in by contraband, and without proper inspection, as it is sold very cheaply, to the lower classes principally. In Great Britain we have not rushed into the scare, and the Local Government Board has contented itself by issuing a Circular to the sanitary authorities throughout the country, suggesting that special precautions should be taken in regard to foreign pork and bacon. Attention is called to sections 116—119 of the Public Health Act, 1875, relating to unwholesome meat; which the inspectors are enjoined to use special vigilance to carry out.

### The Value of the Dentaphone to Deaf Mutes.

IN the December number of the *Archives of Otology*, Dr. E. Triebel, Superintendent of the Berlin Royal Asylum for the Deaf and Dumb, gives the results of experiments with the dentaphone on the inmates of that institution. Having seen it stated in a prospectus of the American Dentaphone Company in Berlin, that "persons whose sense of hearing was defective, or indeed those who were perfectly deaf, could use this instrument with the

utmost facility, and with astonishing results," he was naturally anxious to convince himself of its actual value. He therefore made extensive and critical experiments; first on persons entirely deaf, those who had been born so, and others who had lost their sense of hearing in early childhood. "The result was utterly negative, inasmuch as not one out of the above-mentioned could hear any sound whatever with the aid of the dentophone even when the greatest effort was employed by the speaker."

The author then selected a large number of persons who still possessed some sense of vocal sounds, choosing some who had been born deaf, and others who had been afflicted later. The result was precisely the same. He next proceeded to experiment with those still possessing the capacity for recognising words, and he discovered "that they could only understand very loud spoken words by means of the dentophone, but with no greater distinctiveness, and with no more facility, than if the words had been spoken in the ear without any instrument at all."

The conclusions arrived at are that where deaf mutes are concerned, the dentophone—in its present condition at least—cannot be put to any practical use, even as a means of advancing articulation. Judging also from four experiments which he has made on healthy persons, Herr Triebel is inclined to doubt whether the instrument can give any noteworthy assistance to any one whose hearing is in the least defective.

#### New Method of Trephining the Mastoid.

DR. BAGROFF'S method of trephining the mastoid is by combining the use of the galvano-cautery with that of the gouge. As soon as the bone is laid bare by incision of the skin and periosteum, the first application of the galvano-cautery is made for a few seconds until a blackish eschar is produced. The bony tissue thus becomes friable, is attacked with the gouge, and when the whole of the calcined layer has been removed the cautery is again applied. The alternate action of cautery and gouge enables us easily to lay bare the mastoid cells without danger of lesion of the venous sinus, and facilitates the change of direction one may wish to make in the channel which is established.

Bagroff thinks this proceeding would be applicable to the ablation of osteomata from the auditory meatus. Local anæsthesia having been produced, the galvano-cautery should be applied at the most accessible point. An eschar being produced, one may cut into the tumour by means of a special gouge. By a combined use of these two means, the osteoma may be pierced from side to side, when its extirpation becomes easy.

#### Resorcine.

At a recent meeting of the Paris Hospital Medical Society, M. Dujardin-Beaumez stated that he had been making experiments with this new production, obtained from *assafoetida*. It is a crystalline body, white, odourless, soluble in all proportions. It stops fermentation of all albuminous substances of milk, urine, &c. The Germans have used it principally for dressings. There

are great analogies between resorcine, carbolic acid and salicylic acid.

In ulcerations of all kinds it may be used as a topical application; M. Beaumez has dressed with it chancres and mucous patches and obtained satisfactory results. In diphtheria it may replace carbolic acid, of which it has not the unpleasant smell. It may be useful in local affections of the stomach.

Resorcine is poisonous in doses exceeding 6 or 7 grammes, the toxic effect then produced being similar to those of carbolic acid.

M. Beaumez thinks this substance may give good results in surgery as an antiseptic, but in medicine, where 2 grammes may be given without danger, its efficacy has not yet been demonstrated.

#### Resection of the Small Intestine.

M. KÆBERLE, of Strasburg, recently brought before the Paris Academy of Medicine (*La France Médicale*) a case in which he had resected two metres (2 yards and 6 inches) of the small intestine. The patient, a girl, 22 years of age, had for many months suffered from attacks of internal strangulation. She came to Strasburg in November, four weeks after the last attack. Colic was then very severe and resisted all methods of treatment. The belly was much extended, and the pain appeared soon after meals. It was difficult to determine the cause of obstruction, and M. Kæberlé performed gastrotomy. The loops of small intestine exposed in the wound were distended and abnormally vascular. There was a cicatricial obstruction, in front and behind which the intestine was dilated; this led one to suppose a second cause of obstruction, and such was found with  $1\frac{1}{2}$  metre intestine between the two structures. Not to interfere was to expose the patient to certain death; resection of the intestine seemed the only thing applicable. M. Kæberlé performed this and resected the cut extremities of intestine. At the end of a month the patient was perfectly cured. Lister's dressing was not used.

THE Lord Mayor presided at the opening ceremony of the London Temperance Hospital, situated in the Hampstead Road, on March 4th, at which a large and influential gathering took place.

WE have pleasure in announcing that Dr. A. H. McClintock has been appointed a member of the General Council of Medical Education of the United Kingdom in the place of the late Dr. Alfred Hudson.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population were—Brighton 17, Leicester 18, Bristol 19, Birmingham 21, Leeds 21, Hull 21, Sunderland 21, Sheffield 22, Newcastle-on-Tyne 22, Oldham 22, Portsmouth 22, Edinburgh 22, Glasgow 22, London 23, Nottingham 24, Bradford 24, Norwich 24, Plymouth 24, Manchester 25, Salford 25, Wolverhampton 25, Liverpool 26, and Dublin 36.

In the principal foreign cities, the rates of mortality, according to the latest weekly official return, were:—

Calcutta 37, Bombay 35, Madras 39; Paris 29; Geneva 19; Brussels 27; Amsterdam 27, Rotterdam 29, The Hague 27; Copenhagen 27; Stockholm 28, Christiana 16; St. Petersburg 54; Berlin 22, Hamburg 21, Dresden 24, Breslau 24, Munich 37; Vienna 31; Buda-Pesth 37; Rome 28; Naples 30, Turin 38, Venice 22; New York 34, Brooklyn 22, Philadelphia 23, Baltimore 19, per 1,000 of the various populations.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

**EXTENSION OF MEDICAL BOYCOTTING IN SCOTLAND.**—Some time ago Dr. James Diamond, Muthill, raised an action in the Perth Small-Debt Court against James Millar, farmer, Muirside, Muthill, concluding for £3 10s. for medical attendance and medicines supplied to the defendant's daughter. The defence stated was that Dr. Diamond had improperly treated the disease, he having supposed that it was diphtheria, while, in point of fact, it was only a simple cold; and that, in addition, the account was over-charged. After several discussions before Sheriff Barclay, the case was remitted to Dr. Bramwell, to make all necessary investigation, and to report (1) whether the patient suffered from diphtheria, or merely from a sore throat, and (2) whether the charges made were, in the circumstances, fair and reasonable; and, if not, what charges should be allowed. Dr. Bramwell, after investigation, reported that Dr. Diamond's treatment was correct. The case came up for decision a few days ago before Sheriff Barclay, and, in the course of his remarks, Mr. Mitchell, solicitor for Dr. Diamond, said that it was entirely owing to some dispute between Mr. Cerr, Lady Willoughby d'Eresby's factor, and the pursuer, that the doctor had had to come into Court at all. While the factor and the doctor were on friendly terms everything went smoothly, and the doctor's services were duly appreciated; but immediately after the disagreement the factor's powers, which, as his Lordship knew, were not small, were exercised in a hostile manner to the pursuer. Another doctor was called in and patronised, and the pursuer *was starved or boycotted out of the district*. The documents in process showed that while the factor and the doctor were friendly the doctor's salary was increased; but that immediately on the doctor refusing to coincide with the factor's views and exercising his own judgment, asserting there was diphtheria in the district, a great change in the attitude to the doctor took place, rendering it necessary for him to leave the locality. Mr. Henry White, the defendant's solicitor, stated that after the strong report which had been lodged he could not contend against judgment. The Sheriff said that he had no alternative but to give judgment for amount claimed, with costs. Apropos of the foregoing, on which we congratulate Dr. Diamond, we may remind our readers that, at least among the successful and fashionable members of the profession in Scotland, almost all affections of the throat are "diphtheria;" and the matter of diagnosis, at least, in Glasgow, seems of infinitely less moment than in Perthshire!

**THE LECTURESHIP ON ANATOMY, SURGEON'S HALL.**—The vacancy in the lectureship of anatomy at Surgeon's Hall occasioned by the death of Dr. Handyside, is being advertised. From the advertisement we learn that Dr. Moinet is the secretary of the school. What school? Hitherto we have been given to understand that Dr.

Stevenson Macadam is the recognised secretary of the Extra Mural School. Has Dr. Moinet started a school of his own? Considering the popularity of the University Professor and of Mr. Symington, the existing extra mural lecturer on anatomy, intending candidates should think twice before they embark in the expensive luxury of attempting to teach anatomy in Edinburgh.

**EDINBURGH ROYAL MEDICAL SOCIETY.**—The annual dinner of the Royal Medical Society of Edinburgh was held in the Waterloo Hotel on the 8th inst. About forty gentlemen were present. Mr. Dobbie, senior president, occupied the chair, while Mr. R. A. Lundie, another of the presidents, was croupier. Amongst the guests were Dr. Haldane, Professor Balfour, the Rev. Principal Rainy, the Rev. Professor Charteris, Professor MacLagan, Professor Simpson, Professor T. R. Fraser, Professor Turner, Mr. Imlach, Dr. Clouston, Dr. Byrom Bramwell, &c. In responding for "The Universities of Scotland," proposed by Mr. Lundie, Professor Turner in a speech which was listened to with attention, said that at present the examination system—not merely the class, but the degree examination system—had developed itself to such an extent that students were harassed by it to a degree which the men of the standing of the chairman's father never experienced. It had often appeared to him (Professor Turner) that the examination system had reached a pitch when too great a strain was put upon the students and the candidates for degrees. It would be well if they could alleviate the stringency of that examination system in such a way as to allow for a greater development of individual talent—to allow the really able men to feel that they might follow out their own thoughts and line of study with a greater liberty than was undoubtedly competent for them at the present time.

**THE EDINBURGH COLLEGE OF SURGEONS AND ITS FELLOWSHIP "DISTINCTION."**—That the strictures recently published on the Fellowship "distinction" are bearing good fruit is evidenced by the fact that an examiner and prominent member of the "party of progress" has resigned his examinership. The "party of delay" must surely now see the error of their ways, and that it would have been far better to have put their "house in order" in a quiet way themselves than to leave the dirty work to other hands. He must be a bold man, not to give him other qualities who after the recent exposure of the practice of awarding the Fellowship "distinction" in the medical journals and in the House of Commons, will come forward as a candidate for the honour. The root of all the evil that has now come upon the College is the well-known fact that for many years past the College has been governed by a clique. All the officials elect themselves. The council elects the president; the president elects the council who have just previously elected him; the examiners elect themselves; every examiner is prepared to examine upon anything and everything, and thus the affairs of the College are all carried out in the same happy family manner. One cannot but regret to see this happy state of things breaking up; but even the College, like all other mundane institutions, is liable to change. Change is of two kinds, retrograde and progressive. The College has now its choice and that choice must be made at once; delays are dangerous; and public opinion will not be satisfied till that change is made, and for the better.

**THE VACANT CHAIR OF MIDWIFERY AT ANDERSON'S COLLEGE.**—Since our last impression the young obstetricians of Glasgow have "quickenened," and quite a host of candidates are announced for this chair. Among them we may

mention the names of Drs. W. L. Reid, Wallace Anderson, Sloan, Shand, Robert Bell, Murdoch Cameron. In support of his claims, Dr. Reid may urge his invention of a forceps; Wallace Anderson that he has lectured—we understand, with acceptance—at the Infirmary; Sloan his connection with “the Maternity,” and his belladonna ointment for pectoral innunction; Shand a good preliminary education (which the mere fact of being a medical practitioner does not always guarantee), and some years’ close and intelligent attention to the subject. As for Dr. Robert Bell, his candidature simply excites a smile in the ranks of the profession of Glasgow, as it is calculated that during the few years he has been in practice he has been a candidate for nearly fifty different appointments, ranging from the School Board to the—well, we are not quite sure about the Principalship of the University; and as for his writings, they are of so comprehensive a nature as to range from the potato-disease to retro-flexion of the uterus as caused by constipation of the bowels! Such an Admirable Crichton ought to stagger “the Philosophers” of Anderson’s School. We don’t know what Dr. Murdoch Cameron’s claims are. We shall watch the struggle with interest. *Floreat res mulierum!*

THE REV. JOSEPH COOK ON ALCOHOL AND THE BRAIN.—The Rev. Joseph Cook is one of those American lecturers who, from strong devotion to godliness and a good fee, vouchsafe to lecture the good people of Scotland into a better and holier frame of mind. It not unfrequently happens that a good cause is much damaged by ignorant advocacy, and both in the realms of religion and science this is the fate that has attended the public appearances of this Transatlantic philanthropist (!) There is no class of men who are more alive to the evil effects of intemperance than medical men; at the same time, and from that conviction, they must deplore such *ad captandum vulgus* arguments as those advanced by the Rev. Joseph Cook in his Free Assembly Hall lecture in Edinburgh. The lecturer, we are informed, proceeded to illustrate, by pouring alcohol on the white of an egg, the effect of drinking upon the albumen in the system! and he further stated that by hardening the albuminous substances in the body *alcohol left scars on the brain and nerves which could not wash or grow out any more than scars in the skin*. In a professional journal it would be insulting to the sense of our readers to point out the groundlessness and fallaciousness of such statements and experiments. We repeat our unqualified belief in the prejudicial effects of an inordinate indulgence in alcohol; but we assert no less strongly our belief that the cause of temperance is not to be advanced by such ignorant statements as those referred to; and we heartily wish that, with Moody and Sankey, and Dr. Talmage, America would kindly keep such lecturers to herself.

MEDICAL RELIEF IN SCOTLAND.—We are pleased to notice that the question of Poor-law medical relief to Scotland has recently been brought officially under the notice of the Government. We have had occasion more than once in these pages to point out the unsatisfactory relationship of public medical officers to the authorities, and especially the uncertain tenure of their office, and the want of a superannuation allowance. These ought to be made the subject of a representation on the part of the profession in Scotland to the Government, and as the present is a most opportune time, we hope the matter will be heartily and vigorously taken up by those immediately concerned. If the profession does not move in the matter, apathy on the part of the Government cannot be wondered at. We shall be glad to give all the assistance in our power to buoy such a move

ment, believing that the interests of the profession and the public demand it.

EDINBURGH.—THE PROPOSED FEVER HOSPITAL.—On the 8th inst. the Lord Provost’s and Public Health Committee had a meeting to consider the letter of acceptance on the part of the managers of the infirmary of the offer of £16,000 on behalf of the corporation, for the central block of the old infirmary buildings, but declining to allow the western block to pass into the hands of the Town Council at so low a figure as £7,000. After a long discussion, the Committee, we believe, agreed to refer the matter *simpliciter* to the Council, a special meeting of which is to be held forthwith.

HEALTH OF EDINBURGH.—For the week ending with Saturday the 5th inst., the deaths in Edinburgh amounted to 96, and the rate of mortality was 23 per 1,000. At least 60 deaths were due to diseases of the chest, while there was only one fatal case of fever. There were five deaths from scarlatina, and ten from whooping-cough.

GLASGOW DEATH RATE.—By a very singular coincidence the Glasgow death-rate for the week ending with Saturday the 5th inst., was 23 per 1,000 per annum, the same as in the preceding week, and the corresponding week of last year.

A WELL-MERITED COMPLIMENT.—We have much pleasure in stating that at their last meeting the directors of the Glasgow Royal Infirmary unanimously elected Dr. Andrew Buchanan, Emeritus Professor of Physiology in the University, honorary consulting surgeon to that institution, a distinction well-earned by his long and honourable connection with the hospital, and the high respect in which he is held by the profession. It is understood that this is the first appointment of the kind ever made, and it is equally honourable to both parties. His old pupils dispersed throughout the world will be pleased to learn that, notwithstanding his advanced age, Dr. Buchanan’s good constitution has withstood, in a most satisfactory manner, the severe winter weather experienced in Glasgow. His mental faculties are as vigorous and clear as ever. He has lost none of his genuine appreciation of humour, and a good professional story derives an affectionate pleasure from the third generation around him, and his leisure is still occupied by the study of matters relating to the profession which he loved so well, and during his long life did so much to advance and adorn. “I am senior, sed cruda des viridisque senectus.”

ROYAL SOCIETY OF EDINBURGH.—At the seventh ordinary meeting of the Royal Society of Edinburgh of the current session, held on the 7th inst., under the Presidency of the Right Hon. Lord Moncrieff, Dr. D. J. Cunningham, Senior Demonstrator of Anatomy in the University, stated to the Society the interesting results of a series of observations he had made “On the Intrinsic Muscles of the Mammalian Foot.” The typical arrangement of these muscles, he pointed out, was found in certain of the marsupials, and the deviations from the typical arrangements found in the other mammals were of two classes—those, namely, which were to be accounted for by division of typical muscles, and those explained by the principle of fusion. Certain of these deviations clearly demonstrated the operation of a process of retrograde degeneration of muscles to suit morphological and functional alterations in the several parts.

It is announced from Calcutta that the Government has sanctioned the formation of a native army hospital corps, to be established on a footing similar to that on which the English army hospital corps is based.

## Literature.

### CANCER OF THE RECTUM: ITS PATHOLOGY, DIAGNOSIS, AND TREATMENT. (a)

THIS is a useful little work upon the subject of malignant diseases of the rectum, consisting largely of the Jacksonian Prize Essay of 1876. The author starts with the explanation that he uses the word cancer as equivalent to malignant growth, and thus sarcomata and other growths are classed as cancer. To employ the word cancer in such a signification is to return to the times when pathology was fit only for men of science and not for surgeons. The tables and the author's reasoning on the question of heredity are interesting. He shows that according to the Registrar-General's reports cancer has steadily increased from 1851 to 1876, being one in seventy-three in the former year, gradually increasing in percentage to one in forty-four in the latter. In a future edition statistics might be still more elaborated. The author puts the lowest estimate on the view that cancer is to any extent hereditary; and with him we entirely agree. A useful table would be one showing the number of children possessed by cancerous persons and whether the number of deaths among those children, from cancer is greater than one in forty-four, the percentage of deaths from cancer in the year 1876. Our tables are carried out the wrong way; we trace upwards instead of downwards, and so get confused, for it follows that every person living who has forty-five relatives may be expected to have one of those die of cancer.

The chapter on Diagnosis would be more correctly described as the recognition of cancer than diagnosis. The diagnosis of cancer may be generally sufficiently evident but cases occur in which benign diseases are mistaken for cancer, for instance we can recall the case of a medical gentleman who suffered for two years from a gradually increasing growth of the rectum. It was diagnosed to be cancer by men of reputation, and he was advised to get rid of his practice and to carry out necessary arrangements during the short time yet allotted to him. All this advice he mournfully carried out, when at the end of the second year of suffering more than a pint of matter was discharged from the rectum, and from that day he rapidly recovered. He has now a family to keep but no practice. To obviate such unfortunate mistakes as these, the chapter on diagnosis ought to include every disease which bears any resemblance to cancer, and such an explanation as shall render the recognition of one from the other simple. The treatment is gone into at length; but operative treatment by excision should be a little more carefully valued. It is an operation not to be lightly undertaken; and it is rather unfair to patients that works should suggest to inexperienced surgeons, dangerous operations without clearly pointing out the risks entailed, and the circumstances and conditions which contra-indicate an operation.

### DOMESTIC HYGIENE. (b)

THE growing needs of the people with respect to improved sanitary arrangements, both in towns and houses, have created demands for manuals in which the several readers can find information divested of technicalities, and complete enough to afford him a guide to the means of healthy existence. Of the number of books written with this end in view, none can be recommended with so much confidence as the attractive and able manual of Dr. Wilson. It contains a mass of valuable instruction on all important parts, so displayed as to receive the attention and consideration of the reader, while the practical rules for personal conduct, and the plainly worded warnings of evils to be guarded against, make the work an invaluable addition to the library of every householder. Commencing with a statistical exposition of the evil consequences to the nation of preventable diseases, the author next sketches the structural arrangements of the human body, incorporating so much physiological explanation as is necessary in the account to render it clear to the non-scientific man. The causes of

(a) "Cancer of the Rectum: its Pathology, Diagnosis, and Treatment, including a portion of the Jacksonian Prize Essay for 1876." By W. Harrison Cripps, F.R.C.S. London: J. and A. Churchill. Pp. 191. 1880.

(b) "Healthy Life and Healthy Dwellings." By George Wilson, M.A., M.D., &c. London: J. and A. Churchill. 1880.

disease and values of food and diet, are followed by directions relating to personal hygiene; the essentials of a healthy dwelling are next detailed, and the work concludes with a chapter on infectious disease. In this last section, Dr. Wilson insists on the public necessity of registration of infectious disease—a point on which he is in agreement with those who have appreciated the vast importance of the question in its bearing on public health. The volume is one that can be unhesitatingly recommended as scientifically accurate, intelligibly written, attractive to read, and elegant in appearance.

### ANTISEPTIC SURGERY. (a)

MR. MACCORMAC has done good service by collecting into a single volume an account of the debate which took place in December, 1879, and January, 1880, at St. Thomas's Hospital, on the subject of antiseptic surgery. Mr. MacCormac's own contribution is a very considerable one, the task of opening the discussion having fallen to him. The address, he then delivered, and which constitutes the initial part of the work under notice, is a most careful and praiseworthy abstract of the notable facts connected with the practice of Listerism.

An elaborate analysis of statistical details is a valuable feature of it; and historically it possesses features to give it paramount interest. The subsequent debate, in which Messrs. Bryant, Lister, Spencer Wells, Hutchinson, and many others took part, is presented in verbatim, corrected reports of the speeches delivered. Mr. MacCormac's words, when replying to the debate, will be echoed by every reader of this report of it—viz., "that this discussion is one of the most valuable contributions to surgery which has been made for some time." We may apply a very similar expression of opinion to the remaining portion of Mr. MacCormac's book, and say of it, that, as an epitome of the principles and practice of antiseptic surgery, it is, *per se*, the most valuable contribution to surgical literature recently published; and especially will it have a value for students and young practitioners who feel confusion at the contradictory statements they are continually hearing respecting the virtues or demerits of Listerism. The Antiseptic Theory, Antiseptic Materials, and Antiseptic Practice, respectively, are the heads of the work under which Mr. MacCormac further treats his subject.

The second section, "Antiseptic Materials," is particularly interesting; the various substances proposed, or employed, are described, and their virtues and shortcomings reviewed in a manner that will, we imagine, prove of considerable assistance to such as make use of the information embodied in it.

"Antiseptic Practice," as might be supposed, is a deeply interesting chapter, and it also lays claim to much completeness. The more important, typical operations are described as conducted under rigid antiseptic rules, and described clearly and well. This treatise on Antiseptic Surgery should be familiar to the more ambitious students; and we cannot recommend them a more valuable exercise than will be found in its perusal.

### CUNNINGHAM'S DISSECTOR. (b)

DR. CUNNINGHAM'S Dissector's Guide has obtained the favourable notices of students who have used the first part in prosecuting their study of practical anatomy. The objection raised to it hitherto, that it has been insufficiently explanatory, cannot be maintained against the more recent instalment of the work, which is copiously complete for all ordinary requirements.

The anatomy of the abdomen is here treated of in a bulky volume of over 300 pages, and it is creditable to its author that it is possible to say of it that it is not too long for the object in view, that, viz., of directing the student's work. That crux of the dissecting room, the peritoneum, is very clearly and elegantly described, its course and relations made clear by aid of a series of very skillfully devised and well executed drawings. The pelvic fascia, too, is much more

(a) "Antiseptic Surgery." By William MacCormac, M.A., F.R.C.S. E. & I., &c. London: Smith, Elder, and Co. 1880.

(b) "The Dissector's Guide." By D. T. Cunningham, M.D., C.M., &c. Part II.—Abdomen. Edinburgh: MacLachlan and Stewart. London: Simpkin and Co. 1880.

comprehensively explained than is frequently the case in anatomical text books. Throughout the work especial care seems to have been devoted to those points that most trouble is experienced with by students, and which teachers, unfortunately, do not always succeed in satisfactorily elucidating. The diagrams and figures throughout are excellently and clearly drawn and executed, and the book is clearly and boldly printed on good paper.

### SURGICAL LECTURES (a).

IN these Lectures, which are mostly reprinted from the medical journals, the Author dwells on various subjects which have specially engaged his attention during seven years' work as a hospital surgeon. The treatment of club-foot has at length been brought within the range of osteotomy, in otherwise incurable cases. Excision of the cuboid bone, or of a wedge-shaped portion of the tarsal arch, has proved effectual for the reduction of obstinate talipes varus; and Mr. Davy's experience, although not original, must be credited with having done much to recommend this procedure. He has also removed a wedge-shaped portion of the tarsal arch, anteriorly, in the case of talipes equinus, of nineteen years' duration; but the man having died two weeks after the operation from septicæmia, the permanent benefit that might have resulted could not be determined. Less advantage can be claimed, we think, for the treatment of spinal curvature by Davy's hammock-suspension, instead of Sayre's original method by means of the tripod. Spinal extension, judiciously regulated, is necessary to ensure some separation of the carious bodies of the vertebrae for a cure to be effected. The open treatment of wounds advocated by Mr. Davy possesses the obvious advantage of simplicity, as compared with the troublesome and expensive mystery of Listerism; and the results, in a healthy hospital, are certainly equally successful. To surgeons who have adopted the ritual of the "antiseptic system," more as an article of surgical faith than as justified by experience, the admonition of the Author is full of wisdom. "By so pointedly directing attention to the dressing of wounds, the minds of surgeons are in danger of becoming narrow; for the wound itself is but a single element in a surgical case, and in many instances the amount of suppuration is of no vital import, the bugbear pyæmia is to be combated by sanitation, only one condition of which is supplied by the dressings." "In ordinary surgical work, I question the necessity for the antiseptic system; the game is really not worth the candle."

It is impossible to conclude this notice without mentioning Davy's lever for compressing, per rectum, the iliac arteries or even the aorta, this method of controlling hemorrhage having proved most effectual in amputation at the hip-joint.

The colloquial style of these Lectures renders them pleasant reading, and the occasionally quaint expressiveness or graphic illustrations by which the Author conveys or enforces his meanings, are a relief to the dull level of ordinary discourses. The subject matter also, although not for the most part original, is yet an honest and valuable contribution to surgical literature.

### BUCK'S HYGIENE AND PUBLIC HEALTH. (b)

THE second volume of this important treatise on Hygiene, is devoted to the Hygiene of Occupation and Public Health. The first division is again sub-divided into five parts, viz., occupation, hygiene of camps, of the naval and merchant marine, of coal mines, of metal mines, from the pens of Drs. Roger S. Tracey, Charles Smart, Thomas J. Turner, and Mr. Henry C. Sheper, the editor of the *Miner's Journal* and Mr. Rosentour E. Raymond, editor of the *Engineering and Mining Journal*.

The first paper, by Dr. Tracy, is a most exhaustive one, as it enters into all the details of the special occupations in which we find disease, arising either from vapours and gases, dust, vicissitudes of weather, artificial heat, over use of certain organs as the eyes, vocal organs, constrained attitude, sedentary life, mechanical violence, &c.

The second paper will prove interesting to our volunteer medical officers, as it is written for a condition of military

service, somewhat similar to our own, whilst the marine medical officer will find in the third paper by Dr. Turner, "On the Hygiene of the Naval and Merchant Service," a useful guide for those conditions with which they have to deal.

The next sections are of special importance to those practitioners who live in our mining and coal getting districts, as they are from the pen of experienced engineers, and of great practical importance. The second part is devoted to such subjects as infant mortality, vital statistics, the adulteration of food, public nuisances, quarantine, contagious diseases, syphilis, disinfectants, village sanitary associations, and school hygiene. The papers are written by authors of standing reputation in the States.

We would direct special attention to the article on Village Sanitary Associations, for it is in such localities we find the greatest amount of ignorance, though it is there we ought to be best able to check epidemic disease, and to solve any problems in connection with sickness. We regret that this paper is not printed in pamphlet form for popular reading; we believe it would do an incalculable amount of good if the suggestion made was carried out.

We have to congratulate the publishers on the production of this work, and on securing the services of so many able men to write special articles on subjects with which they were conversant, as they have produced a guide for the sanitary student unequalled of its kind in English literature.

## Correspondence.

### HIGHER TITLES.

"Palman qui meruit ferat."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would appear from the tone of letters, articles, and a question in the House of Commons, that both the public and the profession are, to a great extent, ignorant of the meaning and significance of the higher professional titles. May I be permitted to offer a few remarks on this much vexed question?

The Doctorate of Medicine is conferred by the great majority of British universities without examination.

The Fellowship is conferred by the Royal Colleges of Physicians of London and Edinburgh without examination, and by the King and Queen's College of Ireland on similar terms.

The Fellowship of the Royal Colleges of Surgeons of England and Edinburgh is also conferred by election, and without examination. The London College also admits *all comers* to its Fellowship by examination. The Royal College of Surgeons in Ireland only confers its Fellowship by examination.

The Fellowship of either of the Colleges of Physicians and Surgeons are not professional qualifications, but are simply higher denominations, and do not confer any greater privilege than a vote on the general management of college property.

The degree of M.D. holds the same relation, except where it has been obtained without residence, and as a primary degree, as was the case in some of the northern universities some twenty years ago. In such cases it is a simple license to practitioners in Scotland, and not in England.

I, myself, consider a degree or Fellowship obtained by election, the recipient having obtained the minor degree or diploma of his College by examination, and having, for a number of years, borne an honourable name in his profession, a much higher distinction than a similar degree or diploma obtained by a six month's "grind." I think the time has come when some sweeping change should be made, and the confusion at present existing on the subject of qualifications removed.

In conclusion, allow me to point out that "the most coveted distinction, viz., the 'F.R.S.' is conferred by election," and has more weight as a higher title than either M.D., F.R.C.P., or F.R.C.S.

Yours, &c.,

WILLIAM DONOVAN.

Whitwick, March 7, 1881.

[Our correspondent is in error as to the legal validity of these higher degrees. They are as perfect titles to practise as any licenses or diplomas can be. It is true they are not usually granted except to those who are already qualified for

(a) "Surgical Lectures." By Richard Davy, F.R.C.S. London: Smith, Elder and Co. 1880.

(b) "Buck's Hygiene and Public Health." Vol. II. New York: William Wood & Co. 1880.

registration, but, if it pleased any College or University to grant its higher degree to an unqualified person, that person might claim registration, and would be, *ipso facto*, as legal a practitioner as any other. In fact, the Medical Council was obliged to refuse to register *per se* degrees, conferred *honoris causa*, because a University or College might grant such degree to a non-medical person, and might, thereby, admit him to practice without the essential education or diploma. No doubt, as our correspondent says, a higher degree granted by election to a qualified practitioner of long experience, and, bearing an honourable name, scientifically and personally, might be tolerated. But what guarantee have we that any of these desirable qualities are looked upon as essential by those who grant the degree? Is there not a danger that the £25 may cover a multitude of sins? Was it by virtue of his "honourable name" that Mr. Beaney, of Melbourne, became a Fellow of the Edinburgh College of Surgeons *in absentia*? And what is the analogy between the F.R.S., which is granted without payment to men of the most exalted scientific rank, and the F.R.C.S. Edin., which is obtainable by unknown persons at the antipodes, and paid for in hard cash?—Ed. M. P. & C.]

#### NOTE ON THE TREATMENT OF TYPHUS FEVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At present, when typhus fever prevails so widely, I venture to draw attention through your pages to a remedy which, I have reason to believe, is not as extensively used as it merits. I speak of barm, which, when I was appointed to the Cork Street Hospital, I found had been long in use in the institution. It was used whenever fever of the typhus type prevailed, and I began to order it, and I rather think more extensively than any of my predecessors.

That barm exerts a salutary influence on typhus fever I cannot doubt. On a former occasion I entered more fully into the subject than I wish to do now. I may, however, observe that under its use petechiæ rapidly change their hue from dark to red. On one occasion, too, when this type of fever prevailed far above the average, I tabulated over three hundred cases which were treated by barm, and found the mortality was under nine per cent. ; and when I add that all these cases were densely spotted, I cannot but consider the result as very satisfactory. It should be stated also that no case was excluded from this list, though several of them died within forty-eight hours of their admission to hospital.

Barm, when given in full doses, acts slightly on the bowels. I would state, in conclusion, that I have the strongest conviction typhus should be regularly treated from its commencement, not merely watched.

I remain, yours,  
HENRY KENNEDY.

#### RECOGNITION OF PROVINCIAL HOSPITALS FOR EDUCATIONAL PURPOSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to call the attention of union hospital and other provincial physicians to the fact that the new Irish University will practically have the whole medical examinations of Ireland in their grasp for the future, and that as the selfish Dublin medical element will not be quite so powerful in its management as in the recesses of their Colleges of Surgeons and Physicians, there is now a good prospect that the fair claims of provincial men to participate in medical training may at last be respected, and the recommendation of the General Council at last enforced. I will be very happy to draw up a memorial to the Senate on the subject, and I now solicit the signatures of my workhouse brethren. It is not too late, as changes will of course be made from time to time by the Senate, and it is not clear that the last touch has even as yet been given to the programme. I could adduce many reasons why every countryman ought to try and have his hospital frequented by pupils, but though I know some have no taste or ambition on this point, I yet am so convinced that

the great majority really anxious, as I am myself, that I do not think it necessary to give reasons for my view. I hope if the selfish Dublin element show their hostility, that we shall one and all know how to mark those who may do so. In my Carmichael Essay, and I hope in the *Medical Press* the whole claims we can urge will be found.

I am, &c.,

Cashel, Feb. 26.

T. LAFFAN.

[It would be a practical way of approaching the question, if our correspondent would suggest some means by which the *bona fides* of study in provincial hospitals could be ensured. There are 163 workhouse hospitals in Ireland, besides 30 county infirmaries, and numerous other hospitals which might seek recognition as centres of medical teaching. A licensing body, to grant such recognition, must be satisfied—a. that the teaching arrangements are adequate; b. that the study is likely to be genuine. What guarantees on this subject can Dr. Laffan suggest? In Dublin, the competency of an hospital to teach its pupils is liable to be tested by official inspection, and is actually tested by public opinion, neither of which means are applicable in the case of a provincial hospital.—Ed. M. P. & C.]

#### THE DUALITY OF THE CHANCRE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On Monday last, March 7th, I was examined for four hours before the Committee of the House of Commons appointed to examine as to the working of the Contagious Diseases Acts. I found that there existed in the minds of the members of that Committee, none of whom were medical men, a great amount of confusion about the term "primary venereal sores," and I was asked over and over again, "Can we not by treating the hard sore prevent the occurrence of syphilis?" My reply was, "No; when that sore appears, which is some three weeks or a month after infection, the wolf is already in the fold."

It appears that Mr. Myers and some other army surgeons are still wedded to the idea which I thought had been exploded twenty-five years and more ago by the splendid researches of Dr. Bassereau, that the "soft sore" and the initial lesion of syphilis are related or identical. Such an idea is simply untenable in the light of modern knowledge of facts, and I look upon it as quite a lamentable blot on our English medical statistics, which, indeed, makes them valueless, that the two sores should be confounded in the Army Medical Blue-Books. The soft sore has no incubation at all, for in twelve hours we can see it with the magnifying glass after inoculation. The incubation of syphilis again is usually three weeks, in my experience, and often much longer. The soft sore is always a well-marked, suppurating sore, and may be inoculated a thousand times on any healthy patient without giving him syphilis; whilst the hard sore is often a most insignificant affair, especially on women, painless in many instances; and when its secretion is inoculated on persons without syphilis, it always gives that disease. Everyone in Paris agrees with this; and in London H. Lee, B. Hill, and the *élites* agree with it. Why, then, do the army doctors keep up this confusion!

I am, Sir,

Yours obediently,

C. R. DRYSDALE, M.D.,

Physician to the Rescue Society of London.

17 Woburn Place.

March 11th.

#### THE DESIDERATUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The instrument of which the enclosed is an illustration (and which I have named "The Desideratum" for the purpose of registration), was invented by me to obviate as far as possible the awkwardness and inconvenience attendant on the eating of their meals by persons deprived of the use of either arm.

You will perceive that it is on the principle of the abacus,

being formed of a fork and cutting blade, which enables the person using it to divide at will and raise his or her food.

It can be had to suit either the right or left hand, and with or without an indentation (which acts as a tooth) on the fork edge.

Messrs. Arnold and Sons, of West Smithfield, have most intelligently carried out my design.

Your kindly allowing this instrument to become known to the profession and the public through the medium of the *Medical Press and Circular*, will much oblige,

Yours faithfully,

JOHN C. HOGAN, M.B.

Lister's Avenue, Lavender Hill, S.W.

#### THE BILL FOR NOTIFICATION OF INFECTIOUS DISEASE IN DUBLIN.

We understand that the Irish Colleges of Physicians and Surgeons have had this Bill under consideration, and, while disapproving of its provisions, have resolved to petition for its remission to a Royal Commission to inquire as to the best method of carrying out notification. This proposition, if intended to refer to the whole subject of the best means of detecting infective disease in large towns, is a good one; but if intended to refer to the application of the system to Ireland, as proposed by Mr. Gray's Bill, is extremely dangerous to the interests of the profession. The only question seriously in dispute in Ireland is whether the medical attendant should, or should not, be compelled, under legal penalty, to notify the occurrence of infectious disease to the sanitary authority. The members of the profession in Dublin, so far as they have expressed their opinions, have declared by a large majority, and in emphatic terms, that they protest against being made the unpaid sanitary detectives of the Dublin corporation, and the College of Physicians and Irish Medical Association have enunciated this opinion.

Are the Dublin physicians now going to leave it to the decision of a Royal Commission whether or not they are to be afflicted with the performance of this function? If so they would simplify matters by at once accepting the process-serving duty which Mr. Gray and the corporation kindly offer them, for it needs no great discrimination to see that the judgment of the Royal Commission will infallibly be against them. It is easy to anticipate how an insignificant knot of Dublin doctors will fare when their interests are adjudged by a number of English lawyers, upon whose minds the whole force of the partisans of compulsory notification will be brought to bear. These gentlemen will be told that the system has worked admirably in English towns—that the objection to it in Ireland is only unreasoning prejudice—and that, if they will only force it on the profession in Dublin, no difficulty or objection will, after a little be made. Naturally, not understanding any distinction between the systems of medical practice in England and Ireland, they will give judgment in favour

of compulsory notification—*cetera va sans dire*. Now it is necessary for the profession in Dublin, if they do not desire to have compulsory notification imposed on them, to take some speedy means of making their influence heard and felt. Mr. Gray's Bill is down for second reading in less than a fortnight, and, if a vigorous protest against it be not made, it will certainly pass, because, with such good prospects of adoption, it will certainly not wait for a Royal Commission. It has its origin in a Dublin organisation representing English medical opinion; it is promoted by the corporation; it is approved by the Chief Secretary, and if the profession is not alive to the imminence of the danger it will certainly become law before a month has passed, in which case the Dublin physician will find himself forced, under a £5 penalty, to serve the corporation with a notice of every case of infective disease he may see, whether his patient likes it or not—and at the munificent rate of 1s. for all the cases which turn up in the same house within a month.

Possibly the profession in Dublin may like the prospect which a few perfervid sanitarians have provided for them. We do not; and we therefore discharge the duty of again warning the physicians of Dublin.

#### THE INTERNATIONAL MEDICAL CONGRESS, 1881.

THE Reception Committee are already in a position to give a fair idea of the nature of some of the entertainments and excursions which will take place during the week of the Congress, and which will be of a most attractive character, especially to our foreign visitors. On Tuesday, August 2nd, an informal reception will be held in the afternoon at the Royal College of Physicians, which occasion, it is thought, will afford an excellent opportunity for introductions. On the evening of Wednesday, the English members will entertain their foreign *confrères* at a *conversazione* at the South Kensington Museum; the Lords Commissioners having most liberally remitted the charges for lighting usually made on these occasions. Entertainments will also be given on Tuesday and Friday, but up to this time their nature has not been definitely fixed upon. On Saturday, August 6th, there will be no business meetings later than 1 p.m., and excursions will be made to various places of interest in the neighbourhood of London. On this day the Harvey Memorial Committee purpose that the Statue of Harvey shall be unveiled at Folkestone, and, for this occasion, most liberal arrangements have been made by the South Eastern Railway Company. A special train will take between one and two hundred members of the Congress with other distinguished persons to Folkestone free of cost, where they will be received by a deputation of local authorities, and conducted to the statue, which will be unveiled. After the completion of the ceremony the Mayor and Corporation will entertain their visitors at a banquet in the Town Hall. This visit will afford our foreign colleagues an excellent opportunity of seeing an English watering-place at its best. On the same day a charming excursion has been planned by Dr. Langdon Down, who has generously invited 500 members of the Congress to a garden party at Normansfield, Hampton Wick. Dr. Down will meet his visitors at Teddington Station, and will guide them through Bushey Park to Hampton Court Palace. The party will then proceed by water to Normansfield, where a select party of Dr. Down's friends will meet them. Sir Joseph Hooker will receive a number of members the same day at Kew Gardens. On Sunday special services will be held in St. Paul's Cathedral and Westminster Abbey, at which Canon Liddon and Dean Stanley will respectively officiate.

## NOTICES TO CORRESPONDENTS.

MR. I. SUTTON should apply to the Secretary at the Royal College of Surgeons for the information.

DR. J. S.—Shortly.

DR. WARREN.—The book is in hand, and the review promised at an early date.

DR. PIERSON (Scarborough) will please receive our thanks.

DR. JOHNSON.—The action comes on in the Court of Queen's Bench this week, and will probably be decided by the time you receive the present number. It is simply another instance of the "law's delay."

STUDENS.—Ziemssen's "Cyclopaedia" cannot be obtained except by subscription for the whole series of volumes. You might, perhaps, succeed in getting the one you want at a second-hand bookseller's.

ZOEDONE.—Such has been the financial success of this enterprise that the original shares are worth more than double the amount paid for them, and now the same Company have started "The Indian Zoedone Company," for which they are to receive £25,000 for permission to manufacture and sell zoedone throughout our Indian possessions. Verily, by a happy notion, huge fortunes are made in a few months, whilst the toilers of a lifetime struggle on for a bare existence. But zoedone is a legitimate article, and we are glad to chronicle its success; its enormous consumption must have done something towards reducing that of spirituous liquors.

AN IRISH DISPENSARY EPISODE.—A correspondent sends us the following amusing incident which occurred in his district last week:—Rustic, running along the road at top speed: "Ho, doctor, what are you going to do with that mad man? He killed his wife yesterday and the day before." Doctor: "And is she dead yet?" "No," from rustic. "Then summon him."

THE USES OF PAPER.—The bronze age and the iron and glass age is likely to be followed by the paper age. Some time back there were some very remarkable exhibits of paper manufacture shown at an exhibition in Germany. At the Melbourne Exhibition, however, there is exhibited, we read, a dwelling house entirely made of paper, and furnished throughout with the same material. Even the stoves, in which large fires are kept burning daily, were also made of paper. The manufacturer of this curious construction has given banquets in his paper house, at which the table-cloths, dishes, knives and forks, and even bottles and tumblers were made of paper.

THE SUPPLY OF SEA-WATER TO LONDON.—The signature to the letter on this subject in our last was mis-spelled Bayes, it should read "John Hayes," Assoc. Memb. Inst. C.E.

IRISH GRADUATES' ASSOCIATION.—Members of this Association are reminded that the annual dinner takes place to-morrow at Willis's Rooms, St. James's, at 7 p.m., Dr. G. Paget, F.R.S., of Cambridge, in the chair. Dinner-tickets, 7s. 6d. each for members and their friends, can be obtained of Dr. Thompson, Leamington, or Dr. Daniel, 20 Cathcart Road, Kensington.

SURGICAL SOCIETY OF IRELAND.—The case of "Uterine Fibromyoma," communicated by Mr. Thornley Stoker to the Society, and published in our Journal on the 16th of February, was, by a typographical error, made to appear all through the paper as an instance of fibro-myxoma.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—This day (Wednesday) and on Friday next, at 4 p.m., Prof. W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Cetacea."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—This day, and on Friday next, at 5 p.m., Gulstonian Lectures: Dr. Coupland, "On Anaemia."

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.—This evening, at 7.45, communications from Mr. Edward Bartlett, &c.—Council Meeting.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—This evening, at 8, Mr. T. P. Bruce Warren, "On the Manufacture of Aerated Waters."

HARVEIAN SOCIETY OF LONDON.—Thursday, March 17, at 8.30 p.m., Mr. Bryant, "A Case of Gastrostomy for Cicatricial Stricture of the Oesophagus."—Dr. Gowers, "On the so-called Tendon Reflex Contractions."

ROYAL INSTITUTION.—Tuesday, March 22, at 3 p.m., Prof. Schöler, "On the Blood."

## VACANCIES.

Charing Cross Hospital.—Assistant Surgeon on the Staff. Candidates must possess the F.R.C.S. Eng. Applications to the Secretary before April 2.

Durham Union.—Medical Officer for the Eastern District. Salary, £45, with the usual extra fees. Applications to the Clerk before March 18.

Glamorgan Infirmary, Cardiff.—House Surgeon. Salary, £100, with board. Applications, under cover, to the Secretary before Mar. 29.

Hull General Infirmary.—House Surgeon. Salary, 100 guineas, with board, &c. Applications to the Chairman of the House Committee before March 21.

Kent and Canterbury Hospital.—House Surgeon. Salary commencing at £80, with board. Applications to the Secretary at Canterbury before March 25.

Manchester, St. Mary's Lying-in Hospital.—Medical Officer to visit patients at their homes. Salary, £80, with board and residence. Applications to Dr. Badford by March 18.

Stockport Infirmary.—Medical Officer to visit Out-patients. Salary commencing at £70, with board. Applications to the Hon. Sec. before March 21.

West Sussex Infirmary, Chichester.—House Surgeon and Secretary. Salary, £100, with board. Applications to the Secretary before April 9.

## APPOINTMENTS.

BRAMISH, W., M.D., L.R.C.S. Ed., reappointed Senior Physician to the Cork Fever Hospital.

BUDDS, W. T., L.K.Q.C.P.I., L.R.C.S.I., reappointed Physician to Out-patient's of the Cork Fever Hospital.

BYRNE, Dr. E. H., Physician to the High Street Dispensary, Dublin.

CAMPBELL, W., L.R.C.S. Ed., Medical Officer to the Hastings Dispensary.

COLBORNE, H., M.R.C.S.E., Medical Officer to the Hastings Dispensary.

COX, Dr. M. F., of Sligo, Physician to St. Vincent's Hospital, Dublin.

CROWE, J. W., L.K.Q.C.P.I., L.R.C.S.I., Honorary Physician to the Hartlepool Hospital.

FIELD, J. W., M.R.C.S.E., L.R.C.P. Ed., Assistant Surgeon to the Tewkesbury Hospital.

HOSKYN, D. T., M.R.C.S.E., Medical Officer for the Prestelgne District of the Knighton Union.

HOUGHTON, W. B., M.D., M.R.C.P., Lecturer on Forensic Medicine at Charing Cross Hospital.

JENKINS, J. H., L.R.C.P. Ed., M.R.C.S.E., Medical Officer for Sixth District of the Liskeard Union.

JENKINS, T. G., L.R.C.P. Ed., M.R.C.S.E., Medical Officer for the Second district and the Workhouse of the Ruthin Union.

JONES, J. F., L.F.P.S.G., L.R.C.P. Ed., Medical Officer for the Llanegryn District of the Dolgelly Union.

JONES, H. M., M.D., F.R.C.S.E., reappointed Physician to the Cork Fever Hospital.

KIRBY, T. C., L.K.Q.C.P.I., M.R.C.S.E., Consulting Physician to the North-West London Free Dispensary for Sick Children.

MOORE, T., F.R.C.S., Visiting Surgeon to the "Dreadnought" Seamen's Hospital, Greenwich, vice Davies Colley, F.R.C.S., resigned.

ARMY MEDICAL DEPARTMENT.—The following appointments were officially gazetted on Friday, March 11th:—Deputy Surgeon-General S. H. Fasson, M.D., to be Surgeon-General, vice H. Kendall, granted retired pay; Brigade Surgeon W. Stewart, M.D., to be Deputy Surgeon-General, vice S. H. Fasson, M.D.; Surgeon Major C. A. Innes, M.D., to be Brigade Surgeon, vice A. Semple, M.D., granted retired pay; Surgeon Major N. Norris to be Brigade Surgeon, vice W. Stewart, M.D.; Surgeon Major T. Y. Baker retires on temporary half-pay.

To be Surgeons, dated Feb. 5th.—S. A. Crick, M.B., J. E. Dodd, M.B., A. J. Struthers, M.B., G. E. Twiss, R. F. Adams, M.B., C. G. D. Mose, A. B. Cottell, T. Archer, M.D., S. G. Hamilton, H. J. E. Moberly, A. P. Hart, M.B., H. J. Barnes, E. H. S. Sawyer, M.B., W. G. A. Bedford, M.B., R. Jennings, M.D., S. C. B. Robinson, H. S. Parker, T. F. W. Fogarty, M.B., R. W. Ford, G. Coutts, M.B., A. Sharpe, M.D., C. L. Young, C. Reid, M.B., W. J. Baker, A. T. Sloggett, E. B. K. Elmes, H. K. Allport, M.D., E. Butt, S. Townsend, M.D., T. P. Woodhouse, J. Gibson, M.B., J. H. A. Rhodes, A. Hickman, M.D., T. C. Nugent, G. S. Lewis, L. W. Swabey, R. Haselden, E. E. R. Morse, W. J. Lyons, M.D., W. Rowney, M.D., T. E. Lucas, M.B., C. J. Addison, A. G. Kay, M.B., W. W. Pope, E. Porter, M.B., R. C. K. Laffan, C. A. P. Mitchell, M.D., G. J. Coates, M.D., G. W. H. Cook, T. B. A. Tuckey, F. A. Harris, C. B. Lewis, T. H. Parke, F. A. B. Daly, M.B., A. S. Rose, M.B., D. L. Porter, J. Batteray, M.B., J. Macnaonach, A. H. Morgan, C. H. Dixon, M.B., T. Moynihan, M. W. O'Keefe, M.D., T. J. O'Donnell, J. Osburne, H. E. R. Wolrige, R. P. Hetherington, M.B., E. C. Johnston, M.B., T. A. Dixon, W. C. T. Poole, M.B.

## Births.

COLGATE.—March 8, at Tresserras, Eastbourne, the wife of Henry Colgate, M.D., F.R.C.S., of a son.

NELIGAN.—March 8, at Denny Street, Tralee, the wife of J. W. Neligan, M.B., of a daughter.

STONEV.—March 7, at Abbeyleix, Queen's County, the wife of Hugh B. Stoney, M.B., of a daughter.

## Marriages.

CHAPMAN—CRUMP.—March 9, at St. Margaret's, Westminster, Walter Chapman, F.R.C.S. Eng., of Lower Tooting, Surrey, to Martha, widow of Albert Crump, of Forest Hill, Kent.

## Deaths.

DEMPSTER.—Feb. 27, at Duncannon, co. Waterford, James Carroll Dempster, M.D., Deputy Surgeon-General.

EARLE.—Feb. 23, at Warbeck Road, Shepherd's Bush, Frederic J. Earle, M.D., Surgeon-Major her Majesty's Bengal Army, aged 53.

FOSTER.—Feb. 26, at Park Place, Leeds, Edwin Foster, L.R.C.P.L. aged 73.

GODRICH.—March 7, at Fulham Road, S.W., of apoplexy, Francis Godrich, M.R.C.S.E., aged 65.

HADEN.—March 9, at Gordon Place, Kensington, Emma, widow of Charles Thomas Haden, M.D., in her 83th year.

HANRAHAN.—March 7, at Castletown, Queen's County, Mary, the wife of William Hanrahan, M.D.

RICHARDS.—March 7, Samuel Richards, M.D., of Bedford Square, in his 73rd year.

THORNTON.—March 4, suddenly, at his residence, Bank Lodge, Scarborough, Wm. Henry Thornton, M.D., F.R.C.S.E., J.P., aged 55.

TRUMAN.—March 2, suddenly, at New Basford, Notts, Samuel John Truman, M.R.C.S.E., aged 85.

WILLIAMS.—March 11, at Wrexham, Margaret Rinmer, wife of J. Llewellyn Williams, M.B., aged 52.

## UNIVERSITY of DURHAM.—A FIRST

EXAMINATION for the Degrees of M.R. and M.S. will commence on MONDAY, APRIL 25th, at the University College of Medicine, Newcastle-upon-Tyne. Names of intending Candidates must be forwarded to the Registrar of the College, Dr. LUKH ARMSTRONG, together with the Fee, £5, and the Schedule of the Certificates required, duly signed, not later than the 23th inst.

## OBSTETRICAL SOCIETY of LONDON.—

THE QUARTERLY EXAMINATION for MIDWIVES will be held on WEDNESDAY, APRIL 13th. Candidates should apply at the Society's Library, 291 Regent Street, W., on or before March 31st.

# The Medical Press & Circular.

## The Gulstonian Lectures

ON

### ANÆMIA,

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS,

By SIDNEY COUPLAND, M.D., F.R.C.P.,  
Physician to the Middlesex Hospital.

#### LECTURE II.—ABSTRACT.

THIS lecture was occupied with the subject of idiopathic or essential anæmia. After alluding to the earliest recognition by Addison of cases of progressive fatal anæmia in adults with no discoverable lesions beyond fatty degeneration of the heart, and referring to the cases published by Dr. Barclay in 1851, Dr. Wilks in 1857, Dr. Habershon in 1863, and Dr. King in 1871, the new departure arising out of Biermer's essay on a form of "Progressive Pernicious Anæmia usually accompanied by Fatty Degeneration of the Circulatory Passages, and secondarily by Hæmorrhages of the Skin, Retina, Brain and its Serous Membranes" was pointed out; and the rapid growth of the literature on the subject during the last decade was attributed to the impetus given by Biermer's work. At first it was thought that a new disease had been added to the nosology; but Drs. Wilks, F. Taylor, and Pye-Smith re-asserted the claims of Addison, and proved conclusively that such was not the case. It was further pointed out that the new terminology had been made to embrace not only cases of the class described by Addison, but others arising from known causes; and it was held that pernicious anæmia includes but does not comprise idiopathic anæmia. Out of 110 cases collected from various sources (probably not one-half of the whole number that had been published), 56 occurred in males, and 54 in females; the ages varied with the sexes; 59 per cent. occurring between the ages of 40 and 60 amongst the males, and 63 per cent. between 20 and 40 amongst

the females. Müller's statistics of 44 cases from Biermer's clinic showed a far larger proportion of females, viz., 35, of which number no fewer than 28 occurred between the ages of 20 and 40, a preponderance corresponding to the period of child-bearing. The onset was sometimes sudden, more often insidious, hastened or determined by direct losses of blood or other discharges, and other prodromal influences. The symptoms were fully comprised in the phrase "progressive anæmia," increasing pallor, inertia, breathlessness on exertion, and palpitation; frequently with no change in general nutrition of body, or even an excessive amount of subcutaneous fat; and in later stages, sometimes dropsical effusions. Nervous symptoms, such as neuralgia, headache, vertigo, tinnitus, and a degree of dyspnoea sometimes painful, but (so far as the lecturer knew) not ever of the type of Cheyne-Stokes respiration, in spite of the presence of cardiac degeneration with which that type of dyspnoea is often allied. Pulmonary œdema, or passive pleural effusions towards the close, liability to syncope, quick feeble action of the heart, with undulating impulse, and sometimes signs pointing to dilatation, "hæmic" bruits, excessive arterial pulsation, and sometimes jugular pulsation, with loud venous hum. In addition, hæmorrhages frequently make their appearance, and may become profuse; menorrhagia, epistaxis cerebral hæmorrhages, subcutaneous, sub-serous and sub-mucous ecchymoses, and occasionally hæmorrhagic foci in the viscera. Retinal hæmorrhages were the most frequent—met with in 30 out of 39 cases—but their appearance does not appear to imply a fatal termination, nor their absence necessitate a favourable prognosis, for out of 30 cases, eleven are said to have "recovered," and out of 9, in which there were no retinal hæmorrhages, 6 terminated fatally. Usually no enlargement of liver, spleen, or lymphatic glands; and in only a few cases has tenderness over the bones (pointing to medullary affection) been observed. In a few cases albuminuria occurs, but the urine is generally free from albumen; it is notably deficient in nitrogenous matters, and also in chlorides, but the phosphoric acid is said to be relatively increased (Edelfesen). In one of Dr. Finny's cases a notable excess of iron was found in the urine. The

remarkable and irregular pyrexia, with the occurrence of sudden exacerbations, often characterised its course, and illustrative charts were shown. This paradoxical "anæmic fever," (compared with the pyrexia of leukæmia and Hodgkin's disease) is attributed by Immermann to the retrogressive tissue-changes, for it certainly cannot be due to increased metabolism by oxidation. The duration of the disease, so far as can be gathered from its uncertain onset, was from 1 to 6 months in 32 out of 110 cases; from 6 to 12 months in 24; and from 1 to 2 years in 25. Some cases appear to have permanently recovered, e.g., Quincke's cases treated by transfusion; others relapse in a longer or shorter time after improvement or apparent recovery, and the majority end fatally. There is no clinical distinction between the cases which recover, and those which run a lethal course. Death takes place by asthenia, sometimes in coma, or in syncope, sometimes in dyspnoeal attacks, or in convulsions. The post-mortem appearances present, besides passive serous effusions, and hæmorrhages, fatty degenerations, especially of the heart.

Brief details were given of 6 cases in the Middlesex Hospital during the past 10 years; three in young women, with a history not differing from that of chlorosis, but all fatal; one, after profuse and uncontrollable uterine hæmorrhage, attributed to the anæmic condition; one in a male, æt. 43; one in a female, æt. 46 (with relapse after 14 months interval, and still under treatment), and one in a boy, æt. 7, the youngest case Dr. Coupland was aware of. These cases illustrated some of the various types of idiopathic anæmia.

The term "pernicious" has been applied in two different senses, and some confusion has arisen in consequence. Thus it had been held to imply simply a severe form of anæmia; and it had also been used in a specific sense. From a consideration of the conditions under which it is met with, it seems more rational to use it in the former sense (although we may be ignorant of the exact process by which any given anæmia becomes "pernicious.") On this view there may be simple and pernicious forms of both varieties of anæmia, the symptomatic and idiopathic; varieties destined one day to be merged into one when etiology is perfected. The prodromal conditions of these cases were then analysed, and it was shown that in 70 out of 110 cases these sufficed for the production of an anæmia, even of severe form, such conditions being bad living and food, repeated pregnancies, gastro-intestinal disturbance, hæmorrhages, malarial influences, and nervous derangements. Attempts to explain those cases in which no sufficient etiological factors existed, as well as to throw light upon the reason why an anæmia becomes pernicious, had been made by investigations into the blood, and the condition of the bone-marrow. The changes in the blood, which consisted in diminution in hæmoglobin and corpuscles, and extreme variations in the size and form of the latter, might be due either to imperfect blood formation, or increased blood destruction. The marrow changes, which were not constantly found, and had been by some attributed to the cachectic condition, and not as the source of it, were those of hyperplasia. There is no *prima facie* reason against a primary myelogenous anæmia, which would bear relations to leukæmia and pseudo-leukæmia (Hodgkin's disease and splenic anæmia); whilst in chlorosis, everything points to an idiopathic anæmia, which is dependent upon imperfect evolution of the blood.

SURGEON-MAJOR F. B. SCOTT, M.D., has been selected by Sir Frederick Roberts as the medical officer to be attached to his head-quarters staff. He held a similar appointment on the staff of Lord Chelmsford during the Zulu campaign, and subsequently accompanied the Empress Eugénie on her mournful pilgrimage to South Africa.

## Original Communications.

### VERTEBRÆ IN PROCESS OF DISINTEGRATION BY CARIES NOT NECESSARILY ACCOMPANIED BY PAIN OR BY TENDERNESS IN THE OVERLYING SOFT STRUCTURES.

By R. WILLS RICHARDSON,

Surgeon to the Adelaide Medical and Surgical Hospitals, Dublin.

It is remarkable that the absence of tenderness in the soft parts over deep-seated caries, in the bodies of vertebræ, for example, has attracted the attention of but few writers upon caries; it being by no means exceptional to meet with cases in which the bodies of two, three, or even of more vertebræ, have been destroyed by the disease, tenderness in the overlying soft parts being absent during the whole course of the demolition. I have repeatedly pressed with my fingers the skin and underlying spinous processes of vertebræ, in the bodies of which caries was progressing, and have percussed them with the rubber-ringed stethoscope ear-piece without causing pain, which these tests would almost to a certainty have caused, had the subcutaneous soft parts been inflamed.

My trials of the hot sponge test have enabled me to record my testimony in favour of Sir Benjamin Brodie's observation, that it is much more likely to cause pain in the hysterical affection of the spine than when it is the seat of caries. It is almost unnecessary to observe that the pressure and percussion tests should not be applied with a force sufficient to cause pain in uninfamed structures.

The frequent absence of tenderness from the coverings of deep-seated caries did not elude the observation of Stanley, who mentions that, "In bones that are deeply situated, caries is often accompanied by very little evidence of inflammation, either in the bone or in its investing soft parts. Thus the scrofulous caries of the spine often advances to the destruction of the bodies of many vertebræ, without tenderness in the bones or in the soft parts investing them." (a)

Such, likewise, was Nélaton's experience, who speaks of pain as a symptom of Pott's caries as follows: "I have mentioned above that dorsal pain usually precedes the deformity of the spine; it is not always thus, however. Sometimes, in effect, a gibbosity is seen to develop itself without the patient having experienced any pain." (b)

Nélaton's observation would have been more decisive, had he stated whether it included the development of tenderness by pressing the soft coverings of carious bone. I have notes of several cases of scrofulous caries of vertebræ in which the absence of tenderness in the soft structures over the diseased bones was conspicuous. This freedom from tenderness in the soft parts situated over the bodies of vertebræ more or less disintegrated by caries was demonstrated in the following cases:—

Case.—H. A. W., æt. 9, was admitted to the Adelaide Hospital with well-marked curvature of the spine, the three superior lumbar spinous processes forming a very prominent angle. A large cold abscess engaged the lower part of the right lumbar region and also corresponded to the greater portion of the dorsum of right ileum. The cartilaginous junction between this bone and the sacrum seemed healthy.

Firm pressure applied to the coverings of the projecting processes, and percussion of the latter with the rubbered ear-piece of the stethoscope, failed to cause pain whenever these trials were made.

Case.—A. M. G., æt. 2, was admitted to the Adelaide Hospital with disease of the spine. Angular curvature was well marked, the spinal process of the 10th dorsal vertebra being most prominent, having, we were informed,

(a) A Treatise on Diseases of the Bones. By Edward Stanley, F.R.S. London, 1849. P. 53.

(b) *Éléments de Pathologie Chirurgicale*. Par A. Nélaton. Deuxième Edition; Tome Deuxième. Paris, 1868. P. 183.

almost "suddenly become so" three weeks previous to her admission. She had become very thin, and the liver was enlarged.

Tenderness was sought for in the projecting and in the other portion of the spinal column by percussing moderately with the fingers and the stethoscope ear-piece, but without success.

In this case also, the disease seemed to be progressing, if there has been no inaccuracy in the statement furnished to the clinical clerk, that the "spine became very angular not many days previously."

*Case.*—M. M. H., set. 3½, was admitted to the Adelaide Hospital with angular curvature of the spine, the spinous process of 5th dorsal vertebra being most prominent. Her father stated that he observed "nothing wrong" until a fortnight before she was admitted, when she complained of backache and painful breathing, attributed to a fall off a chair a few days previously.

When admitted she had no pain. The backward projection of the 5th dorsal spinous process was accompanied by slight lateral curvature to the left. During the six weeks she remained in hospital the projecting and the other portions of the spine were tested, from time to time, for tenderness after the manner followed in the last case, but with negative results.

*Case.*—H. B., having a large psoas abscess, placed himself under my care. The spine was, I may say, almost daily examined for several months for deformity and for tenderness. At first there was no deformity, and on no occasion could I find any evidence of tenderness, when tested in the manner I have mentioned.

With regard to the psoas abscess, I allowed it to open spontaneously, as recommended by Dupuytren in his observation on the treatment of this abscess. The opening formed a little below Poupert's ligament, and gave exit to a large quantity of whey-like fluid, and many pus-floes. Eventually the sac contracted, and closed.

Mr. B.— returned to the country, and I did not see him again for many months, when he consulted me for difficulty in breathing. This was caused by a large pleuritic effusion at the right side.

In consultation with the late Dr. Stokes, it was decided that I should draw off the fluid from the pleural cavity in case its absorption did not soon commence. This, however, rapidly took place, and the paracentesis was not required. During this illness the soft parts over the spine, were free from tenderness on every trial. There was no deformity, and when Mr. B.— had recovered sufficient strength, he was permitted to return home.

Several months having expired, he called upon me, but on this occasion, with shortened stature, and strongly marked angular dorsal curvature.

The projecting spinous processes, and their coverings, as well as those of the cervical and lumbar vertebrae, were again tested, but as regards pain, with negative results.

Although the notes of this case are brief, it had a tedious history. Mr. B.— eventually died of the so-called uræmic poisoning, caused, probably, by renal "amyloid" degeneration. Let me observe that spontaneous pain should not be confounded with tenderness to pressure.

Mr. Stanley's observations upon the diagnostic value of pain in caries of the spine are of much interest, and are fully corroborated by the cases I have narrated.

"The reply of experience," he has recorded, "will be that pain in the spine is not sure evidence of disease in it; nor is the absence of pain sufficient proof of the soundness of its structures. The many acknowledged sources of tenderness in the spine forbid the conclusion, in any case, that, independently of other circumstances, it must be the effect of organic disease. And the absence of pain in the spine is no proof of the soundness of its structures, since disease is often observed running its course to destruction of the parts it has attacked without an uneasy feeling in them. But, notwithstanding its always doubtful character, pain in the spine, if persistent, limited to a small

district, and not yielding to treatment, is a symptom not to be disregarded. I have known instances of attacks of pain in the lower part of the spine confidently treated as lumbago, which proved to be the precursor of complete and permanent paraplegia, from disease in the spinal cord. And I have, also, known instances of pain in the spine treated for a long time as lumbago, which proved to be the accompaniment of destructive disease of the vertebrae."

"Pain limited to a small district of the spine, of the same character as that which belongs to disease of the vertebrae, is often the first and continuing symptom of disease in the spinal cord; and hence, the obscurity in the diagnosis of these affections is, in some cases, so great, that the treatment throughout is conducted with uncertainty, whether the disease be in the vertebrae or in the cord."

"How much caution should be observed in deciding upon the significance of pain and tenderness in the spine, even when long persistent, and fixed in a small district of it, is to be learned from cases such as I have known, where the pain in the spine of this character had been for many months treated with confidence of success, and by means wholly unsuited to the real nature of the disease, which proved to be an aneurism making its way through the bodies of the vertebrae."

"Here it will be well to advert to the not infrequent instances of scrofulous disease in the spine advanced to the stage of destruction of the softened vertebral bodies, with the accompanying angular projection of the spinous processes, but throughout unattended by a single symptom, local or constitutional, that had given warning of the existence of the disease. It has several times happened to me as it must have done to others, to be told that in a child, apparently in perfect health, the discovery had by accident been made of a projection of one of the spinous processes so marked as to permit no doubt on the point of one or more of the softened vertebral bodies being crushed, and, perhaps, wholly removed." (a)

#### STIMULANTS IN WORKHOUSES—ALCOHOLIC LIQUORS AS MEDICINES FOR THE SICK.

By NORMAN KERR, M.D., F.L.S., London.

(Continued from page 222.)

WHAT has been the result of the reduction of alcoholic stimuli on the mortality of the patients?

From one medical officer, and from one alone, has come forth the opinion that his diminishing the supply of intoxicating drinks to his pauper patients has increased the mortality. The solitary witness on this side of the question is Mr. Anderson, Medical Officer of the Walton (Liverpool) workhouse. At a late meeting of the guardians this gentleman stated that he had tried administering alcohol only to urgent and severe cases, with the result that the diminution of the stimulant had increased the death-rate. The length of time the experiment had then been tried was eight weeks. During that period in 1880 the expenditure on alcohol was £31 17s. 7d., and the deaths were 63. During the corresponding period of 1879 the expenditure was £122 7s. 8½d., with 23 deaths. In 1878 there were 22 deaths, with a charge for stimulants of £85 19s. Mr. Anderson believes also that convalescence has, from the same cause, been prolonged.

Unfortunately, though the medical officers who had previously given utterance to an opposite opinion appended to their reports the statistical data on which their opinion was based, we are not favoured with any returns from Walton. As the matter stands we have only a personal opinion. No statistics are forthcoming, so we trust that the Local Government Board—or, still better, Mr. Anderson himself, of his own accord—will produce the returns indispensable to the formation of an accurate conclusion. As the medical journals justly observe, Mr. Anderson's is so obviously a bare statement as to be without scientific value. We cannot be in a position to pronounce a sound judgment till we learn all about the nature of the fatal

(a) *Ibid.* P. 135.

cases, the atmospheric conditions, the age, occupation, and habits of the deceased, the substitutes given in lieu of alcoholic stimuli, the particular form of drink supplied to all patients for whom stimulants were ordered, the prevalent diseases and rate of mortality of the surrounding district, the materials for a critical comparison of several years' complete returns of the disease and death-rate in the house, and the actual quantities of alcoholic drink given.

The few figures we are supplied with seem to me to point to the difference in the quantity of alcohol given not being the most potent factor in the causation of the increased rate of mortality. For instance, between 1878 and 1879, there was a difference of only one death, 22 having died in the former, and 23 in the latter year. Yet the consumption of liquor was less by £36 8s. in 1878 than in 1879.

In the absence of a full official return of the mortality for some time past in Walton workhouse, I am compelled to fall back on the statement of facts by one of the guardians, given in the *Liverpool Mercury* of 27th Nov., 1880. This gentleman asserts, and he appeals to the official records for the corroboration of his statement, that from some cause or other, altogether apart from stimulants, the mortality during 1880 has been quite exceptional, bearing no comparison with 1879. In the five months ending August 31, 1880, during which time stimulants were in full use, there was 1 death in 65 per month, against 1 in 89 per month during the corresponding period of 1879. For the 4 weeks preceding Mr. Anderson's experiment, the deaths had reached 1 in 48. The guardian goes on to say that though in August and September there was much diarrhoea among the old people from the oppressive weather, though stimulants had been suddenly swept away, without any substitute having been given in their place, the mortality fell from 1 in 48 to 1 in 67 during the 4 weeks succeeding those in which £70 worth of stimulants had been used. It was during the last 4 weeks of the non-alcoholic experiment that the death-rate rose, reaching as high as 1 in 43. Such are the guardian's averments. If alcohol were withdrawn from chronic cases and no substitute given for it, I would expect an increased mortality; but I trust that all the facts will ere long be brought to light, in the hope that we may be able to eliminate all the other contributory factors, and thus learn the truth as to what influence the diminution of alcoholic drink has exercised in the interesting experiment at Walton, for the institution of which Mr. Anderson merits hearty commendation.

Meantime, it is only fair to give the following evidence relating to the earlier experience of the West Derby guardians. They report that in the year ending December, 1871, the cost of stimulants was £1,062, with an average weekly number of inmates amounting to 1,027, and the proportion of deaths 1 in 245; while in 1872, with an average weekly number of 888, the cost was £146, the mortality being reduced to 1 in 355. In the Mill Hill Road Hospital the average weekly number of inmates was 222, the cost of stimulants, £978, and the death-rate 1 in 30; while in 1872, with an average of 308 inmates, the cost was £450, the mortality being only 1 in 60. The West Derby Special Committee of 1871 reported, from the medical relief book at Walton, that in the quarter ending September, 1871, under one medical officer, with an average of 118 patients, the average supply was half a pint of ale or porter to every other patient, and three-quarters of a glass of wine or spirits to every patient every day. The deaths on this side of the house were 25. To the female side of the hospital, under another medical officer, averaging 154 patients, the supply averaged half a pint of ale or porter to every fourth patient, and a glass of wine or spirits to every sixth patient each day. The deaths on this side of the house were 16—less than one half of the male side in proportion to the population.

Whatever the soundness of Mr. Anderson's contention that the lessening of the amount of liquor increased the mortality, it cannot be denied that the evidence in favour of the converse proposition is very weighty. At Wrex-

ham, the statement embodied in the parliamentary paper already referred to, shows a slight decrease in the rate of mortality on the non-alcoholic plan. At St. George's, Hanover Square, the mortality with a minimum of alcohol is below the mean of the other metropolitan workhouses. At Barnsley the death-rate was lowered; and no one has suggested that either at South Dublin or Helston has the mortality been increased. In the Manchester workhouse hospitals Mr. Steinthal informs us that the cost of stimulants has decreased from £458 in 1876 to £204 in 1880; and that, while during the 3 years preceding the change, the deaths were 1 in 12 of the total number of inmates, during the subsequent 3 years it has been 1 in 13½.

The experience of my lamented friend, Dr. Simon Nicholls, of Longford, who was the first medical officer to give the non-alcoholic system a fair trial in a workhouse, is very striking. He adopted this plan in the poor-house at Longford for 18 years, and reported in 1866 that he had found it most successful. Dr. Nicholls informed me that while in charge of the Longford workhouse fever hospital and infirmary, from their first opening in 1841 till the cholera epidemic of 1848, he prescribed alcoholic drinks as a medicine as freely as was the usual custom in other hospitals. He then, the mortality being 94 per cent., became convinced that these beverages were injurious, and entirely discontinued their use with the most satisfactory results, the mortality from cholera at once falling to 33 per cent. In consequence of Dr. Nicholls' publication of his poor-law experience for about 2½ years, the Poor-Law Board sent over a medical inspector, who conducted a searching inquiry into the facts of the case, and confirmed the accuracy of the returns. Between 1st January, 1862, and 29th September, 1864, a period of nearly 2½ years, the mortality from fever in 115 cases was 4½ per cent., and during the year ending September, 1865, in 451 cases it was only 2½ per cent.

Mr. Brittain, of Chester, has been medical officer to the Chester Union workhouse for 39 years. For 10 years previous to 1876 the whole sum expended for stimulants was £6 17s. 6d., the highest expenditure in any one year being £1 16s. 10d., and the lowest 1s. Mr. Brittain says that he has had in the house all kinds of cases—typhus, typhoid, &c.—and his treatment has been to administer full quantities of nutritious food, beef tea, rice, milk, roast and boiled beef and mutton, &c., and when stimulants were required camphor, ammonia, and similar medicinal remedies. He adds he has never had any occasion to regret what he has done.

Dr. Collenette, of Guernsey, attended the patients of two large hospitals, one in town and the other in the country, and the paupers of a populous parish for thirty years, and never once found it necessary to prescribe either spirituous, vinous, or malt beverages.

The late Mr. Bennett, of Winterton, for forty years prescribed no alcoholic liquors; and in a serious epidemic of typhoid fever, in 500 cases he had a mortality of only 4 per cent.

During 34 years of Mr. Sleeman's tenure of office as a workhouse medical officer at Tavistock, the cost of stimulants ordered by him came to half-a-crown.

Dr. Dixon, coroner for South Oxfordshire, has held a poor-law appointment for some 30 years, and has not recommended intoxicating drink as a medicine for the last 20 years.

Many other parochial medical officers, of whom the late Dr. Morgan, of Dublin, and the late Dr. Fothergill, of Darlington, were not the least notable, extensively adopted the non-alcoholic system, and expressed the greatest satisfaction with the results.

In the ordinary treatment of the sick poor I have myself found alcoholic drinks of every kind almost wholly unnecessary; and I have the record of some 30,000 cases of disease of almost every kind that have been treated without the aid of these liquids. I have often seen such beverages, when prescribed medicinally, accelerate disease and retard convalescence, and I have occasionally, though very rarely, seen cases in which limited doses of alcohol

have been of service. The occasions on which I have thought it right to give an alcoholic drink have been so few, and the whole quantity I have prescribed has been so small, that my practice may fairly be claimed on the side of those who take strong ground against the prescription of intoxicants. At the same time I am convinced there are cases in which alcohol is a valuable remedy, a remedy, however, which ought never to be given except after due deliberation, and which ought ever to be administered in accurately defined doses with the extreme of caution, and with a renewal of the prescription when its continuance is deemed advisable.

I am not sorry that Mr. Anderson has boldly expressed his convictions, for some ardent temperance spirits have rushed to extreme conclusions for which as yet they have no warrant in facts; and I trust that this difficult question, for it is a difficult one, will now be investigated in that calm and unprejudiced frame of mind by which alone we can hope to obtain a glimpse of the truth. During the discussion of my paper at the Social Science Congress, at Liverpool, a distinguished and most estimable temperance reformer pressed me very hard for confirmation of the theory that the death-rate among the sick fell *pari passu* with the consumption of stimulants. Fortunately, though I was compelled to admit that the West Derby returns seemed at first sight to indicate a coincidence of this nature, I did not fall into the trap but took my stand on the ground that no accurate opinion could be based on any such statistics. The ages and constitutions of the inmates not only vary from day to day in the same workhouse and are ever an uncertain quantity, but no two unions follow the same practice as to the class of persons admitted. In one locality either the district medical officer or the guardians or the relieving officer, or all these three, send nearly every case of illness into the house. In another locality hardly any cases are sent in. In a third there are only cases of serious illness admitted. In short, there are no two workhouses which afford a common basis for a true comparison. It is as essential to have a thorough knowledge of the differing procedure in the various workhouses and districts as to have full particulars of the age, the sex, the disease, the history, and condition of the inmates. Only when we are able to eliminate all the other contributory factors, if in any instance this can be accomplished, will we be in a position to determine the true influence of non-alcoholic treatment on the death-rate and on the period of convalescence.

In the present state of our knowledge, I do not think we are warranted in going further than saying that the preponderance of evidence points to the probability that the absolute withdrawal or minimum prescription of alcoholic stimulants has no real influence in increasing the death-rate or protracting convalescence. For my own part I incline to the belief that, *ceteris paribus*, the mortality is likely to be lowest where stimulants, though not absolutely interdicted, are resorted to only on rare occasions, in accurately defined doses, and for a temporary purpose, the medicine being discontinued the moment the occasion for its use has passed.

At the same time, I am bound in candour to confess that we know little or nothing about the truth. The Irish returns, when analysed, clearly show this, though at first sight the mortality seems in a measure to follow the ratio of stimulation. In 20 of the unions included in the Mountmellick inquiry, in which the cost of stimulants for the year did not exceed 1s. per head on the average number relieved, the mortality was 22½ per cent. In 30 unions, in which the cost exceeded 1s. but did not exceed 5s., the mortality was 22½ per cent. In 34 unions, in which the cost exceeded 5s. per head, the mortality was 25 per cent.

That no argument in favour of the non-alcoholic or mildly alcoholic system can fairly be based on these generalizations, will be clearly seen from the following analysis of the returns. Where the deaths showed a percentage to the average number relieved of 8 per cent., the cost of stimulants per head on the average number

relieved was 2s. 7d.; where the deaths were 10½ per cent. it was 3s.; where they were 12 per cent. it was 8s. 4½d.; where they were 18 per cent. it was £1 5s. 10d. Where the deaths were 20½ per cent. the cost was 2½d. where they were 21 per cent. it was 1½d. where they were 28 per cent. it was 3½d. where the deaths were 30 per cent. the cost was 5½d. where they were 35½ per cent. it was ¾d.!!!

In one union, with an average death-rate of 12½ per cent., the expenditure was 6s. 4d. per head. In a second, with the same death-rate, the expenditure was 12s. 6d. In a third, with yet the same death-rate, the expenditure was 17s. 6d. Again, while £1 5s. 10d. yielded a death-rate of only 18 per cent., no alcohol at all gave a mortality of 19 per cent. in one workhouse (!) and 28 per cent. in another!!

English returns give similar evidence. From the West Derby Special Committee's Report of 1871 I find that the annual costs of stimulants in Marylebone, on an average of two years ending March, 1871, was at the rate of 7s. 9d., and the mortality 1 in 10½. In St. Pancras the cost was 6s. 5d., and the mortality 1 in 13; in Lambeth, 5s. 9d., and 1 in 17; in Leeds, 11½d., and 1 in 18; in Manchester, 11d., and 1 in 38; in Birmingham, 10d., and 1 in 20; in Edinburgh 5d., and 1 in 30; in Armagh, nothing, and 1 in 21½; in Lurgan there was no charge for liquor, and the mortality was 1 in 26; in Newry no strong drink was supplied, and the deaths were 1 in 38.

From the more recent returns of the second Special Committee of the West Derby Guardians, that of September, 1880, I gather that during the preceding twelve months, Marylebone, with an alcoholic expenditure per head of 6s. 1d., had almost the same death-rate as Walton, with an expenditure 3½ times as great, viz., £1 1s. 7d. The deaths in Walton were 1 in 3'86, and in Marylebone 1 in 3'83. Sunderland, with an expenditure of only 2½d. per head, had a death-rate of 1 in 4'87, while the Isle of Thanet, with an expenditure of 11s. 9d., had no more deaths than 1 in 4'79. In other words, there is little difference in the mortality, though the latter union spent fifty-six times as large a sum in intoxicating drink as the former! Sheffield, spending 2s. 7½d. per head has a death-rate of 1 in 3'06, while Glasgow, spending 4s. per head, has a death-rate of 1 in 3'07, or nearly identical. Liverpool, spending 5s. 5d., has 1 death in 2'37, a much higher rate of mortality than Paddington (1 in 2'37 against 1 in 3'36) spending nearly four times as much.

Scotland has equally contradictory and bewildering testimony. In 1877 the poorhouse of St. Cuthbert, Edinburgh, spending only 2½d. per head on alcohol, had a death-rate of 27'85 per cent., while Peebles, though spending £3 13s. 10½d. per head, had a death-rate of but 22'4 per cent. That is to say, though spending 352 times as much on alcohol as the former, it had some 5 per cent. less mortality!! Moray, with an expenditure of 3s. per head, as against the £3 13s. 10½d. of Peebles, had the same death-rate, viz., 22'4 per cent. The Abbey, Paisley, while paying more than five times as much for stimulants as Morayshire—16s. 2d. against 3s.—had a mortality of only one-fourth of the rate of the latter.

I was deeply grieved some time ago on reading the report of a statement publicly made by an excellent abstinence medical officer, for whom I have a high regard. This gentleman presented an abstract of his parochial cases treated without alcohol, and compared his own results with those of his predecessor, who prescribed alcohol, showing a considerable decrease in the death-rate under the non-alcoholic regime. A more mature experience will prove that all such comparisons are valueless, and very apt to be misleading, and that no trustworthy conclusions can be drawn from them. I have already pointed out that we must eliminate all the other factors contributing to the mortality, and demonstrate that the age, sex, disease, occupation, surrounding circumstances, and state of health of the groups compared fairly correspond before we are justified in the claim to have formed a sound judgment. We ought to be very careful not to rush to a rash

and unwarranted conclusion ourselves, and we cannot be too chary in making assertions that cannot be borne out by a searching and critical scrutiny. In the present absence of definite information, no one is in a position to dogmatise on the subject. All we can do meanwhile is to endeavour to add to the mass of reliable statistical data now rapidly accumulating, in the hope that the time may one day arrive when sufficient thoroughly sifted material will have been gathered to enable vital statisticians to establish unimpeachable general laws. That time is not yet.

(To be continued.)

### SURGICAL DRESSINGS IN PRIVATE PRACTICE.

By WM. BERRY, M.R.C.S. Eng., L.R.C.P. & S. Ed.,  
Hon. Surgeon Royal Albert Edward Infirm., Wigan.

WHILST Listerism in surgical practice is *sub judice*, perhaps more especially in private practice, owing to the want of time, help, and appliances, on the part of the general practitioner, it is well, perhaps, that some safe, simple and effective mode of dressing can be employed.

The examples from hospital practice afforded by Mr. Sampson Gamgee, of Birmingham, are certainly satisfactory, and will, I think, commend his mode of treatment to the busy practitioner. His *dictum* of rest, drainage and pressure, if duly carried out will save much time and trouble, and show results comparable with the antiseptic method.

I have endeavoured through the small means at my disposal in private practice, to carry out this plan, using absorbent wool as dry dressing, proper means of drainage, and firm and even bandaging, so far am admirably satisfied with the result.

The absorbent wool, which can be obtained either in bulk or in pads, is an excellent material for carrying out this mode of treatment. When applied to a wound it forms a nice soft covering, takes up any discharges which may escape, and allows the parts to be undisturbed till the dressings are saturated and uncomfortable. If the discharges be foetid and unhealthy, the wool can be made antiseptic by means of terebinte, salicylic, carbolic, or boracic acid.

Dressings of this material are easily carried and applied, they need not be disturbed for some days, unless the thermometer indicates some disturbance of the system or the dressings become saturated, then the covering should be removed, the wound cleansed, and a renewal of fresh dressings made.

In large wounds, and in chronic abscesses, it is always better to insert a drainage tube, so as to allow of the free escape of fluids which may collect, then a sufficient covering or pad of absorbent wool, firmly and evenly bandaged on with an ordinary roller, will constitute a light and compact dressing, which may remain undisturbed till one of the conditions mentioned above necessitates a change.

I would here mention the importance that should be attached to the indications of the thermometer in all surgical cases, for long before either pulse, tongue, facial expression or pain in the part show any disturbance, the thermometric rise will indicate something wrong, then the dressings should at once be removed and the wound examined.

Mr. Gamgee in his admirable little work on the "Treatment of Wounds," says at page 10, "A glance at the thermometric chart at the head of the bed is frequently sufficient to assure the surgeon of the progress of a case, without his addressing a single question to nurse or patient."

In busy private practice and in colliery cases, it is a great advantage for the surgeon to be able to apply a neat, efficient, and safe dressing, which will not take up too much of his time or require frequent change, also where the dressings can be removed and renewed expeditiously.

In the mode of treatment recommended therefore, we have everything that could be desired.

Messrs. Southall Brothers, of Birmingham, have introduced to the notice of the profession pads for surgical dressings, made from absorbent wool folded in gauze or thin muslin, at the suggestion of Mr. Sampson Gamgee. These pads are very neat, compact, and serviceable; they suit well the purposes for which they are intended, and occupy little space, and being very light are easily carried.

In midwifery cases also we can have pads made in like manner, which are very useful and more comfortable than the ordinary diaper, they are readily burned when saturated, and can be made antiseptic by any of the known agents. The sanitary towel also for use during the menstrual period is extremely serviceable, and saves washing, the cost is the *only* drawback.

In concluding these remarks, the following notes of a case of herniotomy in private practice, will illustrate the advantages of the mode of dressing advocated above.

August 6th, 1880.—Mrs. H., *æt.* 40, mother of a large family, of spare habit of body yet tolerably healthy; had suffered for a couple of years from a hernia, which she readily reduced when it gave pain; she wore no truss or support, and whilst running a short distance, the hernial protrusion descended and gave her great pain. She was obliged to take a cab and return home. I was sent for and saw her about three hours after the descent of the hernia had taken place, and found her lying on her back with the knees drawn up, and suffering excruciating pain, there was a swelling in Scarpa's triangle the size of an egg, and very hard, I tried for half an hour to reduce it, but failed. I gave 20 minims of laudanum every two hours, and ordered warm fomentations.

I saw her again at 9 p.m., accompanied by my friend Dr. Tatham, who kindly administered chloroform for me, we both tried taxis, but failed. I now cut down on the tumour, carefully dividing the tissues till the sac was reached, the constriction could not be relieved without opening the sac, which was carefully done, and gut relieved. The knuckle of bowel was very much congested, especially as it had only been strangulated for so short a time. The edges of the wound were approximated, and three sutures of silver wire inserted, the blood sponged from the skin, and a cotton wool pad and bandage applied.

7th.—Not quite so sick as she was directly after the operation, and had passed a pretty good night. Pulse 102. Temp. 98.4. Tongue clean and moist.

9 p.m.—Pulse 102; temp. 99; feels pretty comfortable, but sick now and again. To have nothing but milk diet and ice to suck.

8th, morning.—Pulse 90; temp. 98; passed a pretty good night, sickness passing off.

Evening.—Pulse 90; temp. 99.

9th, morning.—Pulse 90; temp. 99; sickness abated, but feels soreness about the wound. To have pil. morphia (gr.  $\frac{1}{2}$ ) every 4 hours. Dressing removed, pad just soiled with a serous fluid; wound looks very healthy. A fresh pad applied.

Evening.—Pulse 108; temp. 102.2; more pain, feels tired and restless; to have morphia pill every two hours.

10th, morning.—Pulse 96; temp. 100.8; had passed a restless night. Removed the dressings, and found edges of wound congested and hard. Removed middle suture and a little serous discharge escaped. A bread poultice moderately warm, was applied.

9 p.m.—Pulse 90; temp. 99.2; feels somewhat better.

11th, morning.—Pulse 90; temp. 98.4; tongue, clean and moist, wound looks better, still congested and opening up; the skin for a circumference of two inches around wound is red and almost erysipelatous-looking. She had passed a tolerably good night. Dry lint and wool over wound.

Evening.—Pulse 96; temp. 100.2.

12th, morning.—Pulse 90; temp. 99. Had passed

a good night, wound opening up, redness of skin disappearing, a good deal of soreness, sutures removed.

Evening.—Pulse 90; temp. 99.

13th, morning.—Pulse 90; temp. 98.4. Bowels moved pretty freely and without pain, feels much better. To discontinue pills of morphia; wound looks well, but granulating from bottom.

Evening.—Pulse 90; temp. 98.4. She now progressed, the pulse and temperature remaining normal from this date; the wound gradually closing by granulations.

The wound took till the 14th of September before it was completely healed over, but previous to this she was able to get up, and get from one room to the other.

This case fully shows the importance of the daily thermometric observations, it was not until the evening of the third day that we had any evidence of the wound going wrong, and although the redness extended around the wound for some little distance, I am inclined to think that the cause of this was the force employed in taxis, and the lesson learned is two-fold, namely, (1) Do not employ too much force in trying to reduce a strangulated hernia in a healthy and strong subject; (2) Operate early, do not wait for symptoms of strangulation to set in; if you have the history of sudden strangulation, with great pain and vomiting, and taxis fails after being carefully employed, operate at once.

## Clinical Records.

### ROTUNDA HOSPITAL, DUBLIN.

*Case of Myxomatous Tumour springing from Lip of Os Uteri in a Patient at Full Term of Pregnancy—Amputation of Lip of Os Uteri Four Days before Labour set in—Subsequent Inflammation of Knee-Joint—Recovery.*

Under the care of Dr. LOMBE ATTHILL, M.D., Master of the Hospital.

Reported by Mr. E. GORDON HULL.

E. K., set. 38, was admitted into the Rotunda Hospital on the 1st November, 1880. She stated that she was then nearly at the end of the ninth month of her eleventh pregnancy, and that she had always enjoyed excellent health till in the eighth week of her present, when she noticed a copious viscid mucoid discharge to escape constantly from the vagina; this discharge soon became sanguineous. At about the end of the fourth month of pregnancy while at stool, a large mass suddenly protruded from the vulvæ. Copious hæmorrhage followed; and she became faint. On lying down the mass receded into the vagina, and the hæmorrhage ceased; but ever since, on making any exertion the mass was liable to protrude, and she was seldom free from a sanguineous discharge. Being under the impression that she was suffering only from a "bearing down of the womb," she did not for a long time consult anyone, but at length sought admission into hospital, on the recommendation of Dr. Heffernan, whom she had consulted in the country.

On admission, a large soft mass was found filling the vagina; its surface was nodulated and uneven, and bled freely on being touched; it sprang from the posterior lip of the os uteri to which it was attached by a short and wide pedicle. It could be extruded from the vagina by the voluntary efforts of the patient, and presented the ordinary appearance of a mass of epithelioma; and the opinion that the growth was of a malignant nature was strengthened by the very fetid character of the discharge. As the woman was within a few days of her confinement, a serious question arose as to the best course to adopt; but as the mass from its size would seriously impede labour, Dr. Atthill decided that its removal held out the greatest hope of lessening both the risk of hæmorrhage to which the patient was liable, and the danger of septicæmia to which she was exposed. The operation was accordingly performed on Friday, November 6th, by means of the écraseur, the wire of which was passed up as high as possible so as to include the portion of the posterior lip of the os uteri from which the tumour sprang, the patient being under the influence

of chloroform. No hæmorrhage followed; some fever, however, supervened, and the temperature rose on the next morning to 102 deg. Fahr., and as there was much nausea she was ordered an effervescent alkaline mixture.

On Sunday morning, the 8th, labour pains set in; these were of a very lingering inefficient character. The membranes did not rupture until 8 a.m. on Monday morning at which time the os was still not half dilated. Warm baths were ordered with the view of relaxing the os; and on Tuesday morning at 1 a.m., barely four days after the operation, she was delivered of a male child, which, however, only lived fourteen hours. Neither during the labour nor subsequently did any hæmorrhage occur.

The patient went on favourably till the 14th, when she complained of pain in the sole of the left foot; this pain seemed to travel upwards, and finally became located in the left knee-joint.

On the 16th the following note was made:—Temperature 101 deg., pulse 108. Knee-joint swollen and tender, but not much so unless it is moved. The veins on the external surface of the leg and knee-joint are prominent and turgid, while immediately to the outside of the patella there is a dark red spot about an inch in length by half an inch broad. Neither the foot nor the leg are swollen.

On the 17th four leeches were applied, two to each side of the knee, and the joint was continuously poulticed. This relieved her greatly, and on the next day she only complained of the knee being stiff.

November 30th.—Knee enlarged and cedematous-looking, superficial veins of thigh enlarged. There was one very painful spot corresponding to the upper margin of the tibia internally. Two leeches ordered to be applied and poultices as before.

December 9th.—The knee is now nearly same size as other. There is little pain, and the patient can stand on it; Friction with a stimulating liniment is being used. The patient complains of a feeling of chilliness with shivering, followed by a hot stage, then perspiration about 5 p.m. every evening, the temperature running up to 105 deg. and pulse to 130. Ordered quinine sulph. gr. 10. to be taken at 2 p.m.; this was repeated for three days, when the attacks subsided; but they recurred again on the quinine being omitted. Her recovery was very tedious, but she was able to return home on the 23rd December, the knee being still very stiff and occasionally painful.

A microscopic examination of the tumour was subsequently made by Dr. Reuben Harvey and Dr. E. MacDowel Cosgrave, who report "that the greater portion of the tumour presented the characters of a myxoma and in no part was there anything characteristic of malignancy."

Dr. Atthill in commenting on this case pointed out that a segment of the lip of the cervix uteri more than an inch in length and half an inch in depth was removed by the écraseur, and this within forty-eight hours of the occurrence of labour, and yet no hæmorrhage followed; his reason for removing so large a portion of the cervix being his belief that the tumour was of a malignant nature, the attack from which she subsequently suffered, though evidently of septic origin, was of a very unusual nature. When the pain in the foot set in, followed by inflammation of the knee, pyæmia was dreaded, but the attack proved to be synovitis; while, when nearly convalescent, repeated attacks of intermittent fever of a severe character occurred which greatly retarded her recovery.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MARCH 2, 1881.

Dr. MATTHEWS DUNCAN, President, in the Chair.

#### INTERSTITIAL FIBROID CAUSING RETROFLEXION.

Dr. GODSON showed, for Dr. J. Dewar, a specimen of interstitial fibroid. The patient was aged 43, a widow, sterile. Three years ago, Dr. Dewar attended her for retroflexion. She wore a Hodge's pessary with advantage for some time, then it began to give pain, and had to be removed. About a year after she had an acute attack of

pelvic peritonitis, which left the uterus fixed. She died rather suddenly from a second attack of peritonitis. The specimen showed a small fibroid in the anterior wall of the body of the uterus. The fundus was retroflexed, pointing downwards very markedly.

The PRESIDENT then delivered his  
INAUGURAL ADDRESS.

DR. BARNES ON

SO-CALLED "MISSED LABOUR," WITH CASE IN ILLUSTRATION.

The author starts by stating that the term "missed labour" proposed by Oldham was not justified by the facts of Oldham's case, which proved on autopsy to have been one of extra-uterine gestation. Discussing other cases of presumed missed labour accepting the arguments of Stoltz and Müller, the author affirms that no authentic example of missed labour—this term being taken to mean the prolonged retention for an indefinite time in utero of a fœtus living at term—is yet known. He cites examples of the retention of the ovum which had perished in utero at a pre-viable age for some time, and notably until the arrival of the natural term of gestation. He relates a case which came under his own care. A lady, æt. 39, had borne three still-born children, the last of them five years ago, before consulting Dr. Veitch at Penang in December, 1872. Pregnancy dated from early in November preceding. The usual signs of pregnancy were manifested, she verified quickening, up to the seventh month she felt movements of the child. About the eighth month after a slight accident a show of blood came. Three weeks later another bleeding occurred, but no labour pains. Eleven months after the presumed date of conception she came to England. There was an impression that she might be suffering from fibroids of the uterus. She came under Dr. Barnes's care in December, 1873. Under chloroform, the cervix uteri having been dilated by laminaria tents, he felt what he took to be the interior surface of the uterus, the sound passed six inches. In January, 1874, some coloured discharges went on. Pieces of bone which turned out to be bits of the spinal column passed by vagina. After dilatation by tents, more bones were removed by fingers and forceps. In February this manœuvre was repeated, and by craniotomy-forceps the remaining parts of a fœtus which appeared to have reached the eighth or ninth month of gestation, were extracted. Her health then improved, the discharges became less offensive, and the uterus gradually shrank as in ordinary involution, but more slowly, until it reached the common conditions of the non-pregnant state, and the patient perfectly recovered. The author submits that this is a clear instance of the retention of a fœtus dying in utero at a viable stage for some months after the normal term of gestation had been reached; and that in this sense the term, missed labour, may apply. He cites the cases of Dr. M'Clintock and Dr. Hall Davis as corroborative.

Mr. SPENCER WELLS, who had seen the patient, asked if the case might not be explained on the assumption that the pregnancy was what had been called by some interstitial or mural, in which the ovum is arrested where the Fallopian tube passes through the uterine wall. He remembered that some attention had been given to this view at the patient's bedside, and thought that the subsequent history was quite consistent with this view. It was strengthened by a case he saw last year. A lady, who believed she was in the fifth month of pregnancy, was reduced to a state of extreme danger by constant pain and vomiting. Eminent men had said she could not be pregnant, because the cervical canal admitted the finger, and the sound could be moved freely to a depth of nearly five inches. Mural pregnancy was diagnosed, and ergotine was injected into the substance of the cervix uteri. Severe pains followed, and the expulsion of the fœtus, with perfect recovery.

Dr. ROPER thought that a reasonable explanation of these cases of so-called missed labour might be given from a point of view hitherto unnoted. He believed that most of them were originally uterine gestations, which, during their course became partially or wholly extra-uterine, in consequence of a degree of rupture of the uterus from external injury, or spontaneous giving way through degeneration of the uterine structures. The fœtus did not escape entirely, but to such a degree that ultimately a cyst was formed outside the uterus, the fœtus being partly within and partly without. The first symptoms were those of pain, coinci-

dent with some accident; and the pains of labour were always equivocal. The fœtus at this time died, the pain subsided; then followed the history common to all: fetid discharge, putrilage and bones. When an autopsy had been made, an aperture had been found connecting the cavities of the uterus and the cyst. The rigidity of the cervix in these cases was of interest, as illustrating uterine polarity. The fundus being injured, fundal polarity was arrested, while cervical polarity remained in full force.

Dr. GERVIS, in corroboration of Mr. Spencer Wells' suggestion, mentioned a case of extra-uterine pregnancy, in which, very unexpectedly, about the fifth month, delivery occurred, *per vias naturales*. The practitioner in attendance on introducing his hand found a distinct cavity toward the left angle of the fundus, in which evidently the fœtus had lodged. He also referred to cases in which, when delivery was due, a few ineffective pains occurred; but delivery did not occur till three or four weeks later. He mentioned a typical case in which this occurred in successive pregnancies, with the result that instrumental aid was necessary; and the child was each time born dead. At her fifth confinement, the effort of Nature was supplemented at the ninth month, and a living healthy child born. In the sixth pregnancy, there was again protracted gestation, and a still-born child.

#### ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MARCH 7TH, 1881.

THOS. ARNOLD ROGERS, President, in the Chair.

#### TUMOURS OF THE UPPER AND LOWER JAWS.

MR. CHAS. MACNAMARA exhibited a patient from whom he had removed a sarcomatous tumour of the upper jaw, and read notes of the case. The patient, a married woman, æt. 51, was admitted into the Westminster Hospital on January 29th. She had first noticed a swelling of the right upper jaw about fourteen months before; at first it caused little inconvenience, but during the last three months she had suffered severely from neuralgic pain in the right side of the face. The tumour occupied the maxillary process of the right superior maxillary bone; it did not extend back to the soft palate nor project into the nasal or orbital fossæ, and there was no enlargement of the neighbouring lymphatic glands. On February 5th, Mr. Macnamara removed it by making an incision through the upper lip, along the right ala nasi and across the cheek of the malar bone; the alveolar process was then divided to the right of the symphysis with a Hey's saw, together with the nasal process of the superior maxillæ and the malar bone, completing the separation of the tumour with the bone forceps. The patient made a rapid recovery. Mr. Macnamara showed a cast taken by Dr. Walker before the operation, and also some sections of the tumour, which proved to be an osteosarcoma, under the microscope.

Mr. BUTLIN called attention to the presence in these sections of some small rounded or oval bodies composed of calcareous matter; they were homogeneous, highly refractive and marked with slight parallel lines concentrically arranged. So far as he was aware, these bodies had only been observed in three other cases; these were all tumours of the lower jaw and all occurred in young people.

Mr. CHAS. TOMES said he had noticed the small calcareous bodies spoken of by Mr. Butlin on, at least, two previous occasions in tumours of the mouth and was not aware of their great rarity. One was a case of great hypertrophy of the gums and the other was an ordinary fibroid epulis. He was much struck with their close resemblance to the bodies called calco-spherites, which were apt to form whenever salts of lime were precipitated in the presence of organic matter.

Mr. CHARTERS WHITE afterwards read a paper on  
THE HISTOLOGY OF THE GUSTATORY ORGANS OF THE TONGUE,

In which he gave an interesting description of the remarkable bodies known as the gustatory or taste bulbs, which are found on the base of the tongue, especially in the vicinity of the papillæ circumvallatæ. The paper, which

was in the main a *resumé* of Prof. Eugelman's article published in vol. iii. of "Stricker's Histology," was illustrated by diagrams and by some beautiful microscopical specimens prepared by Mr. White.

A discussion ensued, in which Messrs. Stocken, Weiss, Coleman, Hutchinson, Ibbitson, and others took part. Mr. White having replied, the meeting was adjourned.

## Translations.

### THE TRAUMATIC CURE OF PANNUS. (a)

Translated by ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

CORNEAL infiltrations are common, whether consequent on old and ill-cared for granular affections, or on interstitial keratitis. They are symptoms of a scrofulous temperament, on which, according to some authors, hereditary syphilis has been grafted. However this may be, whether the opacity be called granular pannus or profound diffuse infiltration, the patient is none the less blind, and, therefore, during many years numerous methods of restoring transparency of the cornea have been proposed. Besides collyria and ointments without number invented *ad hoc*, the most diverse surgical operations have been employed (peritomy, syndectomy, sclerotomy, iridectomy, &c.). Blenorrhagic inflammation too has had, and still has warm partisans, and its defenders have been able to convince the most sceptical by bringing forward the most convincing proofs of its utility (Warlomont, Hanion, Brière, Panas, &c.) each of these operations (I consider purulent inoculation as such) gives clear and precise indications which way, according to the nature of the pannus, its thickness, &c. It should be remembered, however, that a mode of treatment which in one case might prove highly beneficial, might in another prove quite the reverse. I do not therefore bring forward the mode of treatment proposed by me as a universal panacea. The operative proceeding is very simple, but the results are none the less surprising.

Very rapidly, and in the course of a few days, the cornea becomes again transparent. Sometimes this transparency occurs after the first operation, and is perfect; sometimes there remains some *cloudings*, some interstitial traces; a new traumatism is then necessary, and new illumination is produced. In some cases this must be repeated three or four times in order to obtain a satisfactory result. The two most general traumatisms which have been hitherto practised are canthoplasty (enlargement of the palpebral clefts) and strabotomy. It is, of course, clearly understood that the latter has been practised only when the eye affected was strabismic, as is frequently the case. As to canthoplasty, I will at once answer an objection which may be made, when the granular eyelids are narrow and consequently rub their hard wounding asperities against the globe of the eye, it is the general custom to free the external commissure in such a manner as to give freer play to the eyelids. This is recommended in most ophthalmological treatises. Canthoplasty is not, however, advised, except in those cases where there is really rubbing. To extend canthoplasty from this to all cases of pannus is doubtless a step, but one which I believe I have been successful in making. I practise canthoplasty only as a traumatism, and of all traumatisms it is the most simple, the least painful, and the most rapidly performed. From an æsthetic point of view even it is advisable, for a slight enlargement of the palpebral cleft is pleasing rather than otherwise to the sight.

How have I been led to form this opinion? The three following cases, of which I will abridge the account, led me to do so.

Mademoiselle N., æt. 18, came to me December, 1880. There was convergent strabismus of the right eye, of which she wished to be freed on any terms. This strabismus dated from early infancy. She had lost the sight of this eye. The cornea was covered by a complete pannus, with vascular development, especially on the upper third. On turning back the eyelids vestiges of old granulations could be clearly perceived, and cicatricial traces occupied the superior portion of the tarsal cartilage, while here and there were gelatiniform infiltrations of the conjunctiva. The granular affection had

first shown itself two years before, but the right eye only was affected. The pannus developed rapidly, but for more than a year had remained stationary. The young girl troubled herself little about the sight of this eye, as she had frequently been told that the cure, if possible, would be long and tedious. I operated at once for strabismus, and the operation was perfectly successful. A few days later I was much surprised to find that the cornea was rapidly clearing (almost visibly), and the granular tissue becoming re-absorbed without further treatment. I have since lost sight of this patient.

Some days later Edward J., æt. 11, was brought to me. He was suffering from convergent strabismus of the right eye. A large leucoma occupied the whole extent of the pupillary opening. This leucoma was consequent on ill-cared ulcerous keratitis (metallic deposits in centre of leucoma). Tenotomy was practised, and eight days later the leucoma had diminished by one-half. All peripheral infiltration had disappeared. There now remained the central metallic spot which was indelible.

About the same time I attended Madame D., who suffered from old granulations and double pannus. She underwent double canthoplasty, with Gaillard's sutures to remedy the trichiasis. The cornea cleared rapidly and the granulations soon disappeared.

While these three cases were still fresh in my memory, I went round with the class of Professor Panas, who showed me several patients suffering from granular pannus who had been cured by canthoplasty aided by redressment.

M. Panas then explained to the surrounding pupils his ideas on revulsive traumatism, and recalled that in 1876 he had cured, by double tenotomy, a young girl suffering from interstitial keratitis. The priority belongs, therefore, to this eminent professor. As for me, I only claim the merit of deducing from three closely observed cases (without having heard M. Panas' opinion on the subject) a mode of treatment which I have since successfully applied on more than fifteen occasions, and to be the first to impart these facts to my professional brethren in order to persuade them to practise the treatment which I have found so successful.

M. Dehenne then quotes three other cases in which almost complete restoration of the corneal transparency followed upon operations for strabotomy or canthoplasty.

In the discussion which followed the reading of M. Dehenne's communication the following remarks were made by M. Richelot, junior.

M. Dehenne's communication appears to me to be extremely interesting, particularly as his is the first public account of the mode of action of traumatism. According to M. Dehenne the surgical action being brought to bear on any given point of the periphery of the cornea causes disappearance of the pannus. But is it traumatism alone which produces this result? May not the suppression of rubbing have something to do with it. In tenotomy might not the suppression of some conjunctival vessels be concerned in the cure.

M. Dehenne.—In those cases observed by me there was no rubbing, or if there was it was very slight indeed. I remarked this carefully. As to the section of conjunctival vessels, I do not think it can have any effect towards cure. In strabotomy, but few vessels are sectioned, and these few are generally beyond the zone of the pannus.

M. Perrin.—Has there been any relapse?

M. Dehenne.—None up to the present, and some of these operations were performed more than a year ago.

M. Mathelin.—Theoretically, does M. Dehenne make any difference between traumatism as produced by him and sclerotomy, for example, which has been highly praised as a means of restoring transparency to the panniform cornea?

M. Dehenne.—Theoretically, I make no difference, practically, a very great difference between the two methods. Sclerotomy is a critical surgical operation, as are also iridectomy, lyndectomy, &c. I, however, recommend a simple easy operation which anyone can practise, without aid, without chloroform, &c. A snip of the scissors, a suture, and all is over.

At the meeting of the Academy of Sciences in Paris on March 12th, the Boudet prizes of 6,000 francs (£240) was awarded to Professor Lister, for his application of M. Pasteur's researches to the improvement of the art of healing.

(a) A paper read before the Medico-Physical Society of Paris by M. Dehenne.

## The Mineral Waters of Europe.

### THE "MEDICAL PRESS" ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, &c.

WITH

### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P.Lond.,

Lecturer on Materia Medica and Therapeutics at the London  
Hospital, Physician to the Hospital for Diseases of the  
Throat, &c.

(Continued from page 228.)

We have for the first time noticed in the Vichy waters the undoubted presence of lithia, but only in very minute quantities, not anything like the quantity found in the Carlsbad springs. We have preferred marking this down in our analysis as "a trace," because to anything approaching an accurate determination of this base it would be necessary to operate upon very large quantities of the waters, particularly when occurring in small fractions of a grain per gallon. We have, however, we believe, detected lithia in every one of the Vichy waters examined, but in very unimportant quantities. Some of the Vichy waters are procured from artificial borings, these are Vaisse, Saint Yorre, and Larbaud. We have selected for examination those which spring naturally from the Vichy basin. Some of the waters, such as Puits Carré, are only used for baths. Sulphuretted hydrogen is given as one of the gaseous products of these waters, but any trace which they might have contained must have become oxidised, as there is not the slightest indication of that body in the bottled specimens. They, in fact, contain no alkaline sulphides, and therefore, cannot be considered in the light of sulphurated waters. Hauterive is said to emit the odour of rotten eggs when it issues from the spring. This is one reason that we examined it. No doubt this is all correct, but we never use them in this country as a sulphurated water. It is probable such waters merely owe their odour to a little gas—not to sulphides.

We may now say a few words about the direct uses of those examined. Hopital is said to be the least exciting. Hopital water is said to be, by the local medical men "difficult of digestion." We presume it causes nausea and sickness if used freely. The "Grand-Grille" and "Mesdames" are recommended in such a case, as they are supposed to be more ferruginous. They seem to be the favourites. The Celestines springs were those generally patronised by gouty patients. The Hauterive water is gradually replacing the Celestines, and seems to agree with most stomachs.

The Vichy waters all contain arsenic, but in such small quantities that the term arsenical waters will hardly apply. They do not contain a maximum pharmacopoeial dose of arsenic ( $As_2 O_3$ ) in a gallon of water.

The most important is Grand Grille, so-called, we believe, from the appearance of the rails originally surrounding the spring.

### Vichy Grand Grille.

It contains per gallon—

Bicarbonate of sodium . . . . .	294·80
Bicarbonate of potash . . . . .	21·64
Carbonate of magnesium . . . . .	18·62
Carbonate of strontium . . . . .	19·01
Carbonate of calcium . . . . .	26·68
Ferrous carbonate . . . . .	·30
Carbonate of manganese, trace	
Sulphate of sodium . . . . .	18·12
Phosphate of sodium . . . . .	8·00
Arsenic . . . . .	·09
Boracic acid, trace	
Chloride of lithium, trace	
Chloride of sodium . . . . .	32·82
Organic matters, trace	
Silica . . . . .	4·00

Total solids per gallon . . . . . 444·08

### Skeleton Analysis of half-a-pint (10 ounces fluid).

Solids.	Antacids.	Salines.	Purgatives.
27· $\frac{1}{2}$ grains.	24 grains.	2 grains.	1 grain.

The Grand Grille waters are strongly and permanently alkaline even in the cold. It seems to be fairly free from albumenoid ammonia.

The free carbonic acid was not determined, although this and the other Vichy waters retain it with considerable tenacity.

### Hauterive.

Bicarbonate of sodium . . . . .	300 grs. per gall.
Bicarbonate of potassium . . . . .	12·08
Carbonate of magnesium . . . . .	32·03
Carbonate of strontium . . . . .	·19
Carbonate of calcium . . . . .	27·62
Carbonate of protox. iron . . . . .	1·08
Carbonate of manganese, trace	
Sulphate of soda . . . . .	18·60
Phosphate of soda . . . . .	3·00
Arsenic . . . . .	·08
Boracic acid, trace	
Chloride of lithium, trace	
Chloride of sodium . . . . .	34·15
Silica . . . . .	4·43
Organic matter, trace	

433·26

Free carbonic acid not determined.

### Skeleton Analysis of half-a-pint (10 ounces fluid).

Solids.	Antacids.	Purgatives.	Salines.
27 grains.	23· $\frac{1}{2}$ grains.	1 grain	2 grains.

The Hauterive waters are strongly and permanently alkaline. They are stated to contain a larger proportion of free carbonic acid gas than the other waters of Vichy; but it is absurd to give in a bottle-water any estimation of carbonic acid gas, as it will always be a varying quantity. We have already drawn attention to the fact that the Vichy waters seem, from their composition, to retain the gas with great tenacity; therefore, they are all good waters for bottling.

A FATAL mistake was lately made in a chemist's shop in Lincoln, by the administration of liquid ammonia in a draught in mistake for water.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, MARCH 23, 1881.

## SANITARY ASSURANCE.

THE newly-created Association for Sanitary Assurance has vigorously commenced the campaign on which it enters in coming before the public, and it may be hoped that in view of the abundant reasons that exist to give it a *locus standi*, it will energetically continue its efforts to improve the conditions under which the ordinary householder lives. There are, in every town and village in the kingdom, dwellings utterly unfitted for human habitation; and even in the more pretentious quarters of suburban elegance, the average Londoner pays a heavy rent for a house which, in a sanitary sense, is wholly inadequate to the requirements of healthy living. By a series of fortuitous accidents it may, and often does, happen that it is some time ere the actual danger of the situation reveals itself, and the occupants for a more or less considerable period escape the consequences of imperfect sanitary arrangements. Sooner or later, however, these make themselves felt, but in the majority of instances even then they are not attributed to the real cause, but set down to this or that occurrence; to reasons which frequently bear absolutely no relation to the outbreak. The explanation of this is to be found in the habit by which people have become accustomed to accept tenancy in any house as the landlord provides it for them, and also in the inability of the ordinary householder to judge for himself how far his dwelling is built on scientific principles. It is to be said, however, that a general and considerable feeling is being excited in the public mind, in respect to the preventible nature of many of the diseases which are encouraged by insufficient sanitary measures,

and with it there has arisen a strong desire to do that which shall assist them in the future to avoid the dangers with which they may else be surrounded. But as we have said, ignorance of the essentials to be observed bars the way to securing this advance, and hence there remained nothing but reliance on the builder's good faith until the Sanitary Assurance Association stepped in to fill the gap that presented. This Society provides for the inspection of any building desired, by skilled officials; and these latter will, when required, draw up a report of whatever place they may be directed to examine, describing its actual sanitary condition, the alterations necessary to make it sanitariously perfect, and an estimate of the probable cost such alterations should involve. That such advice as a report of this kind would convey, is imperatively called for in respect of the vast majority of houses was rendered abundantly clear by Prof. De Chaumont in a lecture delivered at the London Institution on March 15, under the auspices of the Sanitary Assurance Association. He described how, out of an annual mortality of 700,000 in the United Kingdom, 170,000 deaths occurred from disease of the respiratory organs, consumption being chargeable with 70,000; 33,000 died from diarrhoea; 11,000 from typhoid; 25,000 from scarlet fever; and from diphtheria, 3,500. A careful examination of these figures in relation with the little that is known of the etiology of the diseases named, will reveal the fact that, roughly speaking, about one-third of the total annual mortality of the country is due to causes which are subject to prevention, and even complete suppression. In another way we can see equally certainly the direct connection that exists between sanitation and a low death-rate. Ten per cent. of the deaths annually recorded are registered as due to phthisis, and this number, considerable though it is, is yet capable of favourable comparison with what was the case many years since. As improved systems of drainage, and wiser sanitary arrangements have replaced the older and inefficient modes; as that is, districts have become drier and freer from the unhealthy accompaniments of damp ill-drained regions, so there has been apparent a corresponding decrease in the amount and intensity of the actual phthisical diseases. The improvement has been especially marked in connection with this class of complaints, and particularly has it been noted that dryness of soil is that which notably has influence on them, since other classes of diseases do not seem so directly amenable to the influence exerted through this medium. There can be no doubt, however, that as observation is more widely extended, and more minutely directed, it will result in bringing to light an innumerable set of relations between the commoner affections and the unsanitary environment in which they are contracted. In very few houses, for instance—even in those that in appearance and value claim to rank as high-class dwellings, are the arrangements for securing in every room a free and sufficient interchange of gases, enough to maintain the atmosphere within at a healthy standard. And yet it is difficult to over-estimate the important bearing exercised by this one factor on the bodily condition. When once or twice submitted to the vitiating effects of a poison-charged atmosphere, serious ill-effects are not perhaps produced; but when it comes to be the daily experience, when each evening spent at home

means existence for 4 or 5 hours out of the twenty-four in a poisoned chamber, through the absence of proper ventilation, then is it to be wondered at that after a time the effects begin to appear, the functions become disordered because the nervous system is influenced, and sooner or later it becomes necessary to seek advice, and undergo active treatment. It is a familiar fact, however, that this rarely or never terminates till the advice is taken, "go away," and then not because the treatment has brought about such a result, but because of the recuperative powers of the untainted country air. The aim to be striven after in arranging every room in a house, ought to be to secure as nearly as possible agreement between the air within and without. Other provisions for warming the in-current are, of course, necessary, and must be made. Some time, no doubt, every house will be perfectly ventilated, and seeing at how little cost it can be kept so, summer and winter. There is nothing outrageous in the demand of the sanitarian that all houses built in future shall be so arranged. The Sanitary Association can render material help in this direction, both by pointing out to its members the defects in houses on which reports are requested previously to their being purchased or hired, and also by acquainting the ordinary public in lectures, &c., of the necessity for pure air, and the comparatively inexpensive way in which it is to be secured in every house. Perhaps next to the main drainage system of a dwelling, the question of the air breathed within it most directly influences the well-being or the opposite of those living in it. Though we are in the habit of associating zymotics with specific principles, yet exhaustive analysis of the grounds of belief lead to the assumption that the air is primarily the agent of infection, since if it were not fitted to be the temporary abiding place of infectious germs, these would not be transmitted by it. Whether, however, we can hopefully anticipate at any very near period that the widespread adoption of sanitary measures at home will lead to the universal improvement of matters without, and thus to a reduction of epidemics apart from the reduction of their virulence in any particular quarter, is perhaps open to question. In any case, the Sanitary Assurance Association is well calculated to assist in the attainment of so desirable a condition of things, and we may well wish for it a great and general response to the appeal made through it for better sanitation.

#### THE INDIAN MEDICAL SERVICE.

FOR thirty advertised vacancies in the Indian Medical Service, thirty-seven candidates are said to have presented themselves at the competitive examination recently held at Burlington House, of whom only twenty-two obtained the thousand marks required as the minimum for success. Of the successful men, a large proportion would appear to be natives of India, the minority to be made up by "white candidates," regarding whose professional status, some remarks made are, by no means, flattering. Contrast we so sad a state of things with conditions in bygone times, when under the *régime* of the "East India Company," an appointment as assistant surgeon was so highly valued as to be looked upon as equal to a "writer-ship" in the Civil Service; or even in those more recent,

when entry into the Indian Medical Service was eagerly sought by some of the best students of our colleges; then let us inquire whence so great a change as we have indicated? There is every reason to believe that much, if not the whole of this great falling off, is due to the changes in position, and prospects caused by the orders of the Government of India, dated 3rd January, 1880. No doubt in this service, as in all others, it is impossible that conditions stand still; changes become necessary to meet those taking place throughout all branches of the public service. Nevertheless, confidence becomes very naturally impaired when changes made involve destruction and withdrawal of advantages formerly held; and further, when they convey the expression that they have been introduced through the instrumentality of those who, in the first instance, have chiefly benefited by them. In many respects there are serious disadvantages in a system by which one branch of a service is brought into competition with another and similar branch. It were far better to have all upon precisely the same footing as regards qualifications, position, pay, promotion, and retirement. In such a happy family, strife and contention would, theoretically, find no place; nor would concessions, made to one, have to be demanded as of right by the others. But as some little time may yet elapse before the advent of that millennium, and, meanwhile, the need for highly qualified men throughout India is great, the authorities charged with the interests of our great dependency will, no doubt, once again take into their consideration, the means most likely to attain that end. As to native Indians as *army* surgeons, accounts have reached us which give little encouragement to hope that they are likely to be ever ready to share with regiments to which they are attached, the fatigues and risks inseparable from field service. As to the same class of persons in charge of civil stations, accounts have also reached us by which we are led to doubt very much whether, in all respects, they are fitted by their early training, and constitutional *diathesis* for such a position; and we have reason to know that in some instances, at least, families of British residents at certain small stations where no English medical officer or practitioner resided have, as a result, suffered too to use a mild term, may be called the very greatest inconvenience. The evil here indicated threatens rapidly to increase under the operation of the orders already referred to. Public agitation of grievances is, at all times, an uncongenial measure to have recourse to. We trust, however, that certain evils, present and prospective, being pointed out as resulting from official regulations but recently brought into force, those evils may be removed, or, at any rate, brought down to a minimum without unnecessary delay.

#### BACTERIAL LIFE UNDER DIFFICULTIES.

WE desire to direct attention to a series of interesting experiments lately made by Mr. F. Hatton, for the purpose of ascertaining the nature of the action exerted by various gases on the life and propagation of bacteria; furthermore, what influence bacteria have on the percentage composition of the gases. The bacteria were obtained by shaking together fresh meat and distilled water, filtering

and exposing the solution to the action of air for twenty-four or more hours. This, at all times, ensures a bountiful crop of bacteria. A small flask half-filled with mercury, and then filled up with the bacteria solution, was inverted over a mercury trough. A given volume of gas was then passed up in the usual way, and the whole removed from the trough. Daily examinations of the liquid were made as to the condition of the bacteria; samples being removed by a piece of bent-glass tubing, having an india-rubber joint. In all cases after a week or fourteen days, a portion of the gas was pumped out by means of a Sprengel pump, and analysed, Temperature being kept pretty constant. Atmospheric air was first introduced, and the bacteria thrived well. A large absorption of oxygen, however, took place, and was not replaced by carbonic anhydride. In a second experiment, 20 per cent. of the oxygen disappeared, and was replaced by 17 per cent. of carbonic anhydride. Pure hydrogen was introduced, and after fourteen days had no effect on the bacteria, although 0.34 per cent. of carbonic anhydride was produced. Pure oxygen, after ten days, was converted into carbonic anhydride, 29.98 per cent.; oxygen, 70.02 per cent. Nitrogen was next tried, and in fourteen days was split up into carbonic anhydride, carbonic oxide, hydrogen and nitrogen. With all the gases used, however, the bacteria lived and flourished. Cyanogen was next passed into the meat solution, and it became gradually converted into a thick black fluid. On the fifth day only a few living bacteria were discovered, but on the sixth day an increase took place, and on the twelfth day they were once more comparatively numerous. On the fifteenth day the gas was analysed, and found to contain cyanogen, 5.35; carbonic anhydride, 57.39; oxygen, 2.24; nitrogen, 34.79 per cent. This experiment was repeated, and yielded similar results. It appears, therefore, that cyanogen is very fatal to bacteria so long as it exists as cyanogen, but so soon as decomposition, into ammonic oxalate, &c., takes place, the bacteria revive. This revival is promoted and facilitated by sunlight. Sulphurous anhydride was tried, the bacteria lived during the whole fifteen days, and the gas was changed into carbonic anhydride, nitrogen, and sulphurous oxide. Similar results were obtained from nitrous oxide, nitric oxide, mixtures of hydrogen and oxygen, solutions of urea, and phosphate of potash. In all these cases the bacteria were apparently unaffected, although various proportions of carbonic anhydride, oxygen and nitrogen, were evolved. Experiments were also made with acetylene, salicylic acid, strychnine (10 per cent.) morphine, narcotine, and brucine, but none of these substances had any perceptible effect on the vitality of the bacteria. On the other hand, phenol, alcohol, spongy iron, and potassium permanganate, exerted a very destructive effect on bacterial life. Crace Calvert had previously shown that bacteria can live in strong carbonic acid, and, in short, in almost anything. It is not a little surprising to find these remarkable organisms not only living, but flourishing in such gases as sulphurous oxide, carbonic anhydride and oxide, all highly poisonous and irrespirable by animals. As Professor Frankland observed a question of considerable importance arises out of the experiments narrated as to whether the germs of infectious diseases are not similarly

endowed with a power of resistance to ordinary influences.

We look with some degree of curiosity for Dr. Tidy's opinion of Mr. Hatton's experiments, and wonder whether this chemist, after having seen that bacteria withstands the action of cyanogen, sulphurous acid, and other deleterious gases, he will adhere to his statement that a run of a mile or two of sewage contaminated water, will ensure the destruction of any amount of bacteria, cause organisms, most tenacious of life, by endosmosis to burst their protoplasmic envelope, and commit a sort of "happy despatch" for the special security of human beings in general. The idea is too preposterous to be entertained for a moment.

## Notes on Current Topics.

### University Degrees to Women.

THE movement in favour of admitting women to equal rights with men in respect of University distinctions, progresses in a manner that cannot but prove satisfactory to such as approve the principles involved. In addition to the recent triumphs achieved by the advocates of female education at Cambridge, an almost equally considerable concession has been made during the past week by the University of St. Andrews. The Senatus of this corporation having been petitioned from numerous sources on the subject, have agreed to grant separate courses of University instruction to women as soon as a sufficient sum of money is raised for the purpose. As an equivalent to graduation in Arts, the Senatus recommend that candidates should, pending the settlement of the necessary arrangement, undergo the examination for the L.A. diploma, in which precisely the same papers are set as for the M.A. degree. The University is quite prepared to pursue the whole path of reform in this direction, and if the response made to the encouragement already offered is at all promising, there is every prospect that it will lead to the ultimate abolition of all sex restrictions upon the Arts and Science examinations of the University. A committee of professors has been appointed to superintend the development of the scheme, and full information concerning it is to be obtained from the Committee on the University Education of Women, St. Andrews.

### Herb Poisoning at Plymouth.

In a letter to *The Standard*, of March 18th, a correspondent describes the circumstances attending the death of a Greek seaman, and the serious illness of several other sailors at Plymouth recently, owing to the incautious eating of a water-herb found growing under Staddon Heights. The effects produced on those who ate the plant were those of an intense irritant poison, and are ascribed by *The Standard's* correspondent as due to the *Conium maculatum*, and *Ceanothe crocata*, the latter being that which proved fatal in the case mentioned. He further reports that it is not the only instance on record—a boat's crew of H.M.S. *Wellington* having, at the same spot, dug out and eaten what they regarded as wild celery. Eight of the men were ill afterwards, and two died from

poisoning. And, similarly, a few months ago, five sailors died from the effects produced by eating a herb found at Falmouth. A very proper suggestion is made, that steps should be taken to prevent the future occurrence of such lamentable accidents; and this end may, perhaps, be best attained by following the recommendation contained in the letter—viz., to provide Custom House officers with printed regulations for distribution among sailors, warning them against the danger of employing as food the plants they may find in the neighbourhood of landing; and, further, each consul should expose conspicuously in his office directions of the same nature. The matter is one of sufficient importance to merit attention.

#### Guy's Hospital.

It is assumed that the difficulty at Guy's Hospital is now virtually terminated in favour of the medical staff, by the publication of a series of regulations bearing on the nursing arrangements, to be observed in future. These virtually concede the principal demands originally made by the physicians and surgeons; and they provide, further, for the proper limitation of the authority and duties of the head of the nursing department. A lady nurse is to have charge of each ward, and to have under her direction two head nurses; and special provision is made for retaining the services of the nurses in the wards to which they are appointed, thus removing the highly objectionable feature of frequent changes, against which there has been a very justifiable outcry from the first occurrence of the differences. Another improvement is, that at the end of twelve months' service as probationers, candidates for the post of nurse will be required to exhibit a certificate, signed not only by the matron, but also by the medical officers; this plan is well calculated to maintain a proper degree of constant anxiety, on the part of probationers, to merit the approval of those best able to judge of their efficiency. The matron will henceforth be denominated by this, her proper title, and resign the name of superintendent, by which Dr. Steele will continue to be known. These rules, late in the day though they are, will be welcomed by everyone who has grieved to witness the deplorable injury done to Guy's by the late dissensions; and it is to be hoped there may arise nothing further to renew the protracted notoriety to which it has been so unfortunately exposed.

#### Sanitation in Oxford.

THE question of Oxford's sanitary condition, brought prominently into notice by the recent occurrence of preventable fevers in it, has led to a discussion in Convocation, provoked by the following decree proposed last week:—"That the delegates of lodging houses be authorised to make arrangements for a general inspection of licensed lodging houses in the present year; and that the curators of the University chest be empowered to pay such sums for the purpose as the delegates may think necessary." Opposition was made by Mr. Ogle, of Lincoln College, on the ground that the decree failed to define the extent of inspection or the sum to be spent; and he substituted the proposition that the matter should be deferred until the statute for appointing a controller of lodging houses should be brought into operation. This will strike everyone acquainted with the provisions existing in regard to Uni-

versity lodging houses in Oxford, as a peculiar reason for deferring sanitary precautions. Every house in which undergraduates hire rooms is subject to the licence of the 'delegates for licensing lodging houses,' and the power entrusted to them of depriving any householder of his or her licence, is in itself sufficient to enable them to demand perfect sanitary arrangements as a condition of being privileged to receive University men as lodgers. Dr. Acland supported the decree, and urged that since £200,000 had been recently expended on the main drainage of Oxford, the University, in the face of recent criticism, should adopt every means to ensure ample provisions against the risk of disease to which undergraduates were submitted. The decree ultimately passed without a division.

#### Gross Falsifications of Catechu and Saffron.

M. JOSSART (Holland) has met with a sample of catechu containing 60 to 65 per cent. of ferric carbonate. M. Crispo (Gand) has examined a sample of "fine Spanish saffron," sold to the pastrycooks and housewives of that place. It consisted of barium sulphate, 50 parts; water, 16; vegetable filaments of unknown origin, 13; and glucose, tincture of saffron, and other substances, 21.

#### The Surgical Aid Society.

A BETTER example of the questionable trading spirit that governs the charity of the Surgical Aid Society could scarcely be afforded than a case brought to the notice of the sitting magistrate at the Guildhall last week. A poor woman, whose husband had long been a sufferer from rheumatics, and required a surgical appliance, appealed for help from the poor-box of the Court. She stated that the cost of the instrument was fifty shillings, and before she could obtain it from the Society she was told by the secretary that she must procure ten letters, of the value of five shillings each. After many days labour, and weary walks about London, she had only secured seven letters; but the last three were too much for her, and her health and strength had broken down under the strain to obtain them. She was therefore driven to appeal to the Court for help. The worthy magistrate, in his goodness of heart, took compassion upon the poor woman; but whilst expressing some misgiving as to the appropriation of a sovereign from the poor-box, he remarked that in his opinion it was a parody on charity to require each applicant for relief to bring the full value of the appliance in letters before it could be had. But such are the hard rules of the Society, and similar cases of hardship are continually brought to our notice, and the sooner the managers of the Society take the matter into their serious consideration, the better for the reputation of the Surgical Aid.

We are glad to know that the committee of subscribers organised to effect a reform in the mode of administering relief had demanded a special meeting for the consideration of the question, and that it is intended to move the following resolutions, and which, we hope, will meet with hearty support:—

That the present mode of administering relief by the Society, compelling applicants in many cases to undertake a harassing and injurious canvass for letters, is a system which ought to be amended.

That one letter of recommendation should entitle the applicant to relief, subject to a favourable report from the Surgeon, and to a due regard to the claims of other applicants.

#### An Extra-Sensitive Thermometer.

PROFESSOR DUFOUR, of Paris, has devised a small thermometer, so sensitive that it will denote by a deflection of the index needle of nearly two inches the entrance of a person in the room where it is placed. The apparatus consists of a short bent tube, carrying at one end a bulb, which is coated externally with lamp-black. The tube is partially filled in the lower part of its bend with mercury, and is balanced on a steel knife-blade, exactly like the beam of a scale. Above the knife edge extends an index needle, which moves across a graduated arc, as the bent-tube swings. Beneath hangs a rod, to which is attached a small weight, to balance the needle, so as to make it point to zero on the arc. When the temperature rises, be it ever so slightly, the heat, being absorbed by the lamp-black, dilates the air in the bulb, and drives the mercury to one side. The centre of gravity of the apparatus being displaced, the bent tube is put out of level, and the needle will immediately turn towards the right. When, on the contrary, the temperature decreases, the needle will point towards the left.

#### The Health of Ireland.

DURING the quarter ended 31st December last, there was registered in Ireland a birth-rate of 20·7—a death-rate of 16·7 per 1,000.

In England last quarter, the birth-rate was 32·3, and the death-rate 19·6 per 1,000.

The birth-rate in Ireland is under the average of the quarter of previous 5 years.

The death-rate is also below average to the extent of 0·3 per 1,000. In fact, making allowances for the deficient registration in former years, it is one of the lowest death-rates on record for this period of the year. This low death-rate points to a distinct improvement in the public health, which, no doubt, is dependent upon the clemency of the weather and the plentiful harvest. It must not, however, be forgotten that the birth-rate was below the average, and as the mortality among young children is higher than at more advanced ages, a low birth-rate naturally results in a somewhat diminished death-rate.

The death-rate registered in Ireland during the quarter was 16·7 per 1,000, against an average of 17·0 for the corresponding quarter of the five years.

The death-rate in Leinster was 20·0, in Munster 18·2, in Ulster 15·2, and in Connaught 12·3.

The county death-rates range from 10·5 in Leitrim to 29·1 in Dublin.

In Leinster the total deaths are 330 (4·9 per cent.) below the average. The deaths were below the average in all the counties except Dublin.

In Munster the deaths are 141 (2·3 per cent.) above the average.

In Ulster the total deaths are 773 (9·9 per cent.) below average.

In Connaught the deaths are 241 (8·7 per cent.) below average.

The returns for the fourth quarter of 1880 point, on the whole, to an improved state of the public health, the death-rate being lower than it had been for the corresponding quarter of the previous two years, although there are good grounds for believing that registration is more complete now than it was in either of those years. It appears, however, that the deaths from the principal zymotic diseases, although showing a decrease on the preceding quarter, bear a higher ratio to the total number of deaths than in any other quarter during the past two years. This is not owing to any substantial increase in the death-rate from zymotic diseases, which is 49·7 per 100,000, against 55·7, 57·4, and 57·4 respectively for the first three quarters of the year, and compared with 46·5, and 46·2 for the corresponding quarter of 1878 and 1879. The most noticeable feature in the returns is the diminution of small-pox, the deaths from which have fallen to 17, the lowest quarterly number recorded for three years.

The Registrars' notes appended to this Report point out many interesting facts regarding the prevalence of disease. Scarlatina is specially referred to by 44 registrars, whooping-cough by 37. Fever has been as usual widely distributed, and unfortunately more fatal than usual.

#### Mr. Dodson and the Anti-Vaccinators.

THE attempt last year of Mr. Dodson, the President of the English Poor-Law Board, to gratify the anti-vaccination fanatics by making a law to prevent any of them being prosecuted more than once for a breach of the Vaccination Law, will be in the minds of our readers. The effect of his proposed measure would have been to enable anyone to purchase exemption from punishment by a payment of 40s., and to establish a *nidus* for small-pox dissemination on these easy terms; but Mr. Dodson was defeated by public opinion, and forced to abandon his Bill. This year he, it would seem, is attempting to produce the same effect, by a different means and without the sanction of Parliament; for it has been stated that the Oldham Board of Guardians have recently been instructed by the Local Government Board to use their own discretion as regards the prosecution of persons who have been summoned more than once for refusing to have their children vaccinated; and that accordingly the Oldham authorities have determined, in the case of a number of persistent anti-vaccinators, not to summon a parent more than twice for each infraction of the law. We hope that the medical members of the House of Commons will not allow this method of dispensing with the law to pass unchallenged. Should they do so, there will be dozens of boards of guardians willing to follow the example of the Oldham Board—if only to save themselves money and trouble.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population were—Brighton 15, Bradford 18, Sunderland 19, Hull 20, Edinburgh 20, Nottingham 20, Bristol 20, Portsmouth 21, Birmingham 21, Leicester 22, Salford 22, London 22, Sheffield 23, Wolverhampton 23, Plymouth 24, Glasgow 24, Newcastle-on-Tyne 25, Norwich 26, Oldham 26, Liverpool 26, Leeds 26, Manchester 28, and Dublin 35 per 1,000.

### The International Medical Congress.

We learn that the Council of the Royal College of Surgeons in Ireland, at their meeting on Thursday last, voted a grant of twenty-five guineas towards the expenses of the approaching meeting of the Congress in London. Preparations are being vigorously pushed forward by the Executive Committee, and the arrangements are now beginning to take a more definite form.

The Inaugural Address by Sir James Paget, the President-elect of the Congress, will be given in St. James's Great Hall, which has already been engaged for the purpose, on Wednesday morning, August 3rd. The following mornings will be devoted to the business of the various sections, while the afternoons (with the exception of Saturday afternoon, which will be left free for garden parties, excursions, &c.), will be occupied by the general meetings of the Congress, at which four addresses will be given by distinguished men of four nationalities. Three gentlemen have already promised to give these addresses: Professor Huxley probably on "The Connection of General Science and Medicine;" Prof. Volkmann, of Halle, on "Modern Surgery;" and Dr. Billings, of Washington, on "Medical Literature." The fourth address, to be given by a distinguished Frenchman, has not as yet been finally arranged. The meetings of the various sections will be held in rooms at Burlington House, courteously placed at the disposal of the committee by the University of London, the various Learned Societies, and the Royal Academy of Arts. This, however, not providing the required amount of accommodation, the committee have engaged Willis's Rooms for the occasion, and four of the sections will hold their meetings there.

Since the list of names published in November last, a large number of our foreign colleagues have definitely announced that they will come to the meeting, and there seems every prospect of the attendance from abroad being a full one. Meanwhile, depending on the number of names appearing as officially connected with the Congress, and on the subscription-list, together with the number of gentlemen from abroad who have positively stated their intention to attend, a certain estimate of one thousand members may be made, and it seems not unreasonable to assume that at least double that number will attend.

The Reception Committee are busily engaged, and have decided upon giving an evening reception at South Kensington, and perhaps a second in the Albert Hall; but at present the state of the subscription-list does not warrant them in making the arrangements definite. The Lord Mayor purposes entertaining members of the Congress at dinner at the Mansion House, on August 4.

THE Bill to prohibit experiments on animals, which was introduced into the New York Legislature during the present session, and referred in both branches to the Committee on Public Health, was reported adversely on Feb. 18th by the Assembly Committee, and the report agreed to by the Assembly. This, it is presumed, will finish the business for the present session. The Bill was the same with that introduced last year, and which met with a similar fate.

### The International Medical and Sanitary Exhibition.

THE arrangements for this exhibition are progressing so satisfactorily that it promises to be the most important sanitary exhibition hitherto organised in this country. Applications for space are now being rapidly sent in, as the 31st inst. is the last day fixed by the Committee for receiving them. Up to March 15th applications for 984 feet had been received by the Committee. The certificates of merit which are to be given will be valuable awards to the public and to the successful exhibitors, on account of the high character of the list of jurors, which already includes, among many others, the following:—*Medical Section*.—Christopher Heath, F.R.C.S., Wm. S. Playfair, M.D., Charles Higgins, F.R.C.S., Chas. S. Tomes, F.R.S., Prof. John Marshall, F.R.S., Dr. Robert Farquharson, M.P., the President of the Pharmaceutical Society, C. H. Golding-Bird, F.R.C.S., Lionel Beale, F.R.S., W. B. Carpenter, C.B., F.R.S., J. S. Bristowe, M.D., Major Duncan, R.A., Surgeon-General Longmore, C.B., E. H. Sieveking, M.D., &c. *Sanitary Section*.—Sir Joseph Fayrer, K.C.S.I., M.D., F.R.S., Geo. Aitchison, F.R.S., B.A., Edward C. Robins, F.S.A., J. Roger Smith, F.R.I.B.A., F. J. Moutat, M.D., Alfred Waterhouse, A.R.A., Captain Douglas Galton, C.B., F.R.S., Ernest Hart, M.R.C.S., Professor Corfield, Wm. Eassie, C. E. Rogers Field, M. Inst., C.E., R. Thorne Thorne, M.B., Professor Prestwick, F.R.S., &c. In addition to the interest taken in the exhibition by medical men, architects, and manufacturers, the general public have recognised the importance of the work thus initiated by the Executive Committee of the Parkes Museum of Hygiene, by subscribing to the Guarantee Fund, which at the meeting of the committee last Tuesday was reported to amount to £1,026 7s. At this meeting the secretary read a letter from Mr. MacCormac, the Hon. Sec. (general) of the International Medical Congress, forwarding the following resolution, which had been unanimously passed by the Executive Council of the International Medical Congress at their last meeting:—"That the sum of £50 be guaranteed to the Committee of the International Medical and Sanitary Exhibition to be held at South Kensington, in connection with the Parkes Museum of Hygiene, on the occasion of the International Medical Congress."

### The Irish Graduates' Association.

THE annual metropolitan dinner of this Association was held on Thursday, March 17th, at the Holborn Restaurant, when the following members and their friends were present:—The President, G. E. Paget, M.D., F.R.S.; Sir Risdon Bennett, M.D.; Dr. Claud Marshall, Mrs. Garrett-Anderson, M.D.; Miss Edith Pechey, M.D.; Miss Annie Barker, M.D.; Dr. Farr, F.R.S.; Dr. Quain, F.R.S.; Dr. Andrew Clark, Dr. B. W. Richardson, F.R.S.; Dr. J. S. Bristowe, Dr. Matthews Duncan, Dr. Habershon, Capt. Jervis White, the Rev. W. H. Stokes, M.A.; W. Canton Dooly, Esq.; Mr. Whitting, G. E. Paget, jun., Esq.; Mr. W. MacCormac, F.R.C.S.; Dr. Thompson, Dr. Balthazar Foster, M.D.; E. Paxton, Esq.; Dr. Tonge Smith, Dr. Davidson, Dr. Donovan, Dr. Kelly, Dr. Vance, Dr. Constable, Dr. Donahoe, Dr. Beamish, Dr.

Hogan, Dr. Daly, A. J. Frazer, Esq.; T. Bullock, Esq. Dr. Tindall Watson, Dr. Powell, Dr. O'Connor, Dr. Hayes, Dr. Ford Anderson, Dr. Milner Fothergill, Dr. Mitchell Bruce, Dr. Stewart, &c. After a very excellent dinner the following toasts were given and responded to:—"Our Rulers—the Queen and Royal Family," by the President; "Our Home Rulers—the Ladies," by the Hon. Sec.; Mrs. Garrett Anderson called on Dr. Andrew Clark to reply. The Chairman then gave "Our Professional Guests," to which Sir Risdon Bennett, Dr. Arthur Farr, and Dr. Bristowe responded. Dr. Balthazar Foster gave "The Unprofessional Guests," to which Mr. Frazer and Mrs. Bullock responded. Dr. Quain gave the next, "Ourselves," coupled with the Health of the President; this toast was drunk with a bowl of punch. Mr. W. Mac-Cormac proposed "Our Elders, the other Learned Societies," to which Dr. Richardson, F.R.S., and Dr. Matthews Duncan, F.R.S., replied. The Hon. Sec. proposed "Our Defenders," coupled with the name of Capt. Jervis White, 77th Regt. Dr. Partridge gave "Our Next Meeting," when it was mentioned that the next meeting would be at Hyde, in August. All the company wore shamrocks, which had been brought from Blarney. The proceedings were marked with great cordiality, and reflected great credit on the Association.

### The Hospital for Incurables, Dublin.

THE vacancy in the office of physician to the Hospital for Incurables, Dublin, caused by the death of Dr. Edward Peele, has been filled up by the election, on Thursday last, of Dr. John H. Chapman, by a majority of 21 to 12. The number of the board of governors—in whom the election lies—is 46, but 34 only were present. Eight candidates offered themselves, and the votes of the board were taken for five, three, and two before the final vote. Dr. Chapman is a Member of the King and Queen's College of Physicians, and a Licentiate of the Royal College of Surgeons in Ireland of twenty years standing; and has been for many years physician to the Donnybrook Dispensary District, and to the Masonic Orphan Boys' School, being also engaged in an extensive private practice in the district in which the Hospital for Incurables is situated. The selection made by the board of governors is an excellent one—not only because Dr. Chapman, by reason of his professional connection with the locality, has special facilities for frequent and punctual attendance at the hospital, but because his seniority and his experience as a practitioner guarantee his perfect fitness for the care of the inmates.

From his professional brethren Dr. Chapman deserves special congratulation, for to him is chiefly due the reconstruction and effective administration of the Irish Medical Association, of which organisation he was the zealous honorary secretary, and is now the president. The time and labour devoted by him to advancing the interests of his medical brethren in Ireland has plainly not interfered with the strictly conscientious and business-like discharge of his duties to his patients, both public and private, and his election on this occasion by so large a majority is a gratifying proof that a physician may take an actively useful position as a public man without in the least forfeiting the confidence of his patients, and that he may have and may express

honestly and plainly his views on public medical questions without being a whit the less efficient or less zealous public servant, and without forfeiting in the least the respect and approval of his superiors in the department in which he works.

### Extraction of Foreign Bodies.

At a recent meeting of the Paris Société de Chirurgie M. Verneuil reported on several cases of foreign bodies introduced into the different orifices of the body, which had been communicated to the Society by various authors.

The first was by Dr. Belgi, of Madeira, on a foreign body in the auditory meatus, which he removed by pouring mercury in the patient's ear, until the foreign body floated out on the surface of the fluid.

The next was Dr. Burcan, who, being unable to extract some larvæ from the auditory meatus of a labourer, conceived the idea of smearing the auricular orifice with honey. The larvæ thus attracted out were easily seized and removed.

M. Dumas, jun., of Montpellier, contributed two cases. The first was that of a child who had got a haricot bean into the nasal fossæ, under the inferior turbinated bone. He was able to push the body backwards into the pharynx, and thus relieve the child. The second case was that of a young girl who had introduced a boot-button into the left nostril, which had penetrated beneath the nasal bones. M. Dumas removed it by means of Hunter's forceps.

The case recorded by Dr. Bernard, of Cannes, was the most interesting of all. It occurred in a woman, aged 65, who was seized in the month of September with pains in the lower part of the belly, accompanied by dysentery. Thanks to astringents and milk diet the dysenteric symptoms disappeared. The abdominal pains, however, persisted, and finally the patient confessed that a hair-pin had been accidentally (!) introduced into the urethra two or three months previously, whence it had probably reached the bladder.

On sounding the patient Dr. Bernard felt the foreign body in the bladder. Arming himself with a hæmostatic forceps he was fortunate enough to seize the body and draw it to the meatus urinarius, where he saw that it was indeed a hair-pin. Not having with him the means to extract it completely, however, he postponed the operation till the next day, taking care to pass a loop of thread so as to keep the pin near. The next day, by help of two small incisions—one on the right, the other on the left—he was able to withdraw it easily. There was considerable concretion on part of both its branches. A few days later the patient was completely cured.

### Iodoform and Alum in Ear Diseases.

DR. SPENCER recommends these remedies in the *American Journal of Otolgy*. Iodoform in powder he finds useful as a direct application in cases of suppuration of the middle ear, especially when ulceration and hyperplastic processes are produced. Even in the case of polypi good results have been obtained. Alum should not be used in acute cases, but kept for chronic ones. Causing coagulation of albuminoid substances, this agent

forms a protective layer on the surface of the ulcers, which favours their cicatrisation. The author does not advise insufflation of these powders, but recommends their application to the affected spot by a cotton-wool carrier.

WE learn with much regret that Mr. Tufnell, of Dublin, on Wednesday last sustained a severe fall down the stairs of the Salt Hill Hotel—fracturing his humerus high up, and also one of his ribs. We are gratified to understand that the injuries have produced no seriously bad effects, and that Mr. Tufnell is as well as is possible under the circumstances.

THE long and distinguished services of Surgeon-Gen. Thomas Longmore, C.B., Hon. Surgeon to the Queen, and Professor of Clinical and Military Surgery at the Army Medical School, Netley, have been recognised by his appointment to the distinguished service reward vacant by the death of Inspector-General Charles Whyte.

THERE was a very excited discussion at the meeting of the Metropolitan Asylums Board on Saturday, on the subject of providing Temporary Hospitals for Infectious Diseases, in consequence of the decision of the Government being against that of the Board in the Fulham case. Appeal No 1 was only carried by the casting vote of the chairman, Dr. Brewer, their being 19 for and against "a further expenditure of the ratepayers money in law proceedings."

OF the zymotic diseases in the large towns last week scarlet fever showed the largest proportional fatality in Oldham, Leicester, Bristol, and Norwich; and whooping-cough in Dublin, Nottingham, Manchester, and Leeds. Of the 23 deaths referred to diphtheria 9 occurred in London and 8 in Glasgow. The death-rate from fever, although generally low, showed excess in Salford, Newcastle-upon-Tyne, Dublin, and Leeds. Small-pox caused 60 more deaths in London and its suburban districts, and one in Manchester, but none in the other large towns.

IN the principal foreign cities, the rates of mortality, according to the latest weekly official return, were:—Calcutta 34, Bombay 31, Madras 43; Paris 33; Geneva 26; Brussels 24; Amsterdam 25, Rotterdam 31, The Hague 22; Copenhagen 24; Stockholm 30, Christiania 20; St. Petersburg 54; Berlin 24, Hamburg 23, Dresden 21, Breslau 32, Munich 23; Vienna 30; Budapest 34; Rome 27; Naples 30, Turin 30, Venice 24; New York 33, Brooklyn 22, Philadelphia 23, Baltimore 19, per 1,000 of the various populations.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

FACULTY LECTURER.—It is announced that the President and Council of the Faculty of Physicians and Surgeons of Glasgow have appointed Mr. D. C. MacVail "Faculty Lecturer" for 1881. This appointment has taken the most intelligent and independent members of the profession in

Glasgow somewhat by surprise. It was understood, hitherto, that this position was reserved for some one of acknowledged pre-eminent ability in a given department of medical science, and that it was intended for the edification of the profession. The subject announced is "The Physiology and Pathology of Respiration." What is the "pathology of respiration?"

ST. ANDREW'S STUDENTS RUSTICATED.—The professors of the University of St. Andrew's have been guilty of the silly act of rustivating five students who took part in a recent Kate Kennedy demonstration. On Monday, the 14th, an indignant meeting of the students was held in the Cross Keys, and largely attended. A memorial was drawn up for opinion of Council. To the honour of one of the professors be it said he strongly dissented from the action of his colleagues.

CHAIR OF PATHOLOGY IN THE UNIVERSITY OF EDINBURGH.—In addition to Dr. D. J. Hamilton, who at present so ably conducts the class, we understand that Dr. Greenfield, Dr. Roy, Dr. Byron Bramwell, Dr. Wyllie, and Dr. Rabagliati are candidates. Our opinion of Dr. Hamilton's pre-eminent claims remains unaltered.

LECTURES ON THROAT DISEASES AT THE GLASGOW ROYAL INFIRMARY.—On Saturday, the 19th inst., Dr. Eben. Watson concluded a highly successful course of lectures on "Diseases of the Throat" at the Glasgow Royal Infirmary. About fifty students attended, many from the Western Infirmary. This must be regarded as satisfactory, as of late years but few students from "the Western" attended "the Royal." We understand that Dr. Watson purposes resuming a practical class on the same subject during the summer months.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—An adjourned meeting of this Society was held in the Faculty Hall, St. Vincent Street, on Friday, the 18th inst., to resume the discussion on Dr. W. L. Reid's paper, "On the Use of Antiseptics in Obstetrical and Gynecological Practice, &c." Dr. George Buchanan occupied the chair. In opening the discussion Dr. Buchanan objected to the title of Dr. Reid's paper, as he contended the parts could not be made aseptic according to Lister's theory. He thought the object and intentions of the paper would be better expressed by its title being, "The Use of Antiseptic Materials in Obstetric Practice." Dr. Sloan also objected in a similar manner to the title of the paper, and evidently desired, however, to retain some belief in the antiseptic theory, while wishing it to embrace such old-fashioned and sensible principles as speedy and thorough contraction of the uterus, scrupulous cleanliness, &c. Dr. Duncan, of Crosshill, in a sensible speech, agreed as to the utter impossibility of using the antiseptic system in midwifery. As for germs, he asserted that they normally existed in the gall-bladder, and other internal cavities of the body totally excluded from air. It was totally impossible to render the interior of the uterus "aseptic." He advised cleanliness, &c., and could not see the use of Dr. Reid's appliances in private practice. Mr. John Reid was sceptical as to the use of antiseptics altogether. Septicæmia was usually due to a retained clot. He considered Dr. Reid's paper Utopian; and that such appliances as he described were calculated to make a serious impression on patients. He referred to the possible medico-legal aspect of the question. Dr. Fleming suggested that if Dr. Reid had used the term "disinfectant" wherever he used the term "antiseptic," he would go along with him. He denied that germs were found in the gall-bladder, &c., in health. He contended that there were two kinds of decomposition, the one chemical, the other decomposition by germs. He regarded the vagina as a closed passage like the urethra. Dr. Stirton emphatically differed from Dr. Fleming as to the normal condition of the vagina, which in certain positions of

the body opened, and could be seen into to the extent of two or three inches. He had that evening seen a patient into whose vagina, when excited, air entered in considerable quantity, and was expelled with disagreeable detonation. He referred to certain experiments with the flame of a lighted candle, which conclusively showed this. The President agreed. Dr. Reid briefly replied. The reading of Dr. Murdoch Cameron's paper "On Uterine Displacements" was postponed. We shall probably revert to this discussion in our next.

**MIDWIFERY CHAIR AT ANDERSON'S COLLEGE.**—We are authorised to state that Dr. Hugh Miller is not a candidate for this Chair. It is understood that he considers his present position a better one. Dr. Robert Bell is also *hors de combat*. It is believed that practically the contest lies between Drs. Wallace and Reid. It is not impossible, however, that the votes may be well divided. When such a struggle is called forth by so small an appointment one cannot help thinking what an amount of toadying and oblique influence would have been banished under the "one portal system," and the universal right to teach.

#### THE LECTURESHIP OF ANATOMY, SURGEON'S HALL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your Northern Correspondent pretends ignorance as to my position to the Lecturers in Surgeon's Hall as an excuse for a feeble witticism. That I can pass over. But his statement that "considering the popularity of the university professor, and of Mr. Symington, the existing extra-mural lecturer on anatomy, intending candidates should think twice before they embark in the expensive luxury of attempting to teach anatomy in Edinburgh" is evidently an attempt to discourage candidates from applying for the lectureship on anatomy at Surgeon's Hall, in other words, it is intimidation. I leave your readers to find fit language to describe the animus which alone could dictate such a paragraph.

I remain, yours &c.,

FRANCIS W. MOINET,  
Sec. to the Lecturers in Surgeon's Hall.

March 17, 1881.

[Dr. Moinet has made a discovery in our paragraph, which was never intended, and omitted the part to which we wished to call attention. We again repeat, to what school is Dr. Moinet the secretary? Does Dr. Moinet forget that there is no school of the College apart from the extra mural school to which Dr. Stevenson Macadam is the recognised secretary? The internal politics of the extra-mural school appear to be somewhat mixed, and perhaps some one more intimately acquainted with them than we are will give our readers the benefit of his knowledge. As far as we are concerned, we beg to assure Dr. Moinet that there was not the slightest animus intended, and that the only object we had in view was asked in our question. Surely Dr. Moinet must know that no remarks of ours would deter any candidate from applying, especially as the candidates are Edinburgh men, and more likely to know the value of their future prospects than we.—NORTHERN CORRESPONDENT, M. P. & C.]

#### POOR-LAW MEDICAL SUPERANNUATION.

THE return moved for by Mr. Meldon, M.P., at the instance of the Irish Medical Association, of the number of Irish Poor-law medical officers who had applied to their boards of guardians for pensions, and the decision of the guardians on these applications, and the reasons given for such decision, was presented to Parliament last week too late

for detailed criticism in our issue of to-day. It is the Irish analogue of a return for England granted last year on the motion of Professor Thorold Rogers, M.P., and it shows that in Ireland, since August, 1869, when the Superannuation Act passed, 188 persons claimed superannuation, of whom 11 were refused for one reason or another, while, in the case of a majority, the pension was cut down by the guardians below the two-thirds of salary which they were authorised to grant. This return, though it places useful information in the hands of those who are engaged in the effort to make a pension a matter of right for the Poor-law medical officer, does not purport to represent in any way the effect of the discretionary power of guardians upon the Poor-law medical system, for it takes no cognisance of those officers who would gladly resign if they dared, and who are compelled to remain in harness because they could not trust themselves to the consideration or sense of justice of their guardians. We have, of course, no means of estimating the probable number of medical officers in this condition of painful suspense, but we can approximate thereto by calculating the number of medical officers who are over 70 years of age and still hold dispensaries, most of whom we may safely assume would gladly be relieved of their toilsome functions if the law afforded a means.

Meanwhile, we observe that the Lord Advocate has introduced a Bill to assimilate the Scotch law to that of Ireland, in other words, to grant to parochial boards that discretion to superannuate their officers of which so much complaint is made in Ireland and England. There is this difference between the cases of Scotland and of England and Ireland, that the Scotch Board receive no state subvention and are under no state control. Nevertheless, it would clearly be very unwise for Scotch medical officers to accept a system of superannuation limited by the good-will of the guardians, especially as they have before them the very unsatisfactory working, as regards the profession, of such system in England and Ireland.

We understand that the Council of the Irish Medical Association, after much negotiation, deliberation, and discussion, has come to a decision as to the provisions of a Bill which will be fairly acceptable to medical officers, and, at the same time, a practicable measure which may be approved by heads of departments and may not provoke the hostility of boards of guardians. When this Bill is formulated we shall lay it before our readers and it will be introduced into the house, and it will then be for Poor law medical officers to bestir themselves if they wish to achieve the object for which they have so long sought.

#### PROFESSOR HELMHOLTZ.

THIS very distinguished physicist is about to visit Dublin, and has undertaken to deliver on the 13th of April at the Royal Dublin Society, a lecture on the "Modern Development of Faraday's Conception of Electricity." Professor Helmholtz will, we believe, be probably the guest of Dr. George Johnston Stoney, F.R.S., Secretary of the Queen's University.

The Council of the Royal College of Surgeons in Ireland resolved on Thursday last to confer on the distinguished visitor its Honorary Fellowship, and an official invitation has been forwarded to him to be present as the guest of the College at the annual dinner of the Council and Examiners club, which will take place within the week of Professor Helmholtz's visit to Dublin.

#### Correspondence.

##### THE DUALITY OF THE CHANCRE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Drysdale, in your impression of the 16th inst., seems inclined to quarrel with the army doctors relative to

their views concerning the condition or nature of a sore which carries with it the true syphilitic virus, in defiance of the splendid researches of Bassereau, and the views of the *élite* in Paris and London. I am fully persuaded that the army surgeons are right and their opponents are wrong. It is now more than seven years ago, when I had nearly a hundred syphilitic patients in my wards at the Sick Asylum, at Highgate, that I gave to this question very considerable attention, and I came to this conclusion after the most careful examination of a large number of patients for a period extending over more than three years, viz., that it did not require a hard Hunterian chancre to produce all the constitutional conditions of syphilisation. That syphilisation may result from a mere abrasion or a soft sore. I have no wish whatever to enter into a controversy upon these points, but I can quite understand a lay committee being confused, as Dr. Drysdale says, in reference to "primary venereal sores." Dr. Drysdale's practice must have been extremely limited, or his power of differentiation extremely dull, if he maintains the doctrine expressed in his letter.

I am, very truly yours,

T. STRETCH DOWSE.

14 Welbeck Street, Cavendish Square,  
March 17, 1881.

University of Dublin.—The following degrees have been conferred during the present month at meetings of the Court of Examiners:—

BACHELOR IN SURGERY.—Austin J. Cockle, John Robert Fraser, Thomas Charles Moore, George de Joncourt Patterson, Godfrey E. Reid, John Ryne, George Scriven, Richard C. Studdert.  
BACHELOR IN MEDICINE.—John Robt. Fraser, Thomas Chas. Moore, Godfrey E. Reid, John Ryne, James Johnston Robinson.  
DOCTOR IN MEDICINE.—William Butler Walsh, John Fitzhenry Woodroffe.

NOTICES TO CORRESPONDENTS.

DR. BERNARD KELLY.—Your case of "Untyptic Pneumonia" shall appear in an early number.

DR. THOMPSON will please receive our best thanks.

DR. J. P.—Certainly an amusing episode, but one which an unscrupulous lawyer might take up on the chance of making heavy fees.

FULHAM.—A note to Dr. Brewer, chairman of the Board, might have the desired effect.

DR. THOMPSON is thanked and referred to another part of present number.

DR. J. G.—'Tis impossible to say anything new on the subject.

"GOING UP" will find Harris and Power's little "Manual for the Physiological Laboratory" of great service to him. We understand there is a new edition of the excellent "Guide" referred to, in the press; our correspondent should get this as soon as out.

DR. C. MCCARTHY'S communication has been unavoidably held over owing to great pressure on our space. Proofs will be sent him in the course of a few days.

POSTAL ALTERATIONS.—It has long been thought that we might have a stamp which should be used either for postage or receipt purposes, but owing, we presume, to these stamps belonging to two different departments, there have been difficulties in the way of making the desired change. Any obstacles, however, that existed have been overcome, and it is now announced that arrangements are being made by which the same penny stamp shall serve both as a postage and as a receipt stamp.

SCOTARIANISM IN MEDICAL CHARITIES.—At a public meeting held at Chelmsford last week to promote the establishment of a cottage hospital there, Dr. Vipan stated that out of 260 cottage hospitals founded in Great Britain, only eight had failed. Those failures were not due to want of funds, but because of theological disputes between members of rival sects.

DR. WILSON, Mr. Hemming, Dr. Norman Conolly, Mr. Morris, see reply to Dr. McCarthy.

A RICH "PAUPER" PATIENT.—The committee of the London Hospital have instructed their solicitor to take out letters of administration to realise the securities amounting to between £300 and £400 which were found concealed in the clothes of a deceased pauper patient, and, after payment of the necessary expenses, to apply it for the benefit of the Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—This day (Wednesday), at 4 p.m., Prof. Henry Tretham Butlin, "On the Relations of Sarcoma to Carcinoma."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—This day (Wednesday), and on Friday, at 5 p.m., Croonian Lectures: Dr. Moxon, "On the Influence of the Circulation upon the Nervous System"

HUNTERIAN SOCIETY.—This evening, at 8, Adjourned Discussion on Dr. Herman's Paper ("Frolopae of the Ovaries").—Mr. McCarthy and Mr. James E. Adams, "On Cases of Varicocoe treated by Excision."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Friday, March 25, at 4 p.m., Prof. F. Treves, "On the Pathology of Scrofulous Affections of Lymphatic Glands."

ROYAL INSTITUTION.—Friday, March 25, at 8 p.m., Mr. A. Buchan, "On Weather and Health of London."

QUEKETT MICROSCOPICAL CLUB.—Friday, March 25, at 8 p.m., Mr. J. G. Waller, "On Cliona Calata: Does the Sponge make 'the Burrows'?"

CLINICAL SOCIETY OF LONDON.—Friday, March 25, at 8.30 p.m., Mr. J. R. A. Douglas, "On Cases of Varix treated by a new Instrument for Obliterating the Veins."—Dr. Whipham and Mr. Rick, "On a Case of Extirpation of the Larynx."—Mr. Spencer Watson, "On a Case of Intra-Cranial Disease Involving several Cranial Nerves."—Dr. B. O'Connor, "On a Case of Syphilitic Psoriasis."

ROYAL INSTITUTION.—Tuesday, March 29, at 8 p.m., Prof. Schäfer, "On the Blood."

VACANCIES.

Bournemouth General Dispensary.—Resident Medical Officer. Salary, £120. Applications to the Treasurer before April 2.

Charing Cross Hospital.—Assistant Surgeon on the Staff. Candidates must possess the F.R.C.S.Eng. Applications to the Secretary before April 2.

Glamorgan Infirmary, Cardiff.—House Surgeon. Salary, £100, with board. Applications, under cover, to the Secretary before Mar. 29.

Greenwich Union.—Assistant Medical Officer. Salary, £100, with board. Applications to the Clerk of the Guardians before Mar. 31.

Royal London Ophthalmic Hospital.—House Surgeon. Full particulars on application to the Secretary.

Royal Westminster Ophthalmic Hospital.—Two Assistant Surgeons on the Staff; must hold the F.R.C.S. Applications to the Committee of Management before March 31. (See Advt.)

St. Mary's Hospital, Paddington.—Ophthalmic Surgeon. Honorary. Applications, under cover, to the Secretary before March 31.

West Sussex Infirmary, Chichester.—House Surgeon and Secretary. Salary, £100, with board. Applications to the Secretary before April 9.

APPOINTMENTS.

HOOPER, E. E., M.R.C.S.E., Medical Officer for the Fourth District of the Reigate Union.

JOHNSTON, E. F.R.C.S. & M.R.C.P., Medical Officer of Health and District Medical Officer of the Melton Union.

KISBY, G., L.F.P.S.G., L.K.Q.C.P.I., Medical Officer to the Seventh District of the Ashton-under-Lyne Union.

MORISON, J. R., M.B., F.R.C.S., L.R.C.P.Ed., Honorary Physician to the Hartlepool Hospital.

MYLES, Dr. W. Z., Senior Assistant to Resident Medical Superintendent, Richmond District Lunatic Asylum, Dublin.

NELL, E. F., M.R.C.S.E., Medical Officer for the Penarth District of the Cardiff Union.

REID, G., M.B., Physician to the Staffordshire General Infirmary.

RUSSELL, W., M.B., Honorary Physician to the Carlisle Dispensary.

SEARLE, G. C., M.R.C.S.E., Medical Officer for the Brixham District of the Totnes Union.

SHORTER, H. G., M.R.C.S.E., Medical Officer to the Hastings Dispensary.

TREHARNE, J. L., M.R.C.S.E., Medical Officer for the Spottland District of the Cardiff Union.

WALSHAM, W. J., F.R.C.S.E., Assistant Surgeon to St. Bartholomew's Hospital.

Births.

BRADY.—At Clonmellon, the wife of P. Brady, M.D., of a daughter.

ELLIS.—Feb. 17, at Sitapur, Oudh, the wife of J. Ellis, M.D., Bengal Medical Service, of a daughter.

LAND.—March 18, at Boryde House, Tonbridge, the wife of W. J. Land, M.R.C.S., of a daughter.

THOMPSON.—March 11, at Killyquade, Newtown, Mountkennedy, the wife of R. Norman Thompson, M.B., of a son.

WINCKWORTH.—March 11, at Sheffield, Beds., the wife of Charles K. Winckworth, L.R.C.P.Lond., &c., of a daughter.

Marriages.

MOORE—ARMSTRONG.—March 15, at Christ Church, Dublin, John W. Moore, F.R.C.P., to Louisa, youngest daughter of the late Edmund J. Armstrong, J.P. and D.L. of Co. Clara.

YEO—SICH.—March 16, at the Parish Church, Chiswick, Robert F. Yeo, Surgeon R.N., only son of Thomas F. Yeo Esq., of Deignay, Co. Wicklow, to Alice, eldest daughter of William Thrale Sich, Esq., of Chiswick.

Deaths.

ADAMS.—March 19, at Stoke Newington, Louisa Stott, wife of Henry Adams, M.R.C.P.

ASHFORD.—March 18, at 7 Windsor Villas, Plymouth, J. Butler Ashford, M.D., aged 59.

BRADY.—March 18, at Upper Baggot Street, Dublin, Luke Brady, L.R.C.S.I., of Newgrove, Co. Clara.

CHENEY.—March 6, at Naples, after four days' illness, of acute meningoccephalitis, George Cheney, M.D.Edin., of 5 Bryanston Street, London, formerly of Mexico.

CHILDS.—March 14, at Tower House, Uxbridge Archibald Prentice Childs, F.R.C.S.Eng.

DAVIDSON.—March 8, at Erith, Kent, James Davidson, M.D., M.R.C.P., Retired Fleet Surgeon, R.N., aged 63.

O'DONNELL.—March 17, at her residence, 4 Gladstone Street, Southwark, London, Rosina O'Donnell (née Maxwell), widow of Dr. H. J. O'Donnell, of Ennis, Co. Clara, in her 56th year.

STACY.—March 12, John Edward Stacy, F.R.C.S.E., of Cavendish Road, Brondesbury, in his 82nd year.

WELCH.—March 17, at 18 Girdler's Road, West Kensington Park, W., Susannah Amelia, wife of J. Welch, M.D.

WHITE.—March 14, at Montague House, Bath, John Ludford White, M.A., F.R.C.S., formerly of Dowlish, aged 67.

**GULSTONIAN LECTURES ON ANÆMIA. (a)**  
By **SIDNEY COUPLAND, M.D., F.R.C.P.,**  
Physician to the Middlesex Hospital.

### LECTURE III.—ABSTRACT.

THE subject of chlorosis was first dealt with, in order to direct attention to the close relations subsisting between it and other forms of idiopathic anæmia; the discovery by Virchow in some cases of apparently congenital defects in the aorta, and its branches being in point of fact, the only stable ground for its separation from them. Those who maintain that chlorosis is a disease *sui generis* regard the anæmia it presents as but one symptom of the disease which is equally marked by nervous and menstrual derangements. But here as elsewhere, the anæmia is paramount, and depended probably by some changes in the hæmatopoietic function. The chief reasons urged for regarding chlorosis as a distinct disease, are its almost complete limitation to the female sex, its apparent connection with the menstrual function and changes undergone at puberty, certain nervous conditions, certain peculiarities in the composition of the blood, and in the structure of the blood vessels. But the female sex itself predisposed to anæmia, and not only the onset of ovulation and menstruation, but the period of their cessation, as well as the period of their activity, sometimes determined anæmia. Moreover, the male, especially in youth, was liable to the development of a disease indistinguishable on other grounds from chlorosis; initiated by like influences, and characterised by similar phenomena. The significance of menstrual derangement had been sometimes narrated; undoubtedly present in many cases, it was almost as often a sequel as an antecedent to the anæmia, and sometimes no irregularity occurred in this function. The nervous characteristics, psychical, emotional, sensorial, were not special to chlorosis in its limited sense, but occurred in cases of idiopathic anæmia, which, from the age or sex of

(a) Delivered before the Royal College of Physicians.

the patient, had been excluded from the category of chlorosis as to the composition of the blood. The limitation of the deficiency in chlorosis to the corpuscular matter, as ascertained by analysis, did not appear to have been disproved in idiopathic or essential anæmia, except in its advanced stages, when the supervention of dropsical effusions indicated diminution in the serum-albumen. Virchow's discovery of a condition of vascular hypoplasia, sometimes associated with an immature condition of the generative organs, or with stunting of the whole body, could not be applied generally. For, in the first place, many chlorotics absolutely recover; the described anomalies are not infrequent (especially the variations in the intercostal arteries) in non-chlorotic subjects, and it was not certain how far the diminution in the calibre of vessels (as of aorta) might be determined by a diminution in their contents. Such conditions, however, were of interest as pointing to an imperfect evolution of the vascular apparatus (as of the blood) frequently underlying the anæmic state; but they cannot well be at the root of all cases. Many etiological factors frequently co-operated in inducing chlorosis, e.g., deprivation of light and air, undue physical exertion, sedentary occupations, &c., factors directly interfering with the blood functions. The symptoms of chlorosis were those of anæmia, even to the occurrence in some cases of a mild irregular pyrexia, comparable to that seen on a more striking scale in "pernicious" anæmia. The characters of the blood in chlorosis were then considered. There is invariably a reduction in the amount of hæmoglobin to the extent of one-half, or even two-thirds; and Quinquad declares there is also a reduction in the chief saline constituents of the corpuscles, but not in their stromal globulin. There is not, as a rule, a corresponding diminution in the number of the corpuscles which, in an average of 18 cases, fell to 65 per cent. the normal. Malassen declares that the corpuscles are larger than in health; and some describe a few globules nearly twice the normal size; but there is always a large proportion of corpuscles below the normal size, and Hayem describes a great excess of hæmatoblasts, as well as variations in stage akin to those met with in pernicious anæmia. Examination of the blood, then, did

not afford any distinctive characters. The effect of treatment was certainly very marked, but this was not held to be sufficient ground for detaching chlorosis from the other and severer forms of idiopathic anæmia. It would seem that in chlorosis the derangement lay mainly in the imperfect evolution of the blood; in the severe forms of anæmia in this factor conjoined with increased destruction. The difficulty in deciding whether a given case of anæmia is one of chlorosis or not is a real difficulty; not a mere question of nomenclature, but enhanced by the attempt to make the term signify more than anæmia without possessing features sufficiently well defined to justify the separation.

The cardio-vascular phenomena of anæmia were then briefly discussed, and the opinion declared that the purely cardiac murmurs were due to actual valvular incompetency produced by the enfeeblement of the cardiac muscle from its imperfect nutrition. The fact of dilatation of the ventricles was not easy of clinical proof, but had been announced by competent authorities; and Pearson Irvine ascribed the murmurs to the eddy of blood in the dilated chambers. Of the arterial murmurs, those in the pulmonary artery and aorta had not been very satisfactorily explained; in other vessels more accessible to the stethoscope, their production was only an exaggeration of that always met with on pressure over the vessel; an exaggeration attributable to diminished tonicity, causing slighter pressure to elicit the bruits. The venous bruits were also in great part ascribed to pressure, and their variations with changes in the velocity of the blood-flow were pointed out. The hypothesis advanced by Dr. Goodhart that anæmia may be the starting point of valvular disease, was mentioned.

The evident connection between fatty degeneration and anæmia was next considered; a degeneration especially marked in the heart, and sometimes in the other muscles, dependent upon imperfections in the normal nutritive changes from lack of oxygen, and cases given in illustration. Similar fatty changes in the lining membrane of blood vessels, and in capillary walls occurred, and to such vascular detritation was ascribed the liability to hæmorrhages, so marked a feature of pernicious anæmia. Fatty changes also occurred sometimes in the liver and kidneys.

In conclusion, the subject of the treatment of anæmia was dealt with. After referring to hygiene and dietetic measures, the hæmaturic drugs were considered, and the rapidity with which iron acted in restoring the corpuscular richness, was illustrated. Arsenic ranks next to iron as a hæmaturic, and in some cases was more efficacious. Phosphorus had been given by Dr. Broadbent with marked effect in a case of idiopathic progressive anæmia. Manganese had been found wanting, and had fallen into disuse. Inhalations of oxygen did not increase the corpuscular richness, although increasing appetite and the power of assimilation (Hayem). Valuable as adjuvants were quinine, strychnine, the mineral acids. Transfusion was the last resort in the pernicious forms of anæmia, and a few successful cases had been recorded, notably by Quincke; but its employment must be had recourse to before the disease is too far advanced, if any permanent effect is to be hoped for. The alternative method of the administration of enemata of defibrinated blood, advocated by the Therapeutical Society of New York, and introduced to the notice of the profession in this country by Dr. Sansom, deserved a careful trial.

#### CASE OF PARACENTESIS OF THE BLADDER. (a)

By F. B. QUINLAN, M.D., Univ. Dub.

THOMAS C., a commercial traveller, stated to be æt. 45, but looking considerably older, was admitted into St. Vincent's Hospital on the evening of the 26th November, 1880, under the following circumstances:—

He had suffered for many years from stricture of the urethra, which sometimes had occasioned retention of urine,

always, however, relieved by catheterisation. On the morning of the day in question he was again so attacked, and adopted the very extraordinary remedy of procuring a quart of whiskey, and drinking as much of it as he could. He became intoxicated, and in the evening was wakened from his drunken slumber by the intolerable pain of aggravated and continued retention in the bladder, irritated by over-indulgence in strong alcohol. He was brought to St. Vincent's Hospital about 9 o'clock p.m., in a most deplorable condition; and in the unavoidable momentary absence of both my surgical colleagues I was, on account of the pressing nature of the emergency, called in by the resident pupil who met me coming home from the opening meeting of this Society, along with Dr. Edward Peele, whose sad and untimely demise is such a source of deep sorrow to us all. I learned from the resident pupil that our house surgeon was already in attendance, and that he had endeavoured without success to pass a catheter, and perceiving on the one hand that operative measures might be necessary, and on the other that I could not procure the aid of my surgical colleagues, whom I am always happy to consult, I requested Dr. Edward Peele to accompany me to the hospital, which, with his usual good nature, he at once did.

On arriving there, I found the patient actually roaring with pain, and tried him with all the ordinary varieties of catheters, hard and soft. The stricture, which was situated at the bulb of the urethra, was cartilaginous and unyielding, and I could not make the slightest entrance into it; the urethra was in a condition of violent spasm, and the only result of my efforts was the production of copious hæmorrhage. Dr. Peele also tried the catheter, but found the passage equally impossible. The condition of the patient was now very serious, the bladder could be felt through the abdominal parietes, which were loaded with fat, like a large hard tense water-melon, and the fundus was level with the umbilicus. As baths, opiates, and other palliative resources had been tried, and as the patient, who implored me to put him out of his agony, could not be left all the night in such a state, Dr. Peele and I decided that the bladder should be tapped, which I at once proceeded to do. I selected a spot in the *linea alba*, two inches above the pubis, where the bladder could be most distinctly felt; and where, from the distention of that viscus, I felt I should be secure from the risk of wounding the peritoneum, reflected from the rectus muscle to the fundus of the bladder. In this spot I plunged the largest-sized trocar and canula (of the ordinary Dieulafoy's aspirator) well into the bladder. On withdrawing the trocar a strong jet of urine squirted forth; and Dr. Peele and I by pressing on the abdomen, emptied the bladder as completely as possible, and to the extent of about forty ounces. The effect was magical; the sufferer expressed himself entirely relieved, and the canula having been withdrawn, he was placed in bed. Hot jars were applied to his feet and sides, and half a grain of acetate of morphia was administered hypodermically. There was still much sanguineous oozing from the urethra, but this we let alone as likely to relieve local irritation and spasm.

Nine a.m., next day. The patient had passed a very comfortable night, and had slept for several hours. He had bled a good deal during the night, and the spasm and irritation were consequently much reduced; and, in a hip bath, he was able to very slowly relieve the bladder *per viam naturalem*. Ordered a suppository containing two-thirds of a grain of acetate of morphia; to drink as little fluid as possible, to apply hot poppy stupes to the perineum, to take very light diet, and to allay his thirst (when excessive) with small fragments of ice allowed to dissolve in the mouth.

For a fortnight this sedative treatment was pursued to the gradual improvement of the urinary stream, until at last he was able to slowly evacuate without the aid of either baths or stupes. It is not necessary to trouble this Society with the details of the dilatation of the very difficult stricture at the bulb of the urethra, or of the simpler one at the junction of the membranous and prostatic portion.

(a) Read before the Surgical Society of Ireland.

This process was accomplished in the ordinary way, and on the 22nd of January the patient left the hospital able to micturate (to use his own expression) as well as in his best days. He had also enrolled himself in the ranks of the total abstainers.

Among the principal reflections derivable from this case is the comparative safety of the supra-pubic operation when performed with a tube of moderate calibre; and I believe that, had it become necessary to repeat the tapping, it could have been done again and even again without much risk. In this case the suction from the aspirator was not employed; and the question arises whether, if it had so been, injury might not have accrued to the interior of the bladder by sucking of the mucous membrane against the sharp edge of the canula. I make this remark with all reserve for I am aware that many most competent surgeons use the exhausted cylinder of the aspirator. When resident pupil in the Richmond Hospital I have seen the late Mr. Edward Hutton perform the supra-pubic operation with exquisite dexterity and with an ordinary ascitic trochar and canula, passing a gum elastic catheter through the latter, which catheter he left in the bladder for several days until he saw his way to the relief of the stricture. Without in the least presuming to be an authority I would deprecate this practice for fear of infiltration, and would much prefer the (if necessary) repeated tapping. With reference to infiltration, it appears to me that the great safety lies in completely emptying the bladder through a small opening. Some hours must elapse before the viscus refills, and in the meantime a plug of lymph will have occluded the opening so as to prevent urinary infiltration. I would further advert to the manner in which the emergency was at the last moment aggravated by the patient's over-indulgence in alcohol, a procedure for which I have not seen in retention cases any parallel, and which at the last moment cut short the time of deliberation and forced me to immediate action.

The great question, however, incidental to this case, is, ought the bladder to have been tapped at all? and could I have relieved the patient by catheterisation? Looking to this question at leisure and with the lights obtained during the dilatation of the stricture, I reply that catheterisation was, on the evening of the 26th of November, impossible, owing partly to the rigid nature of the stricture and partly to the enormous urethral spasm produced by the over-indulgence in alcohol. The element of dreadful pain is also to be considered, for had the pain been only the ordinary suffering of retention I might have leeched the perineum, used copious opiate, and kept the patient in a bath, and thus temporised until the spasm became a little relieved. I might possibly in that way have got an instrument in, although I doubt it. In the present case, however, the patient's agony was appalling to witness; and when I explained to him the risk of tapping he conjured me to do it in language plain enough, but perhaps too forcible for repetition here. Reviewing the case in the full spirit of candour, and not in the least desiring merely to uphold what was done, I conscientiously believe that I had no course open to me but that which was adopted.

#### STIMULANTS IN WORKHOUSES—ALCOHOLIC LIQUORS AS MEDICINES FOR THE SICK.

By NORMAN KERR, M.D., F.L.S., London.

(Continued from page 248.)

As a typical exemplification of the fallacy of drawing a dogmatic conclusion from defective data, let me adduce the interesting statement of the master of the Eton workhouse in a recent number of the Local Government Board *Chronicle*. The cost of ale, brandy, gin, and wine for the sick at Eton for the five years 1871-5, was £541. The cost of the same liquors for the succeeding five years, 1876-80, was £63. The number of deaths during the

first quinquenniad was 168, and during the second 146. Whereupon the worthy master rushes to the conclusion that alcoholic drinks were not beneficial to the health of the sick inmates. Let us see what ground his returns afford for such an assertion. The number of inmates for each year is not given, so there is nothing to show what the percentage of mortality really was. The figures are thus valueless. Even if all the usual particulars were given, and it were shown that the rate of mortality fell simultaneously with the consumption of intoxicating drinks, till we are favoured with the age of each pauper, his state of health, and other circumstances concerning him, in addition to the nature and duration of the disease which killed him, we would be in no position to form a true opinion. Imperfect and useless for the purposes of scientific accuracy as this Eton group of statistics is, an analysis of them as presented to us does not bear out the master's statement. It is true that if we take the sum of the deaths in each quinquenniad, we find an absolute (we have no means of knowing if it is proportionate) decrease, in the whole number, of 22 deaths during the second quinquenniad, when there was a great diminution in the quantity of liquor ordered. But any inference from this crude generalisation would be unwarranted and misleading, for on looking into the master's table of the deaths in each year, I find that the year in which by far the smallest amount of money was spent in intoxicants, in the second quinquenniad, was the very year in which there was the greatest number of deaths. Further, taking the whole ten years, while there were 37 deaths with £7 spent during the year on drink, there were only three deaths more (40) when twenty times that amount (£140) was the outlay!! Again, when the annual alcoholic expenditure was £94, there were 27 deaths during the twelve months, while when the annual expenditure was only £14 there were actually two more deaths (29)!!!

There can be little difference of opinion as to the propriety of limiting the supply of intoxicating liquids to the smallest consumption compatible with safety, and no one can sympathise more warmly than I do with every guardian who is desirous to reduce the expenditure on such articles. That I have done all in my power to arouse public interest in this very important question renders it all the more incumbent on me to insist on zeal being tempered with discretion. Time and again newspapers have been sent to me from different parts of the kingdom, in whose columns I have read with pain most misleading and incorrect statements regarding the practice of certain medical men. In the excess of their zeal some enthusiastic guardians have gravely informed their colleagues that their own local medical officers were behind the age if they did not exclude alcoholic from their practice, an example set "in London by Sir Wm. Gull, Sir Henry Thompson, Dr. Benjamin Richardson, and Dr. Norman Kerr." That the statement is true of Dr. Richardson I know, but it is not true of the others. No one would be more surprised than would either of the two first mentioned gentlemen to hear that he had discarded alcoholic drinks from his practice; and though I very rarely prescribe these potent remedies, and then only with a temporary object, and in definite doses, I emphatically deny the soft impeachment. I would no more dream of proscribing alcohol than I would of proscribing prussic acid.

It will also be seen, from an able article on "Alcohol as an Antispasmodic," in the *Medical Temperance Journal* for January, 1881, that Dr. Richardson himself, in certain cases, recommends considerable doses of alcohol in combination with other medicinal substances.

There are some medical men who concede the prescription of alcohol as alcohol, ethylic or methylic, but object to it in the form of brandy or wine. With this view I have much sympathy, and, wherever practicable, order proof spirit in cinnamon water, with the addition of other aromatics. But I have met with cases in which no preparation of alcohol was retained but old mellow brandy, or other alcoholic liquor; and though I never resort to the wine and the spirit bottle if I can find as satisfactory a re-

medial agent elsewhere, I would be very sorry indeed not to have them at command. Let me entreat our ardent temperance friends, of whose unselfishness and devotion I cannot find words adequately to express my admiration, to be on their guard lest they unintentionally give to professional utterances a meaning these were never intended to convey, and thus hinder, instead of forward, the great cause whose interests we all have so much at heart.
